Osseous Injuries in the Newborn

WILLIAM C. MITCHELL, M.D.
MARK B. COVENTRY, M.D.
Rochester, Minnesota

Masterful neglect as a form of treatment is not often justified in modern medical practice. However, it may be legitimate therapy in certain osseous injuries occurring in newborns. The newborn has such tremendous power to form callus and heal bone that nonunion of fractures is almost unknown. Extensive angulation and shortening usually are corrected by subsequent growth. The authors outline the management of osseous injuries for which treatment is indicated.

TRAUMA to the skeleton of the newborn infant is of interest to the family physician, obstetrician, pediatrician and orthopedist. The diagnosis is rarely difficult if the examiner is thorough and understands the skeletal development in the newborn. He also should appreciate the manner in which the periosteum and soft tissues may react to trauma. With proper diagnosis and adequate treatment, the results are excellent in a majority of cases. The newborn infant has a propensity for the formation of callus and healing of fractures. Subsequent growth usually restores angulation deformities.

Since the time factor may be extremely important in breech deliveries, the obstetrician may deliberately fracture the clavicle or humerus in difficult deliveries. The clavicle also may be deliberately fractured in shoulder dystocia encountered in infants of excessive size. It is obviously better to incur osseous injury than to risk serious anoxia with impaired cerebral function or even loss of the baby.

Watson-Jones[1] presented a classification that includes the following: fracture or epiphysial displacement from injury sustained in a difficult delivery, multiple fractures associated with congenital fragility, and fractures of the tibia associated with congenital pseudarthrosis. To this list we would add "traumatic ossifying periostitis," or "periosteal stripping," as described by Snedecor and Wilson.[2] Fragilitas ossium, congenital pseudarthrosis, and congenital dislocation of the knee and hip will not be considered. They present totally different problems in etiology and management.

One should be familiar with the normal variations in the newborn before any angular or rotational deformity is ascribed to trauma. Blount[3] noted that the newborn baby has flexed knees and hips. The knees are rotated externally while the feet are rotated inwardly, and lateral bowing of the femur and tibia is evident. These physiologic "deformities" normally are corrected in the first two years of life.

Obstetric palsy should be mentioned, since it may be due to a nerve injury from trauma about the shoulder joint and may present a confusing clinical picture. Also, injury to both bone and the brachial plexus may occur. In obstetric palsy, flaccid paralysis of the upper extremity is present, and the shoulder is internally rotated and abducted. The elbow is usually flexed, and the wrist is flexed and pronated. Duchienne, in 1861, as noted by Speed and Knight,[4] stated that posterior dislocation of the shoulder occurs in some of these infants and that lateral displacement and retroversion of the epiphysis are the usual finding. Blount[3] mentioned that a nerve lesion may be accompanied by dislocation of the shoulder that is spontaneously reduced before examination; one should avoid abduction in a splint if this condition is suspected to be present. Roentgenograms will help rule out dislocation and injury to bone and should be taken in all cases of birth palsy.

TRAUMA to the skeleton of the newborn infant is of interest to the family physician, obstetrician, pediatrician and orthopedist. The diagnosis is rarely difficult if the examiner is thorough and understands the skeletal development in the newborn. He also should appreciate the manner in which the periosteum and soft tissues may react to trauma. With proper diagnosis and adequate treatment, the results are excellent in a majority of cases. The newborn infant has a propensity for the formation of callus and healing of fractures. Subsequent growth usually restores angulation deformities.

Since the time factor may be extremely important in breech deliveries, the obstetrician may deliberately fracture the clavicle or humerus in difficult deliveries. The clavicle also may be deliberately fractured in shoulder dystocia encountered in infants of excessive size. It is obviously better to incur osseous injury than to risk serious anoxia with impaired cerebral function or even loss of the baby.

Watson-Jones[1] presented a classification that includes the following: fracture or epiphysial displacement from injury sustained in a difficult delivery, multiple fractures associated with congenital fragility, and fractures of the tibia associated with congenital pseudarthrosis. To this list we would add "traumatic ossifying periostitis," or "periosteal stripping," as described by Snedecor and Wilson.[2] Fragilitas ossium, congenital pseudarthrosis, and congenital dislocation of the knee and hip will not be considered. They present totally different problems in etiology and management.

One should be familiar with the normal variations in the newborn before any angular or rotational deformity is ascribed to trauma. Blount[3] noted that the newborn baby has flexed knees and hips. The knees are rotated externally while the feet are rotated inwardly, and lateral bowing of the femur and tibia is evident. These physiologic "deformities" normally are corrected in the first two years of life.

Obstetric palsy should be mentioned, since it may be due to a nerve injury from trauma about the shoulder joint and may present a confusing clinical picture. Also, injury to both bone and the brachial plexus may occur. In obstetric palsy, flaccid paralysis of the upper extremity is present, and the shoulder is internally rotated and abducted. The elbow is usually flexed, and the wrist is flexed and pronated. Duchienne, in 1861, as noted by Speed and Knight,[4] stated that posterior dislocation of the shoulder occurs in some of these infants and that lateral displacement and retroversion of the epiphysis are the usual finding. Blount[3] mentioned that a nerve lesion may be accompanied by dislocation of the shoulder that is spontaneously reduced before examination; one should avoid abduction in a splint if this condition is suspected to be present. Roentgenograms will help rule out dislocation and injury to bone and should be taken in all cases of birth palsy.

Fractures of the Long Bones

Authors disagree as to the usual order of frequency of fractures of long bones. Watson-Jones reported that fractures of the shaft of the humerus

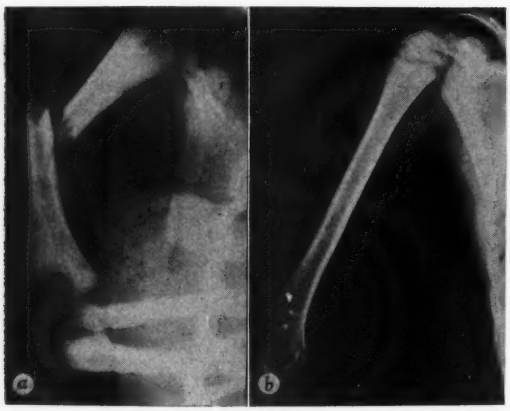

Fig. 1. Fracture of right humerus. *(a)* Appearance immediately after birth. *(b)* Appearance five and one-half years after treatment. A Velpeau swathe was used and no attempt at correction of position was made.

are most frequent. Madsen[5] and Snedecor and Wilson mentioned that fracture of one or both clavicles is noted most often. Following these, fracture of the shaft of the femur and displacement of the epiphysis of the humerus or the femur occur in that order. Depressed fracture of the skull is noted occasionally but is not ordinarily of serious significance and will not be discussed.

Madsen, in 1955, reported an analysis of 786 fractures among 105,119 newborns. Fracture of the clavicle was the most common, numbering 726 instances; forty-one fractures of the humeral shaft and twenty-five fractures of the femur were found. Follow-up studies in twenty-six cases of the shaft fractures demonstrated radiologic evidence of the fracture even after thirty years. Harris and Steinberg,[6] in a study of abnormalities observed during the first six days of life in 8,716 live-born infants, noted sixteen fractures; fourteen involved the clavicle, one the femoral shaft and one the parietal region of the skull.

Fractures of the shaft are usually complete and may have considerable displacement. The first evidence of injury may be the tumor formed by the callus two to three weeks after delivery. Callus may be seen roentgenographically as early as the fifth day, and it is usually decreasing by the eighteenth day. By the end of three months, the bone usually is normally healed. Nonunion is seen rarely, and remodeling in the first few years of life will restore angulation deformities. About one fourth of the fractures of long bones occur in infants with cephalic presentation; the remainder are seen in breech deliveries. The mother is usually primiparous, and most of the infants are not exceptionally large at birth.

Fracture of the Shaft of the Humerus.—These usually occur in the middle third of the humerus and are transverse or spiral (Fig. 1). They frequently display anterolateral angulation. They may occur during breech delivery, the mechanism being traction on the extended arms. The mechanism in vertex presentations is usually axillary traction as the impacted shoulder is delivered. The proximal fragment is often abducted by the pull of the deltoid muscle. Palsy of the radial nerve frequently is noted but spontaneous recovery usually takes place.

Treatment should not be strenuous. The bone will heal and correct any angulation in time. The arm may be strapped to the thorax over a pad thick enough to cause moderate abduction, or the arm may be abducted with sandbags for about a week. At the end of this time, the fracture is usually "sticky" and pain is minimal.

The prognosis is usually excellent whatever treatment is chosen. Perfect remodeling may be noted even with 40 to 50 degrees of outward angulation. Shortening and angulation are usually relieved in the first two years.

Fractures of the Clavicle.—These fractures are usually in the midshaft of the bone and frequently are caused by digital pressure in delivering the aftercoming head and sometimes in the rotation of shoulders or by compression in shoulder dystocia of large babies. Callus appearing in two to three weeks may be the first indication of injury, or the infant may not move the extremity normally. Treatment is unnecessary.

Fractures of the Shaft of the Femur.—These fractures are usually transverse and in the middle third of the bone. The mechanism is said to be torsion of the presenting leg in breech deliveries or internal podalic version. The psoas muscle causes the proximal fragment to be strongly flexed and at a right angle to the distal fragment, thereby displacing the bone fragments.

Fractures of the femoral shaft require treatment. If the limb is extended in a Thomas splint

or a plaster cast, the fragments will unite with considerable forward angulation. If the limb is bandaged to the infant's body with the hip fully flexed, shortening will not be corrected.

Bryant's traction appears to be the most rational form of treatment. The limb is held at a right angle to the trunk, in the same axis that the proximal fragment is held by the psoas muscle. In this manner, alignment is maintained. Length is preserved by traction. It is practical treatment from a nursing standpoint. An efficient restraint is necessary across the trunk, and it is better to use separate weights and pulleys for each limb. As much as 1 cm. of overriding is acceptable, as is 20 degrees of posterior angulation. Extreme care must be exercised to guard against circulatory embarrassment from the cutaneous traction and bandages. Pain, pallor or cyanosis, and swelling of the feet are signs of danger. Union of fractures of the femoral shaft may occur in two weeks, but traction should be maintained until the callus is no longer tender, which usually is about three weeks from the time of fracture.

Periosteal Stripping and Epiphysial Displacement

Periosteal stripping may result from the trauma of a difficult delivery, such as a breech presentation in a primiparous mother. On the day following delivery, the extremities may be tender and swollen, and passive motion may produce pain. Roentgenograms are usually normal at this time; however, if others are taken in five to seven days, dense shadows of calcification are seen about the epiphyses, or subperiosteally, if the muscles and periosteum have pulled away from the bone (Fig. 2). Even complete separation of the epiphysis may occur. The proliferative calcification may be expected to resorb in three to five months. Specific treatment is not indicated and the prognosis is good.

Snedecor and Wilson, in 1949, reported their observations on fifty consecutive infants delivered from breech presentations. Roentgenograms were made on the seventh postnatal day. There was evidence of subperiosteal or epiphysial hemorrhage in 6 per cent of these infants, and an equal number had soft-tissue injuries. Since the epiphyses are the weakest point of the long bones, these authors considered that traumatic deliveries often caused subperiosteal stripping of adjacent tissues. Proliferative calcification takes place in the hemorrhagic zone in five to ten days and becomes evident on the roentgenogram.

Epiphysial displacements usually are noted in the lower part of the femur or in the upper or lower part of the humerus. The trauma incident to breech extraction is usually responsible for epiphysial separation. The obstetrician may hear or feel the shaft of a bone "crack" but may be unaware of an epiphysial injury. The soft tissues are often tense and swollen and may be reddened. Pain frequently abates by the time roentgenologic evidence of injury appears. If displacement is absent or minimal, treatment is not needed. In the occasional infant with displacement of the epiphysis, gentle manipulation and splinting are the best treatment.

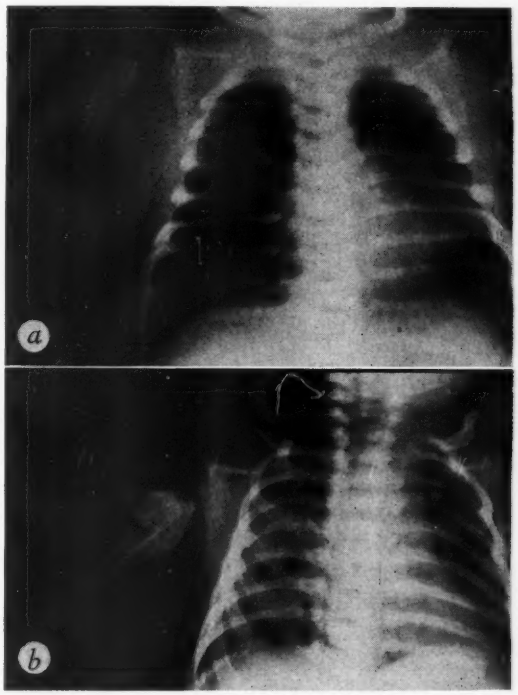

Fig. 2. *(a)* Appearance immediately after birth. *(b)* One month later, the same region shows subperiosteal and epiphysial calcification.

Lower Femoral Epiphysis.—Displacement is obvious in the roentgenogram, since this epiphysis is present at birth. The periosteum is stripped and displaced backward with the epiphysis. If not corrected, the hematoma may ossify, forming a new shaft. Even with this deformity, the roentgenogram may appear normal after two or three years. The infant should be placed in a Bryant

traction frame for two or three weeks. Traction is important before the knee is extended in order to prevent damage to the popliteal vessels.

Upper Femoral Epiphysis.—Traumatic separation of the upper femoral epiphysis as a birth injury is rare. Baron and associates,[7] in 1951, stated that twenty cases had been reported up to 1944, all in conjunction with breech presentation. Forceful manipulation of the infant's leg is the usual cause. Kennedy[8] suggested that the infant should be examined more carefully in difficult and traumatic deliveries; if version and extraction are done, serial roentgenograms should be obtained for at least three weeks after birth. Slight shortening, limited active and painful passive motion, external-rotation deformity of the extremities and, occasionally, discoloration of the thigh are evident. Roentgenologic examination is essential for diagnosis. Proximal displacement of the diaphysis, formation of callus, subperiosteal reaction, premature ossification of the capital epiphysis and accelerated growth of the neck may be seen on the roentgenograms. Baron and co-workers determined that the most stable position for the epiphysis was flexion of the thigh to 90 degrees and abduction to 40 degrees. This was determined on the basis of studies on cadavers. They recommend use of a spica cast for six weeks. Bryant's traction may be used as well. Coxa vara and degenerative changes may be late sequelae.

Lower Humeral Epiphysis.—The center of ossification of the lower humeral epiphysis does not appear until the latter half of the first year. Roentgenograms are not diagnostic until ten to fourteen days after injury, at which time evidence of ossification in the reactive callus becomes visible. The clinical diagnosis is based on pain, swelling and immobility of the extremity. Treatment is best effected by traction, followed by 90 degrees of elbow flexion, the forearm being placed in a sling. Even with imperfect reduction, the regenerative process usually results in full anatomic correction.

Upper Humeral Epiphysis.—The probable cause of this injury is strong traction during breech delivery. Shulman and Terhune[9] reported that this is more frequent than is injury to the lower humeral epiphysis. Fracture of the clavicle, or shaft of the humerus, and obstetric palsy must be differentiated by physical examination and roentgenograms. The examiner may be presented with the situation of injury to both bone and the brachial plexus, as already mentioned.

Treatment of separation of the upper humeral epiphysis requires only immobilization and rest. Brief lateral traction with the side of the crib elevated is sometimes helpful, but use of a collar and cuff is usually sufficient.

Summary and Conclusions

Injury to the bones and epiphyses of the newborn is of interest and importance to a wide segment of the medical profession.

Primiparous mothers with difficult breech deliveries constitute the largest group with which such injuries are associated. Torsion, traction and digital pressure are the usual mechanisms of injury. The fracture may be induced deliberately to facilitate delivery of the baby.

The newborn has such unique propensity for the formation of callus and healing of bones that nonunion is almost unknown. Shortening, and angulation of even 40 to 50 degrees usually are corrected by subsequent growth.

Fractures of the femoral shaft require active treatment. Bryant's traction gives excellent results if used properly.

Traumatic deliveries may cause epiphysial or subperiosteal hemorrhage presenting clinical symptoms; however, roentgenographic evidence of injury may not be present until proliferative calcification occurs in the hematoma, which may take five to seven days. Such injuries apparently all heal without residual deformity.

Review of Twenty Years of Colon Surgery

With an Analysis of Colon Anastomosis by the Murphy Button Technique

JAMES A. JOHNSON, M.D.
Minneapolis, Minnesota

BEFORE the days of our present knowledge of antibiotics, judicious use of blood transfusions, and modern anesthesia, primary resection of the colon was a hazardous undertaking and carried a high mortality. Mummery,[1] in 1923, collected eighty-six cases with primary anastomosis resulting in a mortality of 37 per cent, which was about the mortality range at that time in the hands of the best surgeons.

Various extra-peritoneal operations were therefore devised and came into common use. For example, for carcinomas of the rectum the Kraski two-stage operation was the one usually used; in the colon, itself, some type of exteriosation operation was done—mostly the so-called Paul or Mikulicz procedure in which the lesion and bowel were brought out of the abdomen and the lesion was at once or later resected and the anastomosis performed at a later stage. This proved on the whole to be very satisfactory but, of course, involved several stages and caused considerable disability of the patient for a long time, and an adequate dissection could not be done.

A review of lesions of the colon operated upon during the past twenty years (1936 through 1956) has been made. During this period, the author operated upon 189 cases. Forty cases were not operable and only palliative operations were done, such as short circuit to relieve obstruction, permanent colostomy with or without cautery, or cautery alone if it was carcinoma of the rectum.[2,3] In the remainder, various techniques were used, such as those recently described. The two-stage Mikulicz was used in the colon and the abdominoperineal resection for low sigmoid and rectum was used in most instances, while in only ten, the Kraski operation was done.

The etiology of carcinoma of the colon is no more clearly understood than is that of carcinoma of other parts of the body. However, we have certain contributing factors—especially the situation where polyps are present. It has become increasingly certain that polyps in the colon will undergo malignant changes, and this is probably much more often the primary cause than is still generally understood.

There are four types of carcinomas of the colon:

1. The raised polypoid growth which grows into the lumen of the bowel and often gives rise to early symptoms, especially the passing of mucus and blood or signs of obstruction. As a rule these are among the less malignant, and because of their symptoms patients often seek early relief.

2. The ulcerating crater-like growth with a nodular margin. These penetrate deep into the surrounding structures, often are late in producing symptoms and relatively early in invading the lymphatics and the blood stream, and also tend to penetrate the bowel wall.

3. The annular constricting growths which con-

From the Nicollet Clinic, 1009 Nicollet Avenue, Minneapolis 3, Minnesota.
Presented before the Minnesota Academy of Medicine, April 10, 1957.

tain a large amount of fibrous tissue, and cause early constriction of the bowel. Occasionally acute intestinal obstruction is the first serious symptom.

4. The soft, gelatinous or coloid growths either single or multiple. These are not common but are rapidly growing and highly malignant.

The methods of spread are:

1. By direct penetration through the bowel wall and invading the surrounding structures or shedding of cells into the general peritoneal cavity so that numerous transplants take place later on.

2. Spread into the adjacent lymphatics. This is perhaps one of the most common and may also occur with any of the other known spreads.

3. Direct spread into blood vessels and therefore early wide dissemination of the growth. Madison, Dockerty, and Waugh[4] proved that by injecting the veins in specimens of carcinomas of the rectum with radio-opaque material, they could demonstrate the plugging of the veins and prove this by microscopic examination to be carcinoma. Grinnell[5] found venous invasion in 14 to 36 per cent of removed surgical specimens of the colon and rectum.

4. A spread directly along the bowel wall, the so-called intramural spread. Robert S. Grinnell[6] found that retrograde intramural spread was from 1 to 7 cm. in eight of the ninety-three carcinomas located 5 to 18 cm. from the dentate line. This is interesting because it becomes necessary to do a fairly wide resection particularly in rectal carcinomas.

The symptoms depend upon the location of the lesion. For example, carcinomas of the rectum and low sigmoid where about 70 per cent of carcinomas occur, the early symptoms are those of bleeding and passing of mucus. In the cecum and the right colon, the symptoms are not very evident over long periods of time. Early obstruction is very uncommon. The usual symptoms are those of anemia, gradual loss of weight, and these are often mistaken for ordinary cases of anemia. Elsewhere in the colon there may be symptoms of constipation, and this may lead to an early examination to make the proper diagnosis.

Diagnosis

Although we now have the proctosigmoidoscope and very good x-ray examinations, diagnosis comes too late in many cases. This is usually due to the patient who pays too little attention to the symptoms, or else is due to the physician who does not follow up his cases properly. It is well to do a routine proctosigmoidoscopic examination. It is easy to do and gives the best information in the rectum and lower sigmoid. There are other lesions, such as polyps, that can easily be eradicated through the proctoscope with subsequent microscopic study being made. X-ray examination alone is not very satisfactory in the lower bowel and therefore proctoscopic examination has to be depended upon. X-ray should be carried out with a good deal of care. It is well to do a contrast barium enema. If there are any suspicious symptoms, even though the x-ray may not show anything, such a patient should be rechecked at once and again within a month because it is very easy to overlook carcinomas, particularly in the sigmoid and cecum. A much neglected test for occult blood in the stool may prove valuable in many cases. This should be done as a routine procedure in all suspicious cases.

TABLE II. CARCINOMA LOCATION

	Operable	Palliative	Total
Lower sigmoid	23	4	27
Mid and upper sigmoid	4	1	5
Cecum and ascending colon	11	5	16
Transverse colon	8	3	11
Splenic flexure	1	0	1
Total	47	13	60

Treatment

Indeed a new era has developed in surgery of the colon since the discovery and judicious use of antibiotic drugs, blood transfusions and modern anesthesia. It is difficult to understand now the trouble that we used to have many years ago. The mortality now, because of this new era of treatment, has been reduced to a very low level in cases that are fair risks and do not have other combined lesions. Much has been done during the past ten years to improve the technique and to understand the use of physiologic chemistry in combatting depletions of these patients previous to and after the operation.

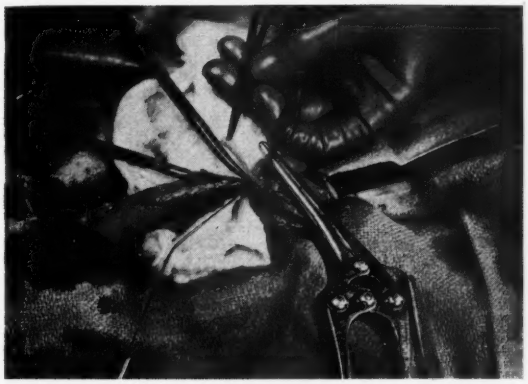

Fig. 1. The purse string silk suture has been placed in the proximal end and the crushed portion is being cut off.

Resection of colon by application of the Murphy button technique.—This is not new but it has not, we believe, been used to any extent in colon resection. During the years the author was associated with Dr. Murphy (1910-1915), we used the button mostly in gastroenterostomies and in the small bowel. I had never seen him use it in a colon resection.

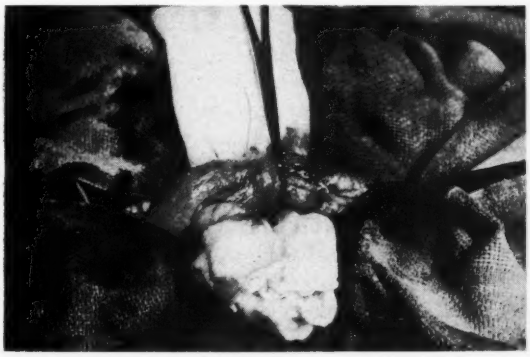

Fig. 3. The button has been closed so that there is a tight anastomosis of end of ileum to end of transverse colon—in a right colon resection.

I continued to use the Murphy button in various parts of the gastrointestinal tract; such as, the small bowel and the right colon, for many years. On May 12, 1937,[7] I read a paper before the Minnesota Academy of Medicine in which I described the application of the button in a resection of a carcinoma of the jejunum. Although I had used it off and on during the years, the first record I have of using it on the colon was in a case of resection of the right colon on a Mrs. G. H., December 11, 1940, with carcinoma of the cecum. Since then I have used it in all parts of the colon, especially in bad risk cases. Before bowel antibiotics it was very useful because if carefully done it essentially became a closed technique without soiling. I have now used it as an operative procedure in all parts of the colon in eighty-one cases. Sixty were carcinoma and twenty-one were non-malignant. Let it be clearly understood that this is only another method and it does not need to replace the suture method.

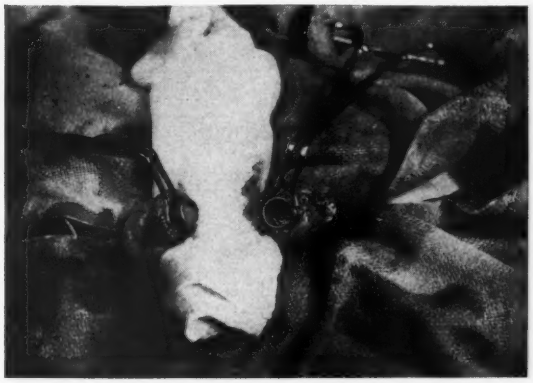

Fig. 2. The purse string suture has been tied and the button forceps applied.

However, the Murphy button technique has some advantages, we believe, in special cases. There is no leakage if the circulation is adequate.

Fig. 4. A continuous 4-0 intestinal chromic is being applied. This is to be followed by fine interrupted silk sutures.

The bowel lumen heals without a scar. There is no suture of the mucous membrane, and this obviates, in all probability, local recurrences of carcinoma in the suture line. Cole[8] observed in fifty-five consecutive cases with colon resection, 16 per cent local recurrence—two-thirds of these were at the suture line. The button technique can be

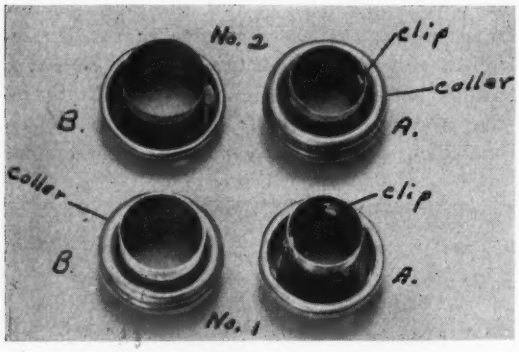

Fig. 5. Illustration of Button. No. 1 button is correct. The clips are on the male (a) part of the button and the collar and spring on the female (b) part. Therefore, the button closes firmly on both ends of the bowel. No. 2 button is incorrect. The collar and spring are on the male (a) part of the button and there is, therefore, no clearance to close the button.

To illustrate the technique, a cloth tube can be made to represent the bowel. The silk purse string is placed and the button tied into each end. The button is then engaged and closed. The cloth is not as thick as the bowel but it will show the technique and reveal the correct and incorrect button.

used in colon obstruction without preparation or a preliminary colostomy. It is easier to do in carcinomas low in the sigmoid, especially when the patient is quite obese.

Technique

General points in the technique: Tie off the colon above and below the lesion to prevent any cell spread along the lumen during the surgical procedure. Tie off the circulation at its source to prevent spread through the vessels. Perform a thorough removal of the glands into which the lesion drains, proceeding with the usual resection which is now standard for all colon surgery.

For the Murphy button technique: (1) Choose a button to fit the bowel, usually a 22 mm. button is used in the right colon, and a 24 mm. button in the sigmoid or end-to-end of the colon elsewhere. (2) After the bowel has been resected and the clamps are on the remaining ends, a No. 2-0 silk purse string suture is placed in the end of the bowel on both sides. (3) Trim off the crushed bowel that has been destroyed by the clamp. (4) Grasp the shaft of the button with a forceps and insert it into both ends. Tie it in and apply the button forceps to hold it in place. (5) The male part of the button should be in the proximal bowel. (6) Engage the button while removing the forceps. After the forceps have been removed, press the button firmly together. My button forceps have been made at an angle, as illustrated in Figure 2, so they can be used deep down in the pelvis or any other locality where a straight forceps would be cumbersome. (7) Reinforce the anastomosis with one row of continuous 4-0 intestinal chronic catgut and one row of interrupted fine silk.

TABLE III. CARCINOMA OF LOWER SIGMOID—RESULTS

Number of Patients	Living and Well	Survival
Operable—23	16	7 (8 to 11 yrs.) 5 (5 to 7 yrs.) 4 (2 to 4 yrs.)
		2 died other causes (6½ yrs. and 8½ yrs.)
Palliative—4		3 lived 4 to 18 months. 1 died following operation (cerebral thrombosis).

TABLE IV. CARCINOMA OF MID AND UPPER SIGMOID—RESULTS

Number of Patients	Living and Well	Survival
Operable—4	2	2 (8 yrs.) 1 died 6½ yrs. from melanoma 1 died 3 yrs. from metastasis
Palliative—1	1	18 months

The button usually releases itself about the tenth day. A few in the low sigmoid have passed on the fifth to eighth day. The longest has been twenty-three days. It often becomes loose in the bowel and passes into the rectal pouch where it can usually be felt by finger examination. In none of my cases has a button failed to pass.

A word of caution, however. Many of the buttons in the market today are incorrectly made. Figure 5 shows the correct and incorrect design. If the wrong button is used, it will not close tightly on the ends of the bowel.

Results

The cases considered operable were those in which the lesion and metastatic areas could be removed. The cases considered palliative were those in which metastatic lesions could not be removed because they were in the liver or widespread in the abdomen, and only resection of the lesion itself or a short circuit operation could be done to relieve or prevent obstruction.

All but one of the cases were followed. An eighty-year-old, senile woman who was taken to a rest home, could not be traced. The average age was sixty-nine; the youngest thirty-two and the

adenoma of the pancreas at eighty-eight years of age. In both, postmortem examination showed no carcinoma. One died six-and-a-half years after carcinoma from melanoma. The number of cases presented here is small but the main object is to present this as a method of colon resection and to describe the technique.

It must be remembered that often the Murphy button technique was used in the extremely bad risk cases. There was mortality in four cases as follows:

Case 1.—Mr. S., aged seventy-four. Operated for carcinoma of the sigmoid with obstruction on October 7, 1947. Well until September 10, 1949. Admitted with carcinoma of the transverse colon and ileum. Both resected. Died twenty-four hours postoperatively from cerebral hemorrhage.

Case 2.—Mrs. W., aged sixty-five. Three years of symptoms. Operated for carcinoma of the sigmoid, October 4, 1948. Palliative operation for obstruction—died twenty-four hours postoperatively. Postmortem: Infarction at brain stem; atelectasis. Never rallied after operation.

Case 3.—Mr. H., aged seventy-one. Operated for carcinoma of the sigmoid, March 28, 1955. Died of uremia. Blood urea nitrogen 217 mg., probably resulting from transfusion. Postmortem: Bilateral atelectasis.

Case 4.—Mr. J., aged fifty-nine. Operated for obstructing carcinoma of the cecum with perforation and abscess. Poor liver function, extensive weight loss. Died of atelectasis and circulatory collapse. Abdomen remained normal.

There was no mortality in the twenty-one cases operated upon for non-cancerous lesions. (Of course, there should not have been any because

TABLE VI. CARCINOMA OF TRANSVERSE COLON—RESULTS

Number of Patients	Living and Well	Survival
Operable—8	5	1 (8 yrs.) 3 (5 to 7 yrs.) 1 (2 yrs.) 1 died, 2 yrs. lung metastasis 1 left hospital o.k. (senile), could not be followed

they were not depleted like advanced cancer cases are.) It is quite apparent that these cancer patients died primarily as a result of their poor condition and not from the surgery.

Conclusion

1. A review of twenty years of surgery of the colon has been presented.

2. In eighty-one cases the anastomosis was done by the Murphy button technique. Sixty of these were carcinoma and twenty-one were not malignant.

3. A follow-up and analysis has been done of the carcinoma cases.

4. The technique has been presented quite in detail so that anyone who chooses to use this method should be properly informed.

The Prognostic Value of Leukocy udi
Treated with Rad osp

● *Studies of leukocytic activity in polycythemia vera allow classification of the disease into four subdivisions. This is of some prognostic importance, as the incidence of long remissions is much higher when the polycythemia is of the simple type. When granulocytic hyperplasia is present, the incidence of therapeutic failure is higher, more radiophosphorus is needed for control, and the greater is the chance for development of either a leukemoid state or acute leukemia.*

EXPERIENCE with radiophosphorus in the treatment of polycythemia vera shows considerable variability in response and outcome in individual cases. Objective remissions of at least one year's duration have occurred in 74 per cent of the treated patients: 45 per cent obtained remissions lasting from one to two years as a rule, and 29 per cent obtained remissions of three years or more; 26 per cent failed to obtain adequate remissions.

There were eighty deaths among 230 patients whose fate was known as of January 1, 1956. Twenty per cent of the deaths were caused by acute leukemia and 32 per cent by various chronic leukemoid states such as myeloid metaplasia or chronic myelocytic leukemia. Another seventeen patients were known to be living with the chronic leukemoid states.

The purpose of our study was to determine whether or not any features seen on initial examination of the patient would cast light on the extent of remission, on individual sensitivity to radiophosphorus, and on the patient's ultimate fate.

Initial factors such as size of the spleen, erythrocytic volume, plasma volume, leukocyte count, platelet count, uric acid metabolism, and previous duration and treatment of polycythemia vera were considered. Size of the spleen and uric acid metabolism are related as single features when they are of considerable magnitude; and, of course, they are related to leukocytic activity. Patients who had experienced long duration of polycythemia vera prior to treatment with radiophosphorus also showed evidence of increased leukocytic activity, as did patients who had had extended treatment with phlebotomies or phenylhydrazine. The initial height of erythrocytic and plasma volumes does not seem to have any prognostic value nor does the platelet count.

Evidence of leukocytic activity seems to be the most indicative single feature. Our basis of reporting is based on quantitative and differential leukocyte counts in the peripheral blood as these are technically easy to obtain and available to us in subsequent reports from elsewhere.

Our method of reporting leukocyte values requires explanation. The leukocyte count as commonly used is relative to the total blood volume. If we are to evaluate leukocytosis in a disease in which total blood volume is affected, as it is in polycythemia vera, the leukocyte count must be reported in absolute terms. This may be effected by multiplying the white blood cell count per cubic centimeter by the total blood volume per kilogram of body weight.

Thus, relative leukocyte counts of less than

ocytudies in Polycythemia Vera
Radiophosphorus

CHARLES F. STROEBEL, M.D.
DAVID G. HANLON, M.D.
Rochester, Minnesota

15,000 cells per cubic millimeter are converted into two classes: the class in which the number of circulating leukocytes is 10^9 or less per kilogram, which we consider to be in the normal absolute leukocyte range; and the class in which the number of circulating leukocytes, although occult to the ordinary methods of counting, is more than 10^9 per kilogram, which we consider to be in the range of absolute leukocytosis.

Counts of more than 15,000 leukocytes per cubic millimeter are obviously increased by both relative and absolute standards.

Cases showing myeloid immaturity in excess of 1 per cent of the differential leukocyte count are considered separately.

This gives us the following fourfold classification of polycythemia vera: (1) simple polycythemia vera, (2) occult leukocytic polycythemia vera, (3) gross leukocytic polycythemia vera and (4) leukemoid polycythemia vera. In simple polycythemia vera the absolute leukocyte count is 10^9 or less circulating leukocytes per kilogram. Myeloid immaturity in the peripheral blood does not exceed 1 per cent. In occult leukocytic polycythemia vera the absolute leukocyte count exceeds 10^9 circulating leukocytes per kilogram but the relative leukocyte count does not exceed 15,000 leukocytes per cubic millimeter. Myeloid immaturity in the peripheral blood does not exceed 1 per cent. In gross leukocytic polycythemia vera, the relative leukocyte count is 15,000 leukocytes per cubic millimeter or more, but myeloid immaturity in peripheral blood does not exceed 1 per cent. In leukemoid polycythemia vera, myeloid immaturity is noted in the peripheral blood in excess of 1 per cent of the differential leukocyte count. Leukocytosis may or may not be present.

TABLE I. LEUKOCYTE VALUES AT INITIAL EXAMINATION AND REMISSIONS AFTER TREATMENT WITH RADIOPHOSPHORUS

Leukocyte Values	Remissions, Per Cent of Cases						Total Cases
	None		Annual or Biennial		3 Years or More		
	Cases	Per Cent	Cases	Per Cent	Cases	Per Cent	
Simple polycythemia vera	12	17.4	25	36.2	32	46.4	69
Occult leukocytic polycythemia vera	12	17.2	39	55.7	19	27.1	70
Gross leukocytic polycythemia vera	20	40.0	24	48.0	6	12.0	50
Leukemoid polycythemia vera	13	52.0	5	20.0	7	28.0	25
Total	57		93		64		214

Remissions

When this classification is applied to a study of the remissions, we note that the rate of failure is the same for both the simple and the occult leukocytic types, but the incidence of long remissions is much higher in the group having simple polycythemia vera (Table I). Failures are progressively greater among patients having gross leukocytosis and even more so if the polycythemia is leukemoid.

It is interesting to note, however, that long

remissions were more frequent in the leukemoid group than in the gross leukocytic group. The leukemoid type seems to be more labile than the gross leukocytic type.

the leukemoid type became and remained relatively simple in type (Table III).

The incidence of chronic leukemoid states is rather low for the simple type, similar for the

TABLE II. LEUKOCYTE VALUES AT INITIAL EXAMINATION AND THE RADIOPHOSPHORUS INDEX IN CASES WITH AT LEAST A ONE-YEAR REMISSION

Initial Type of Polycythemia Vera	Mean P^{32} Index Per Year								Total Cases
	Less Than 3.0 mc.		3.0-5.9 mc.		6.0-8.9 mc.		9.0 mc. and Above		
	Cases	Per Cent	Cases	Per Cent	Cases	Per Cent	Cases	Per Cent	
Simple	43	74.0	12	20.7	1	1.8	2	3.5	58
Occult leukocytic	24	41.5	25	43.0	6	10.3	3	5.2	58
Gross leukocytic	11	38.0	14	48.1	3	10.4	1	3.5	29
Leukemoid	7	53.8	4	30.8	1	7.7	1	7.7	13
Total	85		55		11		7		158

Sensitivity to Radiophosphorus

To measure the patient's sensitivity to radiophosphorus (P^{32}) we employ the radiophosphorus index, which is simply the total amount of radiophosphorus given divided by the total time of treatment (Table II). The result is expressed as millicuries per year. A high percentage of the patients having the simple type of polycythemia vera showed an index of less than 3 mc. per year. In this same index the percentages for occult and gross leukocytic types are almost the same; the percentage is somewhat higher for the leukemoid type, again indicating that leukemoid polycythemia is more labile.

Outcome

The over-all picture of resulting status also shows a definite relation to leukocytic types: 85 per cent of the cases of simple polycythemia vera remained as relatively simple; 62 per cent of the cases which were initially occult leukocytic became and remained relatively simple, while only 44 per cent of the cases of gross leukocytic polycythemia vera and 28 per cent of the cases of occult and gross leukocytic groups, and higher for the leukemoid type of polycythemia vera.

The incidence of acute leukemia is interesting: it is most marked in the occult leukocytic and leukemoid groups (10 to 12 per cent) and low in the gross leukocytic group where this sequela developed in only one case in fifty cases.

In general, these findings are not surprising when one considers that polycythemia vera may involve myeloid elements other than the erythrocytic element. These findings would suggest that the more involvement there is with granulocytic hyperplasia, the higher is the incidence of failure, the higher is the requirement for more radiophosphorus in control, and the greater the chance that either a chronic leukemoid state or acute leukemia will develop.

A partial exception is seen in the gross leukocytic group in which the incidence of acute leukemia is the lowest for any of the groups. In this group, too, it is often difficult to control leukocytosis, although the erythrocytic excess may be controlled. The potential here would seem to be directed largely toward the chronic leukemoid state.

TABLE III. LEUKOCYTE VALUES AT INITIAL EXAMINATION AND ON JANUARY 1, 1956

Leukocyte Values, Initial Examination	Leukocyte Values on January 1, 1956								Total Patients

The Treatment of Scleroderma

R. K. WINKELMANN, M.D.
LOUIS A. BRUNSTING, M.D.
Rochester, Minnesota

When a person resembling a mummy enters a physician's office, the diagnosis probably is scleroderma. Localized scleroderma usually is self-limited and does not endanger life. In the generalized form, vascular changes and homogenization of the connective-tissue collagen pose a therapeutic problem. The authors discuss how to reduce edema and sclerosis and to control the vascular symptoms in this disease.

THE nonsurgical management of certain diseases such as systemic lupus erythematosus, dermatomyositis, and periarteritis nodosa has improved in recent years. The use of steroid compounds and, in the instance of lupus erythematosus, antimalarial drugs has been effective in controlling, if not curing, many of the symptoms of these so-called collagen diseases. Scleroderma usually has been grouped with these pathologic processes; but although some progress in the treatment for this condition has occurred, it has been pedestrian in comparison with the sometimes dramatic symptomatic responses of the other aforementioned diseases to adrenocortical hormonal therapy.

Treatment usually is unsatisfactory in diseases whose etiology is obscure. Because so little is known of the pathologic mechanism of the terrifying mummification of scleroderma, the patients are overly receptive to any active therapeutic attempt and the doctor often is eager to judge favorably any response during a program of therapy. Also, day-to-day variations in edema and other signs of the disease process make it difficult to estimate accurately small changes. These factors account for the large number of therapeutic agents for which effectiveness in scleroderma has been claimed, examples of man's imagination overreaching his capacity for critical thinking.

Forms of Scleroderma

The cornerstone of the therapy of any disease process is the diagnosis. Various forms of sclerosis are organized in the table. Those localized to the skin are quite distinct from progressive systemic sclerosis.

From the Section of Dermatology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Cutaneous.—Linear scleroderma is a developmental cutaneous anomaly and may occupy a dermatome. In the form of hemiatrophy, it may be associated with loss of mesodermal structures localized to one side of the body. In some instances, because of a paramedian location on the scalp and a peculiar atrophic appearance, it is called a "coup de sabre."

TABLE I. CLINICAL FORMS OF SCLERODERMA

Cutaneous
Linear scleroderma
Coup de sabre
Hemiatrophy
Localized and generalized morphea
Systemic
Acrosclerosis (associated with Raynaud's phenomena)
Diffuse scleroderma

Localized morphea, with its violaceous border and ivory-hued sclerotic center, is the most characteristic and frequent form of sclerosis in the skin. Occasionally multiple plaques of this process occur, and for this the term "generalized morphea" has been used. No systemic changes are found.

Systemic.—The association of Raynaud's phenomena with scleroderma has given rise to a clinical variant of the systemic disease, known as "acrosclerosis," in which the skin of the acral regions—the face, the upper part of the chest, the hands and forearms, and occasionally the feet—is principally involved.[1] The onset is insidious; sometimes the Raynaud phase appears as the only sign for years before the development of sclerosis. The process affects women three times as often as men.

Contrasted to acrosclerosis is a form of systemic sclerosis without vasomotor changes which is known as "diffuse scleroderma." In this the skin

has a yellowish, waxy hue and the acral areas, while not completely spared, are only incidentally involved in relation to a major and rapid involvement of the trunk and upper parts of the extremities.[2]

The visceral lesions associated with these systemic types of scleroderma have been reviewed adequately elsewhere.[3-5] Suffice it to say that the principal organs of involvement include the submucosa and muscular layers of the gastrointestinal tract,[6] the interstitial fibrous tissue of the lungs,[7] the myocardium,[8] and more rarely the skeletal muscle and kidneys.

Therapy for Cutaneous Scleroderma

No satisfactory therapy for localized scleroderma is known. It is possible to assure the patient that this process will not endanger life and usually is self-limited. Recently, some success has been gained by use of the antiphlogistic action of antimalarial compounds. No effect may be expected if some response to 250 mg. of chloroquine (aralen) daily is not seen within three months. Routine precautions for the administration of antimalarial agents should be observed.

Therapy for Systemic Scleroderma
(Progressive Systemic Sclerosis)

The treatment of systemic scleroderma is directed toward reduction of the edema and the sclerosis and control of the vasomotor symptoms. By these means it is hoped to restore function of the affected part, for in almost every instance the limitation of function occurs as a consequence of such local conditions. When it is realized that both the obliterative vascular changes and a widespread homogenization of the connective-tissue collagen occur as almost irreversible pathologic processes, the approach to therapy is seen as a formidable challenge.

Maintenance of Circulation.—In acrosclerosis, a major part of the therapeutic effort is directed to increasing the circulation in the extremities and to preventing vasospastic phenomena. To this end a sojourn in a warm climate is often helpful. The patient's environment, wherever he lives, should be maintained at 76° F. or above. Cold must be avoided; housewives must avoid such tasks as hanging out the wash or putting the hands in the refrigerator.

Certain vasodilating agents provide a basic means of controlling vascular spasm. Of these, dibenzyline is the most satisfactory because it can be given orally and because a persistent, adequate effect results in many cases. Ten mg. of dibenzyline three times a day is an adequate beginning dosage. This may then be increased to tolerance or until adequate warming effect is observed. However, it is by no means universally effective and in some instances has to be discontinued because of unpleasant side effects. Other adrenergic blocking agents such as tolazoline and phentolamine have been used, but these have a higher incidence of side reactions on local tissues and have a much shorter effect on vasospasm. The ganglion-blocking agents, tetraethylammonium and hexamethonium, cannot be used except for short periods because of the appreciable systemic effect which they produce in dosages of therapeutic adequacy. Other vasodilating agents, such as nitrites, have been administered systemically as well as by inunction without success. In many instances whiskey by mouth is a satisfactory dilator, acceptable both to the patient and to the physician.

Physical Therapy.—In the effort to reduce sclerosis, physical therapy is extremely important. Together with heat and massage, a graded series of exercises suited to the capability of the part is necessary. Paraffin baths or the heating effect of diathermy or ultrasound may be used. Many observers feel that simple measures such as surface heat combined with activity of the part are sufficient and entail less danger to the skin.

Chelation.—A new method of treatment of scleroderma by chelation has been reported recently by Klein and Harris.[9] This involves the use of edathamil disodium (calcium disodium) versenate by intravenous infusion. Although chelation lowers blood calcium levels, it has become apparent that patients with scleroderma who have no obvious calcium deposit are benefited nevertheless. Our studies with disodium versenate will be reported in detail elsewhere.[10] At present it may be considered that 40 per cent of our cases of acrosclerosis have responded to therapy in a definite and satisfactory way. This includes improvement in esophageal motility as well as measurable functional improvement in the surface tissues.

A total of 50 gm. of disodium versenate is

given intravenously in divided doses based on the patient's weight. Usually, 50 mg. per kilogram of body weight may be given by slow intravenous drip in 5 per cent glucose in water each day. A single intravenous dosage may be 2 to 4 gm. The level of the blood calcium is affected very little by correct therapy, and with slow administration we have had no evidence of low blood calcium in more than 200 infusions. No coagulation defects have been encountered. Tests of daily urine samples are needed for evidence of renal irritation. The only unfavorable side effect to date has been renal tubular irritation with albumin, casts, and cells in the urine. The condition returns to normal after a brief rest period.

Relaxin.—The use of relaxin, a hormone found in the serum of pregnant mammals, for the treatment of scleroderma has been documented by Casten and Boucek.[11] This material was found to control vasomotor phenomena, reduce sclerosis, and help the healing of trophic ulceration; but visceral manifestations were not affected. Because the material is costly and difficult to obtain, various workers have used it only on an experimental basis. Casten and Boucek[11] mentioned that most, if not all, of their patients relapsed in time after the therapy had stopped.

Symptomatic Treatment.—In acrosclerosis, gastrointestinal symptoms such as dysphagia are common. Sometimes dilation is carried out. In event of these difficulties, antacids should be prescribed almost routinely to control reflux esophagitis.[12,13] Elevation of the head of the bed is helpful. Occasionally pancreatic extract is helpful for patients with involvement of the small intestine, even though absorption of material through the wall of the intestines does not seem to be impaired. It is advisable to prescribe supplementary vitamins.

The use of steroids in scleroderma is not to be undertaken without serious deliberation. Usually the arthritic symptoms are relieved, the edema subsides to some extent, and the spirit and appetite improve. This is amply evidenced in the reports of Kierland and Hines.[14,15] Yet continued administration of the steroids is hardly justified for these minor therapeutic results, for in the long run the sclerotic process is not changed by adrenocortical hormone administration. However, in some instances with gastrointestinal involvement, with severe arthritis, or with far-advanced pulmonary changes, it is wise to use small doses of steroids for the beneficial effects they may have upon the patient's sense of well-being and upon the progress of the local process. Doses of triamcinolone (aristocort) in the range of 1 mg. four times a day should be sufficient to gauge the effectiveness of this therapy. Low maintenance dosages should be used. Sometimes it is possible to ease the symptoms of severely sclerosed organs by this means, if it is not possible to prevent their involvement.

Surgical Measures.—Surgical treatment of scleroderma is no longer practiced in a routine manner. Benefit from parathyroidectomy has been reported. Benefit from sympathectomy is limited to the Raynaud's phenomena; the sclerosis is not affected. In the past, some of the good results ascribed to sympathectomy in the treatment of scleroderma have been results of treatment of sclerodactylia consequent to Raynaud's disease rather than true scleroderma.

Prognosis

Patients having slowly progressive insidious acrosclerosis with vasospastic phenomena are given a much better prognosis in respect to survival than those having diffuse systemic sclerosis without vasomotor signs and symptoms. It is apparent, however, that any form of systemic sclerosis may be rapidly progressive; and once the cardiac and respiratory organs are severely involved, the outlook is very grave. Calcinosis of the skin and soft tissues occurs in 25 per cent of cases of acrosclerosis and is limited to this form of the systemic disease. Usually it develops only after about ten years, and only those patients with associated vasomotor phenomena live long enough for calcium deposits to form in the soft tissues.

Summary

The modern treatment of scleroderma has been reviewed. The newest procedure, the use of intravenous chelating agents such as disodium versenate, offers some promise. Vasomotor symptoms, when present, must be controlled by symptomatic treatment. Sclerosis of the hands may be improved by physical therapy. Symptomatic treatment with steroids is only rarely indicated, for steroids will not affect the sclerosis. No completely adequate treatment for, or understanding of, progressive systemic sclerosis exists at the present time.

Obstructive Uropathy in Children

● *Extreme variations in prognosis are often seen to depend as much on diagnostic acumen as on the effectiveness of therapy. The ultimate results obtained are both the credit and responsibility of those in general practice as well as their consultants.*

T. H. SWEETSER, JR., M.D.
Minneapolis, Minnesota

MUCH of the progress in the field of pediatric urology is due to the increased awareness of pediatricians and general practitioners of the high incidence of urinary tract anomalies and disease. Continued advances in technology now admit complete investigation of the urinary tract even in the newborn infant. The benefits of early diagnosis in infants are even more far-reaching and satisfying than in the adult. Especially is this true in the case of obstructive uropathy where often the simplest procedure done early will prevent the gravest complications. Representative cases of various sites and degrees of obstruction serve to illustrate the urgency of early diagnosis.

In Figure 1, one sees the earliest stages of damage resulting from stricture of the urethral meatus, *i.e.*, extreme dilatation of the distal urethra. This was easily corrected by meatotomy. Too often in the past, irreversible damage to the entire urinary tract had occurred before severe symptoms required investigation. In this particular case, the child (a boy, aged two) was noticed to dance around before each voiding and was brought to the family doctor by a slightly embarrassed mother who was as curious as she was concerned. In view of the patient's age it is likely that the stricture was the result of a meatitis following circumcision and repeated irritation of a small but originally adequate meatus. The incidence of similar cases seems high enough to make routine probing of the meatus advisable (both at the time of circumcision and after healing had occurred), as well as doing a simple meatotomy at the time of operation in questionable cases.

Contracture of the vesical neck is less easily diagnosed until complications appear. Often a single bout of unexplained fever, pyuria or merely enuresis is the only finding. Since it is here that the entire upper urinary tract is jeopardized one must be particularly alert. Figures 2 and 3 are examples of irreversible renal and ureteral damage from prolonged obstruction which caused few symptoms until infection intervened. Extensive dilatation and later elongation of the ureters is evident, along with decompensation of the bladder and ureteral orifices with subsequent vesicoureteral reflux. Current therapy, either radical or conservative, is not adequate to cope with this problem at present, but the degree of concern and study should produce some effective treatment in the near future.

At the moment, the only means of preserving renal function is to detect the obstruction before extensive damage has occurred. Proper therapy is completely effective when employed in time.

In Figure 4*a*, one sees the early stages of obstruction at the bladder neck with dilatation of the bladder and beginning hydroureteronephrosis. Figure 4*b* is the essentially normal excretory urogram taken eight weeks after transurethral resection of the vesical neck. This boy's future health was preserved because the referring physician specifically questioned the mother regarding urinary symptoms during a general examination and discovered that the patient had been dribbling small amounts of urine occasionally for about six months between apparently normal voidings.

The occurrence of upper tract damage is much less frequent in girls than in boys, possibly because the former are more prone to develop symptomatic bladder infections earlier in the progress of obstruction and most of these are seen to have bladders which are trebeculated, infected and more or less atonic. The prevalence of urethrotrigonitis in young girls requires the measurement of residual urine to detect the cases of obstruction which often present identical symptoms. Those that have escaped detection in the past and have been carried with repeated courses of chemotherapy often present themselves in later life, with reflux and renal infection finally instigating complete investigation.

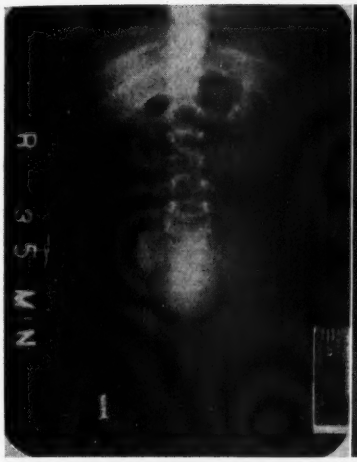

Fig. 1. (J. B.) aged two years. Dancing when urinating. Excretory urograms show stricture of urethral meatus with dilated distal urethra and early dilatation of bladder. Upper tract not yet affected. Results of meatitis following circumcision.

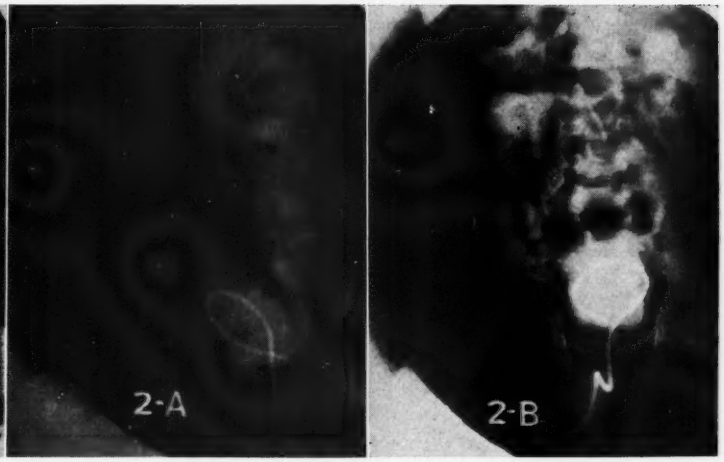

Fig. 2 *a* and *b*. (R. S.) aged two and one-half years. Fever only. Cystograms showed bilateral reflux and marked renal obstruction due to contracted vesical neck. Ultimate prognosis: poor despite operative drainage and correction of obstructive factors.

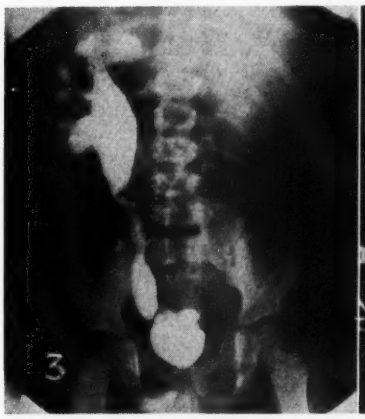

Fig. 3. (D. M.) aged three years. Fever only. Similar case after partial ureterectomy on right still showed reflux which necessitated vesicoureteroplasty; after similar procedure on left patient is improved but still infected. Prognosis: only fair.

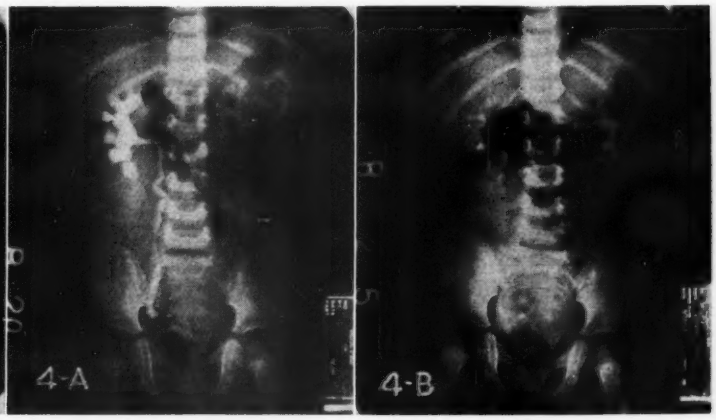

Fig. 4. (M. N.) aged two and one-half years. Occasional urinary dribbling. (*a*) Excretory urogram shows solitary right kidney with early hydroureteronephrosis from distended bladder filling right side of abdomen. Contracted vesical neck corrected by transurethral resection. (b) Eight-week follow-up urogram shows normal upper urinary tract. No residual urine.

This is especially true in cases termed "glomerulonephritis" because of hematuria (with associated albuminuria) preceded by an acute infection elsewhere. The diagnosis of glomerulonephritis can not be assumed until obstructive uropathy is ruled out. Such a case is illustrated in Figure 5, which shows a dilated bladder with reflux to the lower segment of a duplicated right renal pelvis and ureter, secondary to bladder neck obstruction. The duplicated ureters were anastomosed to utilize the better ureter, and a transurethral resection of the bladder neck was done to give a good final result. Presumably earlier diagnosis would have decreased the amount of necessary surgery.

Unilateral ureteral obstruction is often due to ureterocele. Associated with this, one commonly finds duplication of the upper urinary tract. Occasionally prolapse of the ureterocele through the urethra can cause symptoms of intermittent obstruction of the bladder. In each of the illustrated

cases fever was the admitting symptom. In both, extensive studies had been carried out before investigating the urinary tract, since the obstruction was nearly complete and the initial urinalysis had shown only a few pus cells. In the absence of bladder symptoms this obstruction can progress to a marked degree before supervening infection calls for investigation. Adequate resection of the ureterocele, if done early enough, is usually sufficient to restore the obstructed kidney to normal but occasionally sufficient damage has occurred to require nephrectomy. In Figure 6, the latter situation is shown.

Initial resection of the ureterocele permitted catheterization of the obstructed segment and determined the cause of a persistently high fever. The duplication is easily missed on the initial urogram unless one is conscious of the frequency of such an association. Unfortunately, the degree and duration of toxicity in this baby and the presence of ureteropelvic stricture of the lower segment (as well as the dense induration of the ure-

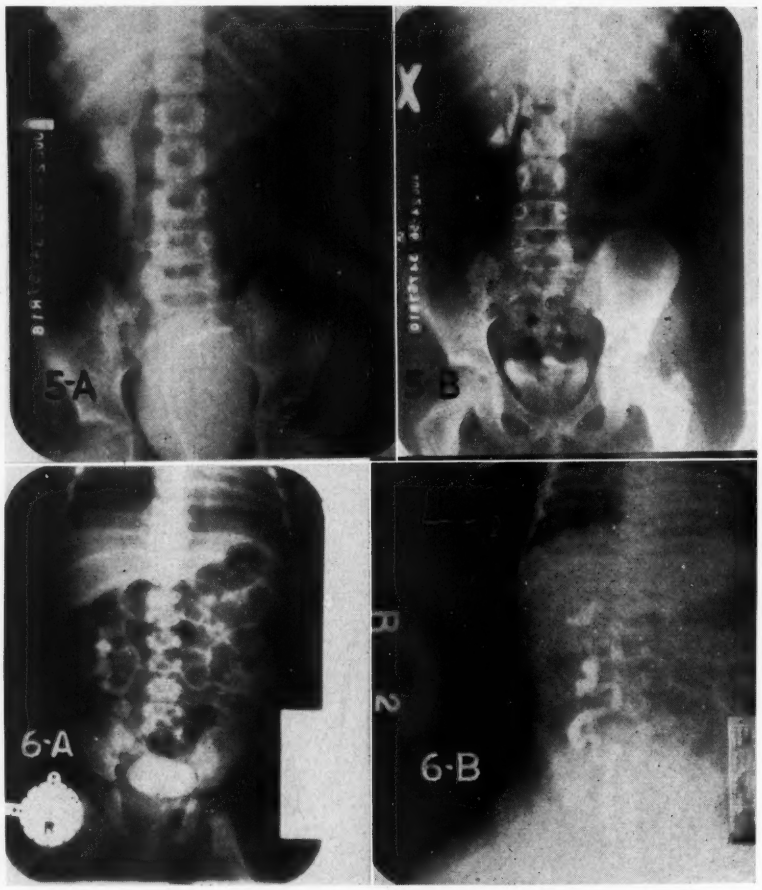

Fig. 5. *(above)* (A. H.) aged six years. Fever, recurrent pyuria and hematuria. *(a)* Cystogram shows dilated bladder with vesicoureteral reflux to lower segment on right due to contracted vesical neck. Ureteral valve to upper segment on right still competent. *(b)* Excretory urogram one year following ureterourecterotomy to utilize good ureter with excision of lower portion of decompensated ureter followed by transurethral resection of vesical neck. Patient asymptomatic and urine sterile.

Fig. 6. *(below)* (M. C.) aged four months. Fever. *(a)* Excretory urogram shows ureterocele and dilated renal calices on right; the latter are due to a congenital ureteropelvic stricture of the lower segment of a completely reduplicated right urinary tract. *(b)* Catheterization of upper segment and ureter following transurethral resection of the ureterocele. Voided urine specimens showed gross pyuria. Catheterized specimens showed only a few pus cells.

ters) did not permit the desired partial nephrectomy and the whole kidney was removed. Reflux up the dilated ureter necessitated later ureterectomy after the patient's condition had improved. She is well at present. In retrospect it is difficult to see how an earlier diagnosis could have been reached to permit less radical therapy but it is always with the greatest reluctance that one sacrifices reparable renal tissue.

Figure 7 shows the rapid restoration of the upper urinary tract in a case where resection of the ureterocele was possible before irreversible damage to the obstructed segment had occurred.

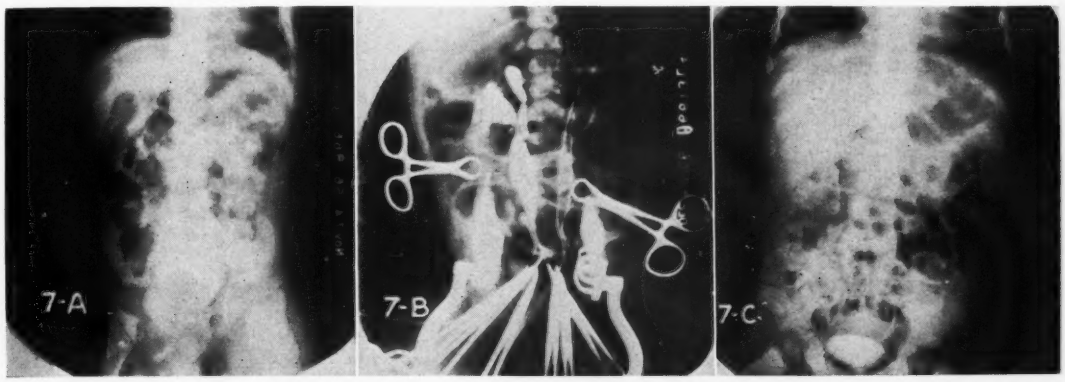

Fig. 7. (R. A.) aged two and one-half years. Recurrent pyuria. *(a)* Large ureterocele did not permit satisfactory endoscopic investigation and resection. *(b)* Suprapubic resection of the ureterocele with catheterization; completely reduplicated upper urinary tracts bilaterally. Ureterocele was associated with upper segment of right kidney. *(c)* Excretory urogram taken eight months later shows essentially normal urinary tract. Urine at present is free of infection.

Fig. 8. (D. L.) aged three years. Recurrent pyuria. Initial retrograde pyelogram shows degree of obstruction that has occurred with few symptoms. Procrastination in this case would have resulted in ultimate loss of the kidney. This patient has responded well to ureteral dilatations and ureteral meatotomy.

Unilateral ureteral obstruction is most commonly due to stricture, usually at the ureterovesical juncture, as illustrated in Figure 8. These respond to cystoscopic dilatations and ureteral meatotomy and such patients have a good prognosis if renal damage is not too extensive. Here again, intermittent bouts of pyuria often permit early diagnosis if adequate investigation is carried out. Hydronephrosis without ureteral obstruction is most often due to ureteropelvic juncture deformity or stricture and a relatively large number of young adults still observed with renal obstruction of various degrees attest to the need for increased awareness of this anomaly in childhood. It has been estimated that between 80 and 85 per cent of uropathy in children and possibly in adults, is due to congenital malformations.[1]

Reports on necropsies performed on children have shown that from 5 to 10 per cent have abnormalities of the genitourinary tract.[2,3] On the basis of existing evidence it is apparent that more thorough investigations of the urinary tract should be made in many instances. Certainly under no circumstances should urinary symptoms of any degree be either blindly treated or ignored.

Use of Intravenous Baird's Solution i agi

● **Uncommon usage of a common anesthetic agent. Good results were reported from this study and the author should make another report when the number of patients is still greater. Anesthesiologists would not recommend this type of obstetrical anesthesia unless administered by an experienced and competent anesthetist who is prepared for intubation and possibly bronchoscopy.**

DURING the period from 1950 to 1954, pentothal sodium with added curare has been used as an induction anesthesia for Cesarean sections at our clinic. After reviewing the literature on this subject, it was decided that a control series of cases in both vaginal deliveries and Cesarean sections should be studied.

Cooley and Schwarz[1] reported the results of 316 maternity cases cared for at Mary's Help Hospital, San Francisco. They used a 2½ per cent solution of pentothal sodium in which the dosage varied from 10 to 40 cc., the average dose being 17 cc. The time interval from the onset of the anesthesia to the time of delivery was a little over three minutes in their cases. The longest time was six minutes and the shortest time one minute. In their studies they believed the following were the advantages of such anesthesia: (1) Induction was rapid and easy, (2) Injection was pleasant, (3) The dosage could be controlled, (4) Recovery was rapid, and (5) It was ideal for patients fearing inhalation anesthesia.

They reported one complication of laryngospasm, and they had one case of postpartum hemorrhage three hours after delivery. Because of the laryngospasm, they routinely gave their patients 1/150 gr. of atropine ten to fifteen minutes before the induction of the anesthesia.

Dippel, Helman, Walters, Wall and Hairston[2] stated that there was no transfer to the fetal circulation of pentothal sodium in the first five minutes of anesthesia; however, there was equal distribution of the anesthetic agent in both the maternal and the fetal circulation at the end of ten minutes. They recommended it should not be used in toxemic patients because the pentothal sodium was destroyed in the liver, and with poor liver function in toxemia, one might get an accumulative effect of the drug. They concluded that the contra-indications for the use of the anesthetic agent were cardiac disease with decompensation, individual idiosyncrasies and toxemia of pregnancy. They used a 2½ per cent solution of pentothal sodium in 350 cases. The dosages varied from 6 cc. to 135 cc. Ninety-one and six-tenths per cent of their cases received a dosage of 10 cc. to 50 cc. Five and four-tenths per cent of their cases received over 50 cc. of the drug. They recommended that pentothal sodium should not be used as a routine anesthetic agent; however, it was relatively safe if the time factors were considered.

In 1938 Kassebohn and Schreiber[3] reported on their use of intravenous anesthesia in obstretrics and they stated that it took forty-five seconds to reach surgical anesthesia with a 5 per cent solution of pentothal sodium. They concluded that there were no ill effects on the infant if delivered within a ten-minute time interval from the onset of the anesthesia.

Schultz and Weinbaum[4] reported 215 cases in which a 2½ per cent solution of pentothal sodium was used. They reported complications of laryngospasm, apnea and patient idiosyncrasies.

Our series of cases consisted of 124 consecutive cases under careful observation and rigid statistical control. We have had approximately 400 cases using pentothal sodium with added curare, however, without the rigid statistical control. Our results in these cases approximate the results in our control group.

n i aginal Deliveries and Cesarean Sections

H. D. CLAPP, M.D.
Crookston, Minnesota

The majority of our patients received Demerol, the dosage varying from 50 mg. to 100 mg. and scopalamine, the dosage varying from 1/300 gr. to 1/150 gr. during the course of their labors. Twenty of the 124 patients received nitrous oxide and oxygen analgesia in the second stage of the labor. The ages of the mothers varied from seventeen to forty-four years, the average being twenty-seven years.

The types of deliveries in the series were as follows: 101 outlet forceps, three modified Scanzoni rotations, two low forceps, eight spontaneous vertex deliveries, three spontaneous breech deliveries and six Cesarean sections.

Of the patients delivered vaginally, thirty-two went into spontaneous labor and eighty-six were electively induced. Active labors varied from one to eighteen hours, the average length of labor being 4.9 hours.

In the six Cesarean sections, two cases indicated central placenta previa, one partial oblatio placenta, one uncontrollable toxemia and two were repeat Cesarean sections.

Pentothal sodium with curare, so-called Baird's solution, was used in these deliveries. The solution was prepared using 15 cc. of a 2 per cent solution of pentothal sodium and adding 5 cc. of D-tubo which contains 15 mg. of curare. The exact amount was recorded on the anesthetic record. The largest total dose was 50 cc. and the smallest 8 cc. The average dose was 13.2 cc. of Baird's solution.

The time interval from the onset of anesthesia to the delivery was accurately recorded on the anesthesia record. This time varied from one minute to seven minutes; the average length of time was 2½ minutes.

In 117 of the 124 cases the infant cried and breathed spontaneously without any type of resuscitation, while seven infants had slight to marked delay in respirations. These cases will be discussed in detail. The baby weights varied from 4 pounds to 9 pounds, 10 ounces.

There were no deleterious effects on the mothers with the use of intravenous Baird's solution. They had good anesthetic effect from the drug with no postanesthesia complications.

Deliveries in which the infants showed some evidence of impaired respirations were as follows:

Case 1.—Para 8, aged thirty-two, admitted to the hospital with painless vaginal bleeding. Examination by x-ray revealed she had a frank breech presentation associated with a central placenta previa. The pregnancy was terminated by a low transverse Cesarean section. The patient received a total of 36 cc. of Baird's solution and there was a two-minute interval from the onset of the anesthetic to the delivery of the infant. The baby did not cry spontaneously; however, respirations were established within one minute. The neonatal course was uneventful.

Case 2.—Para 10, aged thirty-two, was admitted to the hospital for elective induction of labor. The total labor was six and one-half hours with the patient receiving the routine demerol therapy. The pregancy was terminated by delivery of an right occipito-anterior (ORA) vertex presentation by outlet forceps. A total of 12 cc. of Baird's solution was used. The time interval from onset of the anesthetic to the delivery was six minutes. There was less than a one-minute delay in establishing respirations of the infant. The neonatal course was uneventful.

Case 3.—Para 2, aged twenty-one, was admitted to the hospital in active labor. Total labor was three hours associated with moderate to heavy vaginal bleeding in the second stage. The patient received the usual demerol

and scopalamine medication. Delivery was accomplished by outlet forceps of a left occipito-anterior (OLA) presentation. A total of 14 cc. of Baird's solution was used. The time interval from the onset of the anesthetic to delivery was one and one-half minutes. There was approximately a two-minute delay in established respirations. The baby was pale and flaccid at the time of delivery. The placenta showed evidence of a 25 per cent premature separation when examined. The neonatal course was uneventful.

Case 4.—Para 7, aged thirty-three, was admitted to the hospital with painless vaginal bleeding. The diagnosis of central placenta previa was established by x-ray and a sterile pelvic examination was made. The pregnancy was terminated by a low transverse Cesarean section. A total of 36 cc. of Baird's solution was used. There was a five-minute interval between the onset of the anesthetic and delivery of the infant. There was a ten-minute delay in established respirations. Resuscitation was accomplished by pharyngeal aspiration, oxygen and mouth-to-mouth resuscitation. The neonatal course was uneventful.

Case 5.—Para 2, aged twenty-five, was admitted to the hospital and electively induced. Total labor was two hours. The patient received the usual demoral and scopalamine medication. Delivery was accomplished spontaneously of a left sacro-anterior (LSA) frank breech. A total of 17 cc. of Baird's solution was used. There was a seven-minute interval between the onset of the anesthetic and delivery of the infant. Respirations were delayed slightly over one minute, however, the baby responded well to pharyngeal aspiration and oxygen therapy. The neonatal course was uneventful.

Case 6.—Para 0, aged twenty-one, was admitted to the hospital in active labor. The patient had a nine and one-half hour labor under the routine demerol and scopalamine medication. A total of 12 cc. of Baird's solution was used. There was a four and one-half minute interval between the onset of the anesthetic and the delivery of the infant. The pregancy was terminated by low forceps of an OLA vertex presentation. Respirations were delayed slightly over one minute. The neonatal course was uneventful.

Case 7.—Para 2, aged twenty-one, was admitted to the hospital in active labor. There was a total labor of two and one-half hours during which the mother received the routine demerol medication. A total of 12 cc. of Baird's solution was used. Delivery was accomplished spontaneously of a right sacro-anterior (RSA) frank breech presentation. There was a five-minute interval between the onset of the anesthetic and the delivery of the infant. There was approximately a one-minute delay in respirations. The infant was cyanotic at the time of delivery, but responded well to pharyngeal aspiration and oxygen therapy. The neonatal course was uneventful.

Of the 124 infants delivered there was only one neonatal death. This was an erythroblastotic infant who expired during the process of an exchange transfusion approximately two hours after delivery.

Delivery Technique

Our technique is as follows: The patient is placed in a lithotomy position on the delivery table. The perineum is prepared in a routine manner and draped. The patient is catheterized and the obstetrician carries out a vaginal examination before the anesthetic is started. Delivery is not attempted until the operator is convinced that he can deliver the patient within five minutes from the onset of the anesthetic. On some of the patients we have had to use nitrous oxide and oxygen analgesically to keep them comfortable until we could carry out the delivery. Out of 124 cases there were only seven infants which showed any evidence of delayed respirations. We believe that six of these cases were due to obstetrical complications, such as placenta previa, placenta oblatio or toxemia. In only one infant did we feel that the delay was due to the anesthetic agent or to the time interval between the onset of the anesthetic and the delivery of the infant. In reviewing the statistics in this series of 124 cases, we believe that intravenous Baird's solution is an ideal anesthetic agent in selected cases.

Summary

We have reviewed 124 cases in which intravenous Baird's solution has been used in vaginal delivery or Cesarean sections. We have discussed our results, and have compared them with other series of cases. We believe that it is a safe anesthesia when our technique is followed.

Testing Visual Acuity of the Pre-school Child

Visual acuity can be tested at any pre-school age. The techniques are quite simple. The rewards of early detection of acuity defects are measured in terms of a lifetime of preserved vision.

WALTER H. FINK, M.D.
Minneapolis, Minnesota

THE testing of visual acuity in the pre-sccool child constitutes an important phase of visual screening in children. Because of the immaturity of the child's judgment, such tests must be considered approximations. Nevertheless, they are of value in that they serve as indications of visual difficulty and suggest the need for more detailed information.

In this presentation, I wish to consider the tests designed for the various age levels, extending from the newborn to school age. In the newborn and the child a few months old, a visual test may be used to determine roughly the presence or absence of vision. In doing such a test, a small flashlight is used. The flashlight is moved a few feet in front of the baby's eyes and if vision is present, the child is attracted by the light and his eyes will follow it in its movements. Such a test is of limited value, but serves to demonstrate the presence of vision.

In the somewhat older child, the use of small brightly colored objects, such as a rattle, at variable distances attracts the attention and indicates the presence of vision.

In the child from one to two years, the use of a colored marble, rolled on the floor, is very helpful in indicating the presence of vision and the degree. In such a test, the child follows the marble which can be placed at varied distances.

In the two to three-year-old child, the use of familiar objects is useful. Such objects as a safety pin, piece of candy, button, et cetera, held at various distances can be used. One eye should be tested at a time.

In the three to four-year-old child, the use of a circular chart is helpful (Fig. 1). In this method, the child is told to recognize the different positions of the hand which is printed on the chart. This hand is 1/2 inch in height and should be recognized at 15 to 18 feet. Printed directions are given on the reverse side. The best method of testing is

by first familiarizing the child with the test at home under the supervision of the mother. She explains the test to the child and after the child becomes familiar with it, each eye is tested. The mother usually moves backward varying the position of the hand, the child indicating with his hand, the position of the hand on the chart. The importance of the test is not primarily the distance at which the target is recognized, but rather the difference between vision of the eyes tested separately.

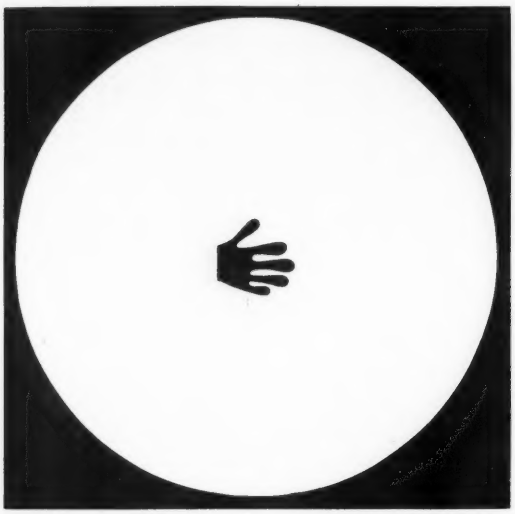

Fig. 1. Circular chart used for testing visual acuity of pre-school children.

For the five to six-year-old child, an illiterate E is substituted for the hand, and the test is carried out similarly to the previous test (Fig. 2).

Fig. 2. Illiterate E chart.

The hand and E tests are done at home. The test is repeated a number of times. The mother keeps record of the results and reports her findings to the doctor, who can then check her findings if any question exists as to the accuracy of her findings.

The five and six-year-old-child can be tested also with a chart on which symbols of various sizes are printed. The chart is attached to the wall at 20 feet with at least fifteen candles of illumination. A piece of cardboard, 6 inches square, with an opening in it is placed over the individual symbols, thus permitting only one symbol to be exposed at a time.

The seven-year-old child may also be tested by using the E symbol, but if he knows the alphabet, the latter method may give more accurate results.

It must be stressed that these tests are approximations and are suggestive. It is also important to point out that the difference in visual acuity between the eyes is as significant as the distance at which the target is recognized.

So frequently the parents of a visually-neglected child accuses the family doctor of having repeatedly ignored the eyes during various routine examinations although the teeth and other phases of the examination are religiously watched. To avoid that criticism, it is my suggestion that the circular chart be passed out to all parents who come to the physician for a routine examination of their child. Because the test is done chiefly by the mother, it takes only a few moments of the doctor's time, and frequently reveals valuable information.

We have, therefore, in the visual acuity a valuable index of the pre-school child's eyes. It is important to stress that the earlier a visual defect is discovered and treated, the better the result because visual development occurs at a very early age and if the defect is not treated until school age, permanent damage is done to the eyes and the child goes through life an ocular cripple.

Psychosis due to Bilateral Carotid Artery Occlusion

• Organic psychosis, if promptly diagnosed and correctly treated, may be followed by dramatic recovery. Unfortunately, the underlying organic disease is too often irreversible. Nevertheless, the clinician should look for organic conditions which could cause sudden disorientation. Presented here is a case of acute psychosis related to the unusual cause of bilateral occlusion of the carotid arteries.

S. K. SHAPIRO, M.D.
Minneapolis, Minnesota

ON THE BASIS of the presenting symptoms, it is frequently difficult to differentiate between the functional and organic causes of a psychosis. The differential diagnosis is possible in many instances by a careful psychiatric and neurological examination but in some patients intensive investigation with special testing is necessary to determine the etiology of a psychosis.

An unusual cause of such a psychosis is presented in the following case report in which the patient presented a psychotic picture which was initially interpreted to be functional in origin and only subsequently was the organic nature of her psychosis appreciated and recognized. Prior to her demise, the presence of unilateral obstruction of the carotid artery was established but only at postmortem was the bilateral nature of her carotid artery obstruction demonstrated.

An excellent review on bilateral carotid obstruction is present in the article by Clarke and Harrison[1] in which the literature on this condition is reviewed and to which the authors have added the cases of two patients of their own. The authors reviewed sixty-nine cases collected from the literature. In 29 per cent of the patients reviewed in the literature, mental changes were encountered. The most common psychiatric picture was that of progressive dementia which was difficult on a clinical basis to distinguish from presenile dementia. Less frequently, hallucinations, delirium and lesser mental symptomatology such as mental slowing and the patient being depressed and languid are encountered. In addition to mental changes, a variety of other neurological abnormalities may be detected with bilateral carotid obstruction. Hemiplegia, paraplegia and quadraplegia have been described with accompanying sensory and visual deficiencies of varying severity. These features are frequently transient and phenomena occurring on one side of the body and then on the other side are characteristic. In the early stage, however, signs may be conspicuously absent and on this account, a "functional" illness may be diagnosed. The resultant clinical picture is dependent upon the efficiency of the collateral circulation and on the speed of the onset of the arterial occlusions. Among the various etiologies reported for this condition are: pulseless disease, atherosclerosis and one case of giant cell arteritis, and such infrequent causes as occlusion of the carotid arteries by large thyroid tumors and thromboangiitis obliterans.

Case Report

Clinical Features and Course.—This woman, aged sixty, was in good health until nine weeks prior to her demise. At that time she became acutely psychotic and a few days later was seen in the office. At the time of her initial examination in the office, the patient was hallucinating and was delusional, stating that people had accused her of marrying her husband for his money. Complete neurological examination at that time was negative. The systolic blood pressure was 250 mm. and the diastolic 145 mm. of Hg.

The patient was admitted to a psychiatric hospital. The electrocardiogram and the blood urea nitrogen determinations were negative as were routine blood and urine studies. After eight electroshock treatments her condition markedly improved and for one week her mental symptoms cleared. However, the patient continued to have feelings of guilt about something she had said while ill. During this entire period there had been fluctuations in her blood pressure with the systolic pressure changing between normal and 200 and corresponding variation of the diastolic pressure. After this one week of being relatively free of mental symptoms, the patient had a relapse. She became confused, and wandered about aimlessly, at times crawling

over the side-rails of her bed. Her hallucinations returned. At this time the patient was seen by an internist, who performed a benzodioxaine test with negative results. He felt that she did not have essential hypertension or a pheochromocytoma. The possibility of a central cause of hypertension was considered. The patient received two more electroshock treatments but there was no improvement in her condition. Following the resumption of electroshock therapy and following the second treatment, it was reported in the afternoon that the patient did not appear to move the left side of her body. The author saw the patient within the hour and could not find any abnormalities and the patient was able to move her left arm and leg freely. The patient gradually became mute and refused to eat and would not get out of bed, although when helped out of bed could walk.

The patient was transferred to Mt. Sinai Hospital (Minneapolis) for further investigation. At this time vascular central nervous system disease and a brain tumor were considered in the differential diagnosis. An angiogram was performed on December 17, 1952 and revealed occlusion of the right internal carotid artery. The patient was conscious following the angiogram and remained that way until following a drop in blood pressure she became comatose and developed a left hemiparesis. Within the next thirteen-hour period the patient developed a dilated right pupil and bilateral Babinski signs. There was weakness of the left arm and leg and some flattening of the left nasolabial fold. On painful stimuli, the left arm and left leg initially moved. The patient developed increasing respiratory difficulty which initially responded to intravenous aminophyllin. Projectile vomiting developed. The pulse became slower and weaker and the pupils were both widely dilated, the right remaining slightly larger than that on the left. Cyanosis developed and terminally, there was a large bloody emesis. The patient succumbed at 4:20 a.m. on December 19, 1952.

Pathological Examination.—The most significant abnormalities in the necropsy were restricted to the carotid arteries and the brain and were reported as follows: The right internal carotid was occluded by an old gray-tan organized thrombus that arose just above the origin of the external carotid branch; this old thrombus extended cephalad for a distance of 2.5 cm. and completely occluded the lumen. Extending proximally there was a softer purplish-red thrombus, undoubtedly retrograde in pathogenesis, which extended for a distance of approximately 6 cm. This completely occluded the lumen, except at its most caudate tip where it ended in a "rat-tail" manner. Another similar purplish-red, rather soft, thrombus extended cephalad from the older thrombus in the right internal carotid artery; this extended the entire course up into the origin of the Circle of Willis where the thrombus extended into the anterior cerebral and middle cerebral arteries on the right.

The left common carotid artery was occluded at its origin from the arch of the aorta by a soft purplish-red thrombus. This extended for a distance of 5 cm., where it could no longer be traced (this may have been more apparent than real, due to partial embalming attempted through both carotid arteries before examination of these branches). There was a similar old organized gray-tan thrombus that completely occluded the lumen of the left internal carotid artery, arising just at the bifurcation and extending for a distance of 2 cm. The external carotid branch was not occluded at this point. No other thrombi were found in the left common carotid artery or its branches.

The vessels at the base of the brain and Circle of Willis showed thrombosis of the right carotid artery, and the right middle and anterior cerebral branches as noted above. The remaining major branches were not grossly thrombosed. The vertebral and basilar artery and Circle of Willis showed only mild to moderate artherosclerosis, but no occlusion.

The pituitary showed an area of necrosis which may have been due to ischemia on the basis of the carotid artery thrombosis. Not all of the pituitary was necrotic.

External examination of the brain showed both cerebral hemispheres to be softened and enlarged with marked flattening of the convolutional pattern, particularly on the right. There was definite tentorial notching and cerebellar conus.

Coronal sections of the entire brain showed diffuse softening of the entire right cerebral hemisphere, most marked in the distribution of the right middle cerebral artery, wherein there was complete softening of the superior half of the internal capsule and softening with hyperemia of the cortex of the greater part of the frontal and parietal lobes. The right occipital pole appeared intact. The left cerebral hemisphere showed suggestive softening in the more central parts but this may have represented poor fixation. Sections of the brain stem showed multiple hemorrhages, particularly in the dorsal half of the mid-brain and upper half of the pons. Sections of cerebellum gave negative findings.

Microscopic.—Sections taken from the right internal carotid artery showed severe atherosclerosis with large plaque causing marked attenuation of the lumen. In addition, there was a fresh thrombus within the remaining lumen. The large plaque showed evidence of an old intramural hematoma which caused the expanding plaque to reduce markedly the size of the original arterial lumen. As a matter of fact, in some sections the lumen and its thrombus occupied a much smaller area than the atheromatous plaque with its old intramural hematoma which contained cholesterin clefts. The external carotid artery on these sections also showed severe atherosclerosis and attenuation of the lumen.

Sections taken from the left internal carotid artery showed similar severe atheromatous plaques attenuating the lumen. The lumen was further occluded in some sections by an antemortem thrombus which was of approximately the same age as the thrombus on the right side, but in which most erythrocytes had undergone hemolysis. The aorta showed moderately severe ulcerating and partially calcified atherosclerosis of the lumbar portion. There were no thrombi.

Microscopic sections of branches of the right internal carotid artery, including the middle and anterior cerebral arteries, showed no thrombus formation. Sections of

the cortex, white matter, basal nuclei and thalamus on the right, showed diffuse and patchy pallor and vacuolization, multiple petechiae and a mild leukocytic response with occasional aggregates of perivascular polymorphonuclear cells. There was no definite macrophage response and the lesion was thus probably less than forty-eight hours old. The sections of similar areas on the left showed less definite evidence of acute encephalomalacia although there was patchy and diffuse pallor and occasional petechiae. Sections of pons showed multiple acute hemorrhages.

Conclusion.—Bilateral thrombosis of the internal carotid arteries with early diffuse malacia of greater part of the right cerebral hemisphere and probably early acute malacia of the left cerebral hemisphere.

Discussion

This patient had evidence of marked chronic obstruction of the bilateral carotid artery systems. Terminally she developed complete obstruction of the carotid artery system with a propagation of the thrombosis on the right to involve the right middle and right anterior cerebral arteries. The dangers of angiography are demonstrated by the rapid downhill course in the patient following this procedure.

Conclusion

A rare case of bilateral occlusion of the carotid arteries is presented. The need for careful differential diagnosis in a patient presenting with a picture of a psychosis is emphasized.

Acknowledgment

The author extends his thanks to Dr. Steven Barron, pathologist, who did the pathological studies on this patient.

Rearmament Not Disarmament

DAVID B. ALLMAN, M.D.
Atlantic City, New Jersey

One international field in which national barriers are conspicuous by their absence and in which agreement exists about the need for rearming with more men and materials is medicine. While we continue to increase and strengthen our world-wide medical armamentarium, we must also strengthen our local medical and *medico-social* armamentaria.

IT IS NOT uncommon for the eyes of medicine to be upon Minnesota and its physicians. For example,

—You are nearing the end of one of the finest state medical meetings I have had the privilege of attending.

—Tomorrow the city of Minneapolis dedicates its new Public Health Center, and I am most happy that I can be present at the ceremonies.

—Next week the World Health Organization opens its Assembly meeting here, and again I am pleased that I can be here for the special tenth anniversary commemorative session of WHO on Monday and Tuesday.

—Then, of course, it is a pleasure to visit Minnesota during your Centennial celebration and to help you re-emphasize the great role medicine has played in the development and growth of this state.

My visit here also allows me to extend to every Minnesota physician a personal invitation to attend the American Medical Association's clinical session here in Minneapolis beginning December 2 and running through December 5 this year.

I particularly want to commend, in advance, the excellent work being done by Dr. O. L. Norman Nelson, general chairman of arrangements for the 1958 clinical session here, and Dr. N. L. Gault, Jr., local chairman of the scientific program. These two gentlemen, I know, are determined to stage the finest AMA clinical session in history, and with your co-operation I have no doubt that they will succeed.

Delivered at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 23, 1958.

Dr. Allman presented this address as President of the American Medical Association.

The AMA session here will be the fifth time the Association has convened in Minnesota. In 1882 and 1901 it met in St. Paul and in 1913 and 1928 in Minneapolis.

Minnesota has always been active in AMA affairs. For example, you have contributed three Presidents—William J. Mayo, Charles W. Mayo, and E. Starr Judd.

And today you have many members in key AMA positions. Ordinarily, when I am at a state meeting, I like to pay tribute to the men and women serving the AMA in various capacities. However, Minnesota has so many physicians on AMA councils and in the House of Delegates that it probably would take at least ten minutes to mention them all.

Nevertheless, let me express my sincere thanks to Minnesota for allowing the AMA to share with you the great talents of these men.

I could continue in this same vein for hours, pointing out the excellent medical contributions of your fine medical school, clinics and hospitals. But you know as well as I do that outstanding medicine is no rarity in America; it is being practiced in New Jersey and the East, the South, the rest of the Midwest and the Far West.

In fact, we know that medicine and good medical work does not belong solely to one state, one region or even one particular country of the world. They are cosmopolitan—they belong to all the world and are at home in any country.

Language, race, money and even government are not insurmountable barriers to good medicine and medical doctors. Medicine itself is a universal language because its procedures—new and old—generally can be equally valuable on every continent.

Medicine is a worldwide profession of mercy, comforting the sick and injured regardless of nationality, creed or color of skin.

Medicine is not a self-seeking profession because the medical benefits to mankind come first before recompense and cost. And even though money sometimes is required to provide facilities, equipment and supplies, unbelievable medical accomplishments have been carried out in many of the most poverty-stricken areas of the world.

Yes, even in communistic and socialistic states medical men strive to benefit the patient despite government intervention, red tape and all the evils of state medicine. Even a government-directed

doctor seeks to improve health and relieve sickness through his medical science, and to ease fear through his art of medicine.

So, I am firmly convinced that medical science is man's true glory, and through its full use around the world we can do more for man's true happiness—peace—than all the gifts and loans of money, and all the demonstrations of military might.

What's more, in medical science there is no Cold War between East and West. We need not go to the summit to seek international inspection systems, for medicine has no secrets. In fact, physicians of the world share their information and are dedicated to the free exchange of all discoveries and new techniques and developments.

Medicine also does not seek a general reduction of physician forces around the world, but rather it favors and promotes *rearmament* of its forces. We seek an adequate medical arsenal of trained and skilled manpower, and all the necessary drugs and instruments to combat and destroy man's greatest enemy—disease.

For example, medical science's tests to develop new atomic techniques will continue—not on the Nevada wastelands or the isolated waters of the Pacific, but in the laboratories of our nation and the world. The objective will not be "clean" bombs or "dirty" bombs to kill man, but *rays* and *ways* to kill the disease that destroys human beings.

All our medical ammunition, however, will be intercontinental in variety, because our war against the fevers of mankind is not limited to one nation or one ideaology. Our aim is the destruction of all mankind's cripplers and killers.

Yes, medicine must be in the *vanguard,* and all our weapons must be ready to intercept the enemy —disease—whenever and wherever it strikes.

We cannot rely solely on "wonder" weapons, either. We need a great corps of men and women to maintain the good health of all peoples and to wage continued war on the outbreaks of disease and injury in all places of the world.

We need more men and women of conscience who constantly seek to do the *right* thing in a *just* way for all human beings, and who are willing to fight mankind's greatest foe day and night.

Thus, the call to medicine around the world must not be *disarmament,* but *rearmament,* for we must bolster our defenses and our offenses with conscientious men and a great armamentarium to assure our nation and the world of less killing by disease and more living because of good medicine.

Here at home we in the medical profession also need to *rearm* ourselves for the growing struggle to keep "medical merchandisers" out of the business of both patient and physician.

Isn't it *disturbing* to you that American doctors are forced to defend this nation's competitive free enterprise system of medical practice—a system that has brought our fellow citizens the highest standards of medical care the world has ever known?

Isn't it disquieting to hear certain medical merchandisers, particularly government, scoff at medicine's achievements, high intentions and good character?

And isn't it *discouraging* to see these outsiders gnawing their way into the field of medicine, medical practice and the doctor-patient relationship, and actually controlling and directing the destinies of physicians and patients?

Disheartening as the situation may be for the free enterprise system and private practice of medicine, the profession and all freedom-loving Americans must not lay down their arms and surrender to government domination or outside dictation.

We in the profession recall with a good deal of pride our successful efforts to fight other legislative attempts in past years to curtail precious freedoms and to bring mediocre medicine to all and good medicine to none.

We remember the great number of allies who came to our support when these groups realized the creeping effects government control of one segment of American life would have on all other segments.

The outlook for our profession and the entire free enterprise system was quite dark less than a decade ago. But a *united effort* returned this nation to sane reasoning. The situation is no less dark now, but again a concerted drive can stop big government from managing the lives of every American.

The doctor who does not think the struggle for the ideals of freedom, personal responsibility, and individual initiative is necessary or worthwhile must be blind, deaf, or both to the dangers.

I realize that it is easy to become preoccupied with our own affairs, to be somewhat unaware of the threats, and to take the easy road of surrendering our responsibilities to others. But let's decide right now that we as physicians will speak up for

freedom and will act in behalf of democracy and the private competitive free enterprise system.

Let's not put ourselves in the position of having to ask ourselves in years to come:

"Where was I and what was I doing when my country and my profession lost their freedom?"

Unfortunately, there has been wide acceptance by legislators and the public of government's role in medical and health affairs. This is because government intrusion into medical services has been labeled "beneficient."

Now, for example, under the guise of social welfare, proposed legislation would provide government-supervised hospitalization and nursing home care for the nation's 15 million persons eligible for Social Security benefits. Without question the proposal has rich political appeal. But without a doubt it offers less than the best medicine.

Making our aged subservient to government with health-care handouts is not the solution to this problem. The solutions lie elsewhere and a vast movement is currently underway to attack the problem with intelligence, enlightened understanding and personal concern.

Some of the most important and respected organizations in the health field are preparing a program which will lead toward a solution of the problem of adequate health care and better health for the aged. These organizations—the American Dental Association, American Hospital Association, American Medical Association, and American Nursing Home Association—have formed the Joint Council to Improve the Health Care of the Aged.

The Joint Council is working in three broad areas, aimed at: (1) reducing the cost of rehabilitation, (2) providing less costly facilities for the aged who are ill, and (3) seeking more widespread coverage of retired workers through the voluntary health insurance industry, which in a few short years has done a phenomenal job of covering some 40 per cent of those over sixty-five years of age.

Basically, this problem of the health care of the aged calls for aggressive leadership of the type you people are equipped to provide, at the community level. Again it will take the *rearming* of our medical forces to get this job done.

For the aged who are chronically ill, we need to look into the establishment of home nursing and home care services, such as have already, in a number of communities, reduced by as much as 60 per cent the need of the community's elderly for hospitalization.

For those who are without adequate means to afford proper health care in acute illness or serious injury, we need to look into the means whereby the state and local welfare departments pay for such emergencies; in many areas, state aid to the indigent is woefully inadequate, and needlessly so.

It is voluntary community leadership that has kept this a vigorous nation. And it is such leadership, now, utilizing to the full our voluntary service agencies and the proven strength of free American institutions, that will bring new hope for our aged before they are legislated into a permanent state of dependency!

Let's make another point clear right now. Everyone of our senior citizens is an extremely important individual. He or she is not just an old man or an old woman. The over-sixty-five person is a distinct personality with hopes, dreams and aspirations just like anyone forty years younger.

Therefore, I am opposed to any federalized system of medical care and hospitalization that would lump these individuals into a mass and reduce them to numbers and nonentities.

We in medicine know the need to treat patients of all ages as important individuals. We see the urgency of strengthening the democratic spirit and the private competitive free enterprise system. We realize the necessity of opposing opportunism that moves too many persons *to get* rather than *to give,* to prefer soft security to militant freedom, and to want the laxness of personal irresponsibility.

Gentlemen, I say to you that if we, and all Americans, do not follow our ideals and fight for them, we soon shall find Big Government sitting squarely in our laps, heavy enough to reduce you and me and every American—young and old—to manageable size.

Only a strengthening of our forces—a rearming if you wish to call it that—will keep government off our backs and will prevent the overthrow of the private, competitive system of medical practice that has placed American medicine in the world spotlight of achievement and advancement and made American medical care the model for all to emulate.

Public Health in Minnesota

An Overview of the Past and a Glance Toward the Future

Dr. Diehl is Senior Vice President for Research and Medical Affairs and Deputy Executive Vice President, American Cancer Society, Inc., New York, N. Y.

The Albert J. Chesley Memorial Lecture of the Minnesota Public Health Conference, Saint Paul, Minnesota, September 18, 1958.

HAROLD S. DIEHL, M.D.
New York, New York

IT is a great honor at any time to be invited to give the Albert J. Chesley Memorial Lecture but to have this privilege during Minnesota centennial year is quite overwhelming. As a matter of fact, when I received the invitation from your program chairman, I replied immediately that I would be pleased and honored to accept but that I doubted my ability to do justice to the occasion.

In this regard, I am much like the man in a small town who was noted far and wide for his forceful and picturesque profanity. On this particular occasion, he was hauling a wagon load of apples to a cider mill in the country. This involved fording a small stream which he did without difficulty but as he was driving up the bank on the far side, the tail-gate of the wagon came open and the apples rolled out and floated downstream. A neighbor seeing this happen, watched in anticipation of a real treat. He was amazed, however, when the driver just got out, stood with his arms akimbo and shook his head as the apples floated away. In disappointment his neighbor called to him and said: "What's the matter? Have you lost your tongue?" "No," he replied, "I just don't feel equal to the occasion."

That is very much the way I feel this evening; but Dr. Chesley and the State of Minnesota both mean so much to me that I will try to share with you some thoughts I have concerning them both in connection with this centennial program. First of all, I would point out that it is most appropriate to speak especially of Dr. Chesley during this centennial year, because he served the State of Minnesota over more than half of the century covered by this centennial celebration.

A hundred years is but a brief moment in the history of the world or even of mankind, but in terms of progress in the prevention and cure of disease, more has been accomplished during this one century than during the millions of years which went before.

This is 1958. In 1858, Minnesota was still a frontier state with a population, exclusive of an unknown number of Indians, of about 170,000, of whom 10,000 lived in Saint Paul; 2,300 in Stillwater; 3,200 in St. Anthony; 2,500 in Minneapolis and 70 in Duluth. The southern part of the state contained a number of villages such as St. Peter, Mankato, Le Sueur and Rochester, but the great areas of the northern and western portions of the state were prairies and forests, the hunting and fishing grounds of Indians and fur traders. Roads were few and travel to the state was primarily by river steamer up the Mississippi.

Minnesota had been advertised in New England as a land of unequalled sunshine and healthful climate, with dry, pure air which gave relief and strength to sufferers from many diseases, but particularly tuberculosis and other diseases of the respiratory tract. One enthusiast wrote, "There has not been one case of sickness in the whole of

Hennepin County for several weeks past. What do you think of that, you who are shaking yourselves to pieces with ague?"

Unfortunately, the records do not confirm these optimistic reports. Living conditions were primitive and sanitation practically non-existent. People suffered greatly from the cold and from malnutrition. Respiratory and intestinal diseases were commonplace, with epidemics of diphtheria, scarlet fever and smallpox frequently taking terrific tolls. Infant mortality was so high that parents of newborn babies merely hoped that their children would survive the hazards of infancy and childhood.

Doctors came into the territory with other settlers but many of them had had little formal or systematic medical training, and some who called themselves "doctor" and cared for the sick had had no medical training whatsoever. Among this group there were, however, two notable exceptions: one, William Worrall Mayo; the other, Charles Nathaniel Hewitt. We will have more to say concerning both of these remarkable men later; but first let us take a look at the status of health and medical care generally at this time.

Almost unbelieveable is the fact that a century ago, the basic concept of micro-organisms as a cause of disease had not been established. The effectiveness of Jenner's vaccine against smallpox had been demonstrated beyond question, and where available and utilized, it provided high grade protection against this disease.

In speaking of Jenner's vaccine, I would digress to explain to those of you who know smallpox vaccination as it is practiced today that in those days, and in fact when I was first vaccinated as a boy, the vaccine most commonly used was made from the macerated crust or scab from someone else's vaccination. When these crusts or scabs from a successful vaccination reached the stage at which they could be removed, physicians carefully preserved them as a source of vaccine for others. Such vaccine material contained not only the virus of cowpox but also various types of pyogenic organisms. The result was that all such vaccinations were infected, in many instances, so badly infected as to produce serious illness and deep vaccination scars that persisted for life.

The studies of Louis Pasteur in France and Robert Koch in Germany, demonstrating beyond doubt that micro-organisms cause disease, and providing the foundation upon which communicable disease control has been developed, were first published in 1876, approximately eighteen years after Minnesota had been granted the status of statehood. Yet more than thirty years earlier, Oliver Wendell Holmes had insisted that childbed fever was an infectious disease carried from one patient to another by the hands of the physician or midwife. A few years later, Semmelweiss in Vienna noted that the death rate from puerperal sepsis was several times as high in the ward of the hospital to which students and physicians came from the dissecting room as it was in other wards of the same hospital. He therefore issued orders that patients were not to be examined by persons coming directly from dissecting rooms. This precaution reduced the mortality from puerperal sepsis from 12 per cent to 3 per cent, and later to approximately 1 per cent.

In surgical operations, a hundred years ago it was accepted that all operative wounds would be infected. In fact, Lord Lister's work which introduced antisepsis into surgical procedures was not begun until 1860 when he was appointed Regius Professor of Systematic Surgery at Glasgow.

The discovery of the causes of tuberculosis, of diphtheria, of typhoid fever, of cholera and other serious epidemic diseases came later. In 1854, cholera, which has been unknown in this country for more than fifty years, killed more than 2,000 people in Chicago in a period of six weeks. In 1866 there was a sizable outbreak of cholera in the Mississippi Valley, and in 1868 the captain of a river boat deposited cholera victims on the levee at Red Wing. The first hospital in Minnesota territory was built in Saint Paul by the Sisters of St. Joseph and was located on the present site of St. Joseph's Hospital. While this hospital was under construction, a cholera epidemic forced the Sisters to open an emergency hospital in Father Galtier's Chapel in Saint Paul. During these early years, malaria prevailed throughout the Mississippi Valley and frequently reached into Minnesota. Yellow fever also occurred from time to time along the Gulf and Atlantic coasts, spreading panic among the population of the cities which it struck. Epidemics of smallpox were frequent and numbered their victims by the thousands.

One could continue at great length with this picture of the conditions of health and of medical knowledge a hundred years ago, but we must get on to the subject of the evening.

An adequate record of the development of public health work in Minnesota over the past century would require volumes and would include the names of hundreds of individuals who have made significant contributions at state and local levels in both voluntary and official health agencies. Anything approaching a complete report of this is obviously impossible in the short time available to me this evening. I have therefore decided to limit my remarks to brief descriptions of a few individuals who made most distinguished contributions to public health on a statewide basis.

Early in my comments, I mentioned the coming to Minnesota in 1854 of Dr. William Worrall Mayo. Not only was Dr. Mayo a pioneer citizen who contributed substantially to the organization and development of the State of Minnesota, including the State Board of Health of which he became a member, but even more important, he gave to Minnesota, the nation and indeed the world, two sons, William J. and Charles H. Mayo, whose names have long been synonymous with the most progressive and highest quality of medical practice. A century ago, no one would have believed it possible that a world-famous center of medical practice, graduate medical education and medical research could be developed at what was then a mere crossroads in southern Minnesota.

Although known primarily as distinguished surgeons and organizers of the renowned Mayo Clinic, both Dr. Will and Dr. Charlie made great contributions to the improvement of the public health. Doubtless the greatest area of this contribution was and continues to be the high standards of medical practice set by the Mayo Clinic, the distinguished research achievements of the Mayo Foundation, and the splendid advanced education and training in clinical medicine given to thousands of physicians by this same institution.

In addition, Dr. Will made a lasting contribution to better health in Minnesota by his support of a strong medical school at the University throughout his thirty-five years of membership on the Board of Regents of the University. Dr. Charlie's service to public health was more direct, in that he served both as health officer of Rochester and as a leader in various statewide health agencies. In both positions, he was a tower of strength for progress in public health—an interest which he maintained until his dying day. So to the Doctors Mayo—the father, William Worrall, and the sons, Dr. Will and Dr. Charlie, we must give great credit for the high quality of both medical and public health services which we enjoy in Minnesota today.

The other distinguished pioneer to whom I referred, was Dr. Charles N. Hewitt. Dr. Hewitt, a well-educated gentleman and a well-qualified physician, came west to Minnesota from New York State after the Civil War, in which he had served as a medical officer with the 50th New York Engineers. Concerning his military service, General Letterman, General Hookers' chief medical officer, said: "He is the best regimental surgeon in the Army of the Potomac."

Upon arriving, Dr. Hewitt settled in Red Wing and devoted himself to the private practice of medicine. However, his training in medicine and in sanitation, and his experience in the Army made him concerned about the lack of an organized public health program in the state. He had read of the establishment of a health department in Massachusetts in 1869, and of a similar action by California two years later. He therefore drafted a bill, modeled after the Massachusetts Act, authorizing a State Board of Health for Minnesota. This bill was supported by the State Medical Society and passed by the Legislature on March 4, 1872, making Minnesota the third state to recognize the health of its citizens as a direct concern of the state government.

Previous legislation authorized various cities, towns and villages to enact ordinances for the control of contagious diseases and the abatement of nuisances. In 1866, the Legislature authorized the township supervisors to become the board of health in the township, a law which, except for minor changes, exists today—ill-adapted though it is to modern health administrative responsibilities.

The law establishing the State Board of Health provided for six physicians appointed by the governor to serve without pay and one as executive secretary at an annual salary of $200. The appropriation to support the work of this board was $500 annually. The first meeting of the Board was held on March 26, 1872, at the time of

a smallpox epidemic in the state in which there were over a thousand cases and about 250 deaths among a total population of 450,000. Diphtheria, scarlet fever and typhoid fever were widespread. The Board of Health, with almost no funds and little public interest, was thus immediately faced with a tremendous task. Dr. A. B. Stuart of Winona was chosen as the first President of this board and Dr. Hewitt was elected Secretary and Executive Officer.

Dr. Hewitt's amazing vision is illustrated by his first report to the Board of Health, in which he stated that, "Disease germs as grains of wheat, must not only be active themselves, but they must find a soil suitable to their development. We deal with disease, therefore, in two ways, first by searching out and destroying the germ, and, second, by preventing the human body, habitations, and so forth, from becoming fit soil for the growth of the germ." This statement was prophetic because it was made several years before the publication of Pasteur's work which demonstrated that micro-organisms are definitely the causative agents of certain communicable diseases.

As a result of Dr. Hewitt's efforts, the Legislature in 1883 passed an act authorizing the State Board of Health to make regulations having the effect of law for the control of communicable diseases. This still maintains and has been of tremendous value over the years in the reduction of communicable diseases in Minnesota.

In 1874, Dr. Hewitt was appointed Professor of Public Health at the University and in 1877 the Regents, upon Dr. Hewitt's recommendation, ruled that every student should have a physical examination upon entrance to the University and annually thereafter. Dr. Hewitt himself conducted many of these examinations and also delivered lectures in public health at the University over a period of twenty-seven years. Both of these activities were truly pioneering, not only in Minnesota but throughout the nation. It is significant also that they formed the basis for the close and effective relationship that has existed ever since between the State Board of Health and the University.

In addition to his administrative and educational activities and responsibilities, Dr. Hewitt continued his interest and his work in the scientific aspects of public health work. In 1890, when his salary was $1,000 per year, at his own expense he spent six weeks in London studying methods of smallpox vaccine production and diphtheria control, and six weeks in Paris becoming acquainted with Pasteur's work in bacteriology and the treatment of rabies.

Returning to Red Wing, he established the first public health laboratories west of the Alleghenies. These laboratories were transferred to a building on the campus of the University in 1893. Also in 1890, having been unable to obtain an adequate supply of smallpox vaccine, Dr. Hewitt began the production of vaccine at his home in Red Wing. This he supplied at cost to health officers and physicians and to the U.S. Army in what was called the Department of Dakota.

In 1895, Dr. Frank Wesbrook, a native of Manitoba, who had had excellent training in bateriology and pathology in England and Germany, was appointed Professor of Bacteriology and Public Health in the Medical School of the University. A little more than a year later, Dr. Hewitt placed the laboratories of the State Board of Health under Dr. Wesbrook's direction. This was followed by the provision of laboratory services for the physicians of the state for the examination of throat cultures for diphtheria bacilli and for Widal tests for typhoid fever. The morphological classification of diphtheria bacilli developed in these laboratories was widely adopted by public health laboratories in this country and in Europe.

In 1897, political considerations led to the termination of Dr. Hewitt's appointment as Secretary and Executive Officer of the Board. He was at this time sixty-one years of age. In his final report to the Board, Dr. Hewitt said, "The best years of my life and effort have gone into this work. I have spared neither time, labor nor thought to make it what it ought to be. Such as it is, the record is made and closed. I resume tomorrow the active practice of my profession with the sincere wish that the public health service of Minnesota may retain and advance the position it has won among similar organizations in other states. I am still anxious that it continue to serve the whole people of Minnesota in the future as in the past." With these words, Dr. Hewitt ended twenty-five years of distinguished leadership and service in public health and Minnesota lost a most extraordinary and devoted public servant.

Successor to Dr. Hewitt as Secretary and

Executive Officer of the State Board of Health was Dr. Henry M. Bracken. Born in Pennsylvania and raised in Ohio where his father practiced medicine, Dr. Bracken started his medical education at the University of Michigan and completed it at the College of Physicians of Columbia University. After graduation from Medical School, Dr. Bracken had a most active and varied career. He first served as surgeon to a mining company in Venezuela; then did graduate work in public health in Edinburgh; served as physician to a boys' school in England; spent three years as doctor for several ships that cruised the Caribbean and South American waters; devoted two years to private medical practice in New England; went to Mexico as a mining camp doctor; returned to New York for further postgraduate study; and in 1885 came to Minnesota and opened an office for the practice of medicine in Minneapolis. In 1887 he was appointed Professor of Materia Medica and Therapeutics in the Medical School. Ten years later he became Secretary and Executive Officer of the State Board of Health.

Dr. Bracken had unusual vision and a strong and forceful character but was reported to have been at times "notably lacking in tact." He built upon the sound foundation laid by Dr. Hewitt, added able members to the staff, and in his twenty-two years of service as Secretary and Executive Officer, substantially expanded and strengthened the work of the State Health Department. In addition, he was one of the organizers of the National Tuberculosis Association, and served both as president and as secretary of the Conference of State and Provincial Health Officers of North America.

Upon Dr. Bracken's resignation in 1919, Dr. Charles E. Smith, Assistant Secretary of the Board, was appointed Secretary and Executive Officer. His tenure in this office, however, was very brief, being terminated by death only two years after his appointment. His successor, appointed in 1921, was Albert J. Chesley, whom this lectureship memorializes and honors.

Dr. Chesley served as Secretary and Executive Officer of the Board from 1921 until his death in 1955, a record tenure of thirty-four years. Long as this is, however, it is twenty years short of Dr. Chesley's complete period of service with the State Board of Health for he started working for the Board as a clerk in 1901 and continued as a part-time laboratory assistant during his years in medical school.

After he completed his medical training he joined the staff of the Board of Health on a full-time basis. His first appointment was as assistant bacteriologist and epidemiologist, but very soon thereafter he was placed in charge of the Division of Epidemiology, a position which he held until his appointment as Secretary and Executive Officer in 1921.

There was only one interruption during Dr. Chesley's forty-eight years of full-time service with the State Board of Health. That was during World War I when, unable to get into the Army, he went to France and later to Poland with the American Red Cross. It was in this latter assignment that I was first privileged to become acquainted with this superb gentleman, friend and public servant.

After the Armistice in November, 1918, Paderewski, President of the New Poland which was reunited after 130 years of partition and domination by Russia, Germany and Austria, requested assistance from the American Red Cross in dealing with the disease, destitution and even starvation of the people of his country which had served as a battleground during four years of war and had endured the repeated passage back and forth of hostile armies. Dr. Chesley immediately volunteered for this service and was given the responsibility of recruiting a staff. Having heard that our University of Minnesota Base Hospital No. 26 was awaiting orders to return to the States, he inquired as to whether any of the group would be interested in joining the mission to Poland. Four of us, all recently graduated from medical school, volunteered and were accepted for this assignment, which proved to be one of the most interesting experiences of our lives.

In the spring of 1919, after obtaining our discharges from the Army and receiving commissions in the American Red Cross, we traveled from Paris to Warsaw on a special train carrying both personnel and supplies. On this same train was the director of laboratories, a woman physician, who went to Poland as Dr. Placida Gardner and returned as Mrs. Chesley. Dr. Chesley had gone to Warsaw ahead of us to make plans and arrangements for our arrival. He was then Chief of Staff and Deputy Commissioner but very soon thereafter was appointed American Red Cross

Commissioner to Poland, in complete charge of the development and operation of the mission.

The medical and health problems of Poland at this time were colossal. Typhus fever, tuberculosis, malaria, dysentery and typhoid fever were everywhere. In 1919 it was estimated that 2,000,000 children in Poland were urgently in need of medical care, of whom 750,000 were orphans; also that 10,000 children died in that one year in Warsaw alone, mostly from tuberculosis. Medical facilities were almost non-existent and medical personnel exceedingly scarce; one physician to 8,000 people overall and one to 15,000 in many areas. And of these physicians, some 400 died from typhus in 1919.

In spite of what appeared to be overwhelming difficulties, Dr. Chesley quietly, patiently and efficiently proceeded to build a large and effective organization. Working with him day and night in offices, in laboratories, and on long trips by train and by automobile to investigate conditions throughout the country, I learned to admire, respect and love this quiet, dedicated and self-effacing man.

Returning to this country in the fall of 1920, Dr. Chesley resumed his position as Director of the Division of Communicable Diseases of the Minnesota Department of Health. Within a year, however, following Dr. Smith's death, Dr. Chesley was appointed Secretary and Executive Officer of the Board. His achievements during the thirty-four years that he held this post are too numerous even to list. However, the almost complete elimination of diphtheria and typhoid fever, the enormous reduction in tuberculosis, as well as in infant and maternal mortality are tangible evidence of his achievements.

Under his administration, the Department of Health greatly expanded its activities, but this was done most conservatively because Dr. Chesley believed that the expenditure of public money is a public trust. I doubt that any state ever received more in public service for the money expended than Minnesota did under Dr. Chesley's administration.

Two of his fundamental concepts for effective public health work were to work co-operatively with the medical profession and with the University and its medical school. Both of these he practiced continuously. As a result he was always able to obtain the support of the State Medical Association for the public health measures which he advocated, and we of the University and its medical school could always count upon his co-operation and support in our efforts to develop educational programs in the field of health for the profession and for the public. In fact he, more than any other one individual, was responsible for the establishment of our now distinguished School of Public Health.

In a recent address, Dr. Gunnar Gunderson, president-elect of the American Medical Association, said:

> "The wise public health physician knows he must lay aside the cloak of authority if he wants to lead. Instead of issuing orders under the law, he endeavors to persuade in order to be an accepted, not an authoritarian, leader." (It Takes Two . . . *J.A.M.A.*, Vol. 166, No. 10, Mar. 8, 1958)

This is the method Dr. Chesley always used. Expressing himself frequently in parables and with a subtle humor, Dr. Chesley carried out most of his administration by suggestion rather than by direction. By this technique he not only obtained cooperation but he encouraged and inspired others to do their best and in so doing, influenced many able young men to devote themselves to careers in public health service. Many of these have attained positions of national leadership. As a matter of fact, some years ago in presenting one of these men to the American Public Health Association as its new president, Dr. Hugh Leavell, Professor of Public Health Administration at Harvard University, said:

> "Dr. Shepard had his professional education in Minnesota, a state that has produced as many leaders in public health for this country as Scotland has for Britain."

On the national scene also, Dr. Chesley was a leader, serving as President of the American Public Health Association, as President and as Secretary-Treasurer of the Conference of State and Provincial Health Officers, as well as in many other prominent and responsible positions. Honors and distinctions, however, meant nothing to him, his only satisfactions coming from doing well the jobs that he believed to be worthwhile.

Over the years, Dr. Chesley had many strong supporters in his work but among these I am sure that he would want me to mention especially Dr. S. Marx White. After graduation from Northwestern University Medical School, Dr.

White decided that Minneapolis was the place that he wanted to live. He turned to internal medicine in which he has had a most distinguished career, serving as Head of the Department of Medicine in our Medical School, and as the President of the American College of Physicians. In spite of his devotion to medicine, Dr. White has given outstanding leadership in the field of public health, including service for many years as a member and as President of the State Board of Health. In this, as well as in other capacities, his friendship, counsel and support were invaluable to Dr. Chesley, in his work, as it has been to me in mine. All of this, Dr. Chesley and I would wish to acknowledge on such an occasion as this.

I mentioned earlier that I traveled from Paris to Warsaw on a train with Dr. Placida Gardner who returned from Poland as Mrs. Chesley.

Their courtship, as you can well imagine, was carried out under very real difficulties. The head of a mission in a foreign country is never "on his own." With his usual resourcefulness, however, Dr. Chesley managed it all so adroitly that their wedding in Warsaw, which I was privileged to attend, came as a complete surprise to almost everyone in the organization. Up to that time, everyone had thought Dr. Chesley a confirmed bachelor. Fortunately, however, for him as well as for all of us who have had Dr. and Mrs. Chesley as intimate and valued friends, Placida proved this idea incorrect. I say "fortunately" because Dr. Chesley could not possibly have had a more understanding and helpful partner throughout his many years as head of our State Department of Health. Much of the credit for his achievements, I am sure, belongs to her. So, Placida, this evening we are honoring and paying tribute to you as well as to him.

And now for a brief glimpse toward the future of public health in Minnesota. When Dr. Chesley was appointed Executive Officer of the State Department of Health, the leading causes of death in Minnesota were pneumonia and influenza, heart disease, cancer and tuberculosis. At the time of his death, the corresponding list consisted of heart disease, cancer, vascular lesions of the central nervous system and accidents.

This change in the "Captains of the Men of Death" suggests the changes of emphasis in public health programs which must be made to adequately meet the public health needs of the future. I say "changes in emphasis" because the measures which have resulted in the control of the serious communicable diseases must not be relaxed. Tuberculosis infection is still widespread and a major cause of illness and disability during early adult years. Even smallpox can become a serious hazard if vaccination is neglected. Grim evidence of this was the epidemic of malignant smallpox in Minnesota in the winter of 1924-25, when there were approximately 1,000 cases and 300 deaths in Minneapolis alone. Diphtheria could again assume epidemic proportions if immunization is neglected. The same is true of typhoid fever and other diseases of the gastrointestinal tract if the sanitary measures which have been so effective in virtually eliminating them are relaxed.

On the other hand, different types of programs are required to deal with heart disease, cancer, accidents, mental illnesses, arthritis, and the other major causes of death and disability today. Dr. Chesley anticipated these changes and adapted the State Health Department programs to meet them.

As I mentioned earlier, two of Dr. Chesley's basic precepts in public health work were effective co-operation with the medical profession and instruction of the public concerning the responsibilities that individuals must assume for their own health and for the health of their families and their communities. These are the types of approach upon which we must primarily depend for progress against the major public health problems of today and of the future.

This being true, we can be assured that as a result of Dr. Chesley's unusual vision and the splendid and devoted staff that he recruited for the State Department of Health, the future of public health in Minnesota will be as bright as the distinguished record of the past.

In conclusion, I would repeat that progress in public health over the century just concluded has far exceeded what even a scientific dreamer could possibly have envisioned a hundred years ago, and that since the establishment of its State Board of Health, Minnesota has been in the forefront of this progress both in this country and abroad.

As to Dr. Chesley's part in all of this, I would quote the inscription which I saw recently above the tomb in St. Paul's Cathedral in London of Sir Christopher Wren, its architect. This inscription reads: *"Si monumentum requiris, circumspice"*—which translated means: "If you would see his monument, look about you."

Medicine: Some Prospects, Challenges, and Opportunities

ROBERT B. HOWARD, M.D.
Minneapolis, Minnesota

THE eminent British historian Arnold Toynbee has described the known civilizations of the world in terms of challenge and response. Those civilizations rising to the greatest heights, those marked by the most significant social, political, esthetic, and technological accomplishments are those which, in Toynbee's view, received the stimulus of a challenge of optimum severity. Those civilizations confronted by challenges too severe, such as an Arctic environment, failed to flourish, since mere survival under such circumstances requires all the energies and talents of the populace, leaving little or none for creative activity.

The effect of a too severe challenge on a civilization could be predicted with reasonable ease. Less predictable perhaps is the opposite side of the Toynbee coin: Those civilizations called upon to meet challenges of less than optimal degree also were characterized by lack of accomplishment. In support of this aspect of his thesis, Toynbee presents numerous examples of "soft" environments failing to spawn significant, productive civilizations.

Toynbee's view of history has, of course, been questioned on many grounds, most prominent among them, perhaps, that it represents a far too sweeping generalization and simplification of a most complex matter. Time and future historians will have to confirm or deny the Toynbee thesis. That it has at least a measure of validity, however, is suggested by our own observations of human behavior, both individual and group. Certainly all of us have seen the challenge-response pattern in our friends, in members of our families, in ourselves. We have noted how frequently in human endeavors the magnitude of the effort evoked seems directly related to the intensity of the challenge presented.

It is our purpose today to examine the challenge, or more correctly, the challenges, that medicine presents to us as students, teachers, practitioners, researchers—challenges which can be translated into opportunities and future prospects. Perhaps such an examination will help us to perceive them more clearly, to act upon them, to be stimulated by them.

Those of you for whom today represents the beginning of your formal medical education are about to meet a challenge probably much greater than any you have faced to date, and it is you whom I want to address particularly, although I hope that my thoughts may have some interest for the others of you as well.

First of all, let me express the hope that you will not look upon the challenge merely in terms of "Can I pass Gross Anatomy?" or "What class rank can I attain?" Such an approach would be a short-sighted one for yourselves, an unhappy one for your patients, and a calamitous one for the future of medicine. Your real challenge during the next four years will be to seize every opportunity offered to you to expand and strengthen your knowledge of the fundamentals of medicine.

You will find that in medical school the emphasis is on *learning* rather than on *teaching*, that you will be presented with almost unlimited opportunities to *learn*, and that you must take advantage of these to the greatest extent possible if you are to fulfill the promise implicit in your being accepted into medical school.

The process of maturing will itself constitute a challenge for you. It will be assumed by the faculty that your outlook is adult, and you will be expected to assume from now on a measure of responsibility for your own education far greater than has been the case so far. In few instances will it suffice simply to know the lecture notes or to have in mind the facts presented in a given text. Rather you will be held responsible for a basic understanding of a subject surpassing factual knowledge alone. You will be held responsible, too, for a standard of personal conduct and appearance becoming a professional person. Your complete, unqualified integrity—undoubtedly

---

Address delivered as the Minneapolis Medical Foundation Lecture on September 29, 1958. Dr. Howard is Dean of the University of Minnesota Medical School.

the physician's single most important and most essential characteristic—will be assumed from the outset. Most sincerely we hope we shall never have cause to question it.

You will be disappointed in many of the things you will *not* learn during your years in medical school. Knowledge in the medical sciences today is extensive and expanding at a rapid rate. To expect you to be finished physicians upon graduations would be unrealistic indeed. Our objectives instead are to give you a sound background in the basic medical sciences, something that few acquire after graduation if they failed to do so during undergraduate years, plus the most thorough knowledge possible of how one approaches a problem in clinical medicine—how information is acquired and synthesized, how a diagnosis is reached, how rational therapy is planned. No attempt will be made to assure your seeing an instance of every known disease or to have you see the "common diseases" in large numbers. To study one patient carefully under competent supervision is worth infinitely more educationally, your faculty believes, than to observe a dozen patients in haphazard fashion.

You will find, too, that we will not spend large amounts of time instructing you in minor technical procedures. Some of you will feel at a disadvantage as you compare your skills of this type with those of graduates of other schools when you begin your internships. I assure you that your good fundamental background will, in the long run, more than make up for any apparent deficiency.

As you can see, our fundamental approach to medical education is based on the concept that it is a lifelong process and that you will continue to be students throughout your professional lives. Certain things we will do our very best to give you during your four years with us; certain other things we will expect you to learn during periods of postgraduate study and training—formal, informal, or both. The M.D. degree, so keenly anticipated at this point in your lives, must ultimately be looked upon as your license to study for the next forty years.

You will find that your teachers feel very strongly their responsibility to you as students of today, but you will learn, too, that in equal measure they feel a responsibility to the student of medicine of the future. To seek new truths, to explore the unexplored, to refine and expand man's knowledge of the human mind and body in health and disease—all of these are goals to which members of your faculty aspire. These are no mere collection of high-sounding platitudes, nor do they represent duties and obligations which pre-empt faculty time that would otherwise be available for teaching, as is sometimes wrongly implied by those who fail to understand the nature of medical education. Rather these objectives constitute an *integral part* of medical education. Without the investigative activity that you will find so characteristic of your school, without this orientation toward the future—combined, of course, with thoughtful concern for the present and proper regard for the past—medicine would indeed be dull and sterile. A trade rather than a profession, it would have little appeal for the imaginative mind.

It will be your challenge to view medicine with imagination and foresight, to perceive the relation between the research you will see going on about you and the medicine you will practice following your years of formal training. Your most effective response to this challenge might well be personal participation in a research project during some phase of your formal education. Opportunities for such participation will be available to you during the coming years. Whether your ultimate goal is the practice of general medicine, specialty practice, or teaching and research, you will find participation in a research project, even if for only a brief period, a richly rewarding experience.

The challenges of medical school will, of course, pale in comparison with those you will meet after you enter practice. The responsibility for the care of a patient is awesome indeed. The knowledge that a life may depend upon your decision or action is truly sobering, an experience quite unparalleled in other human endeavor and a challenge that will bring out the best in the physician of real merit. Yours will be the challenge of putting to the best possible use the fundamental knowledge you acquired in school, of expanding that knowledge, and of blending with it your accumulated experience in such a manner as to bring maximum benefit to your patients.

I have spoken so far of challenges to you as students. Certainly I would be remiss if I failed to point out some of the parallel challenges that face us as members of your faculty. First of all, naturally, is the challenge presented by the young, inquiring minds of a group of carefully selected students such as you. We must stimulate you to

do your very best. More than teaching you, more than making you learn, we must make you *want* to learn. The extent to which we succeed in this will be the measure of our response to this challenge.

Despite our own special areas of interest, we must present to you a unified concept of the clinical approach to medicine, an approach which views the patient as a person, not as a repository for diseased organs. We must instill in you an appreciation for the spirit of inquiry, to which I referred earlier. It is our responsibility to make you see that teaching and research are so inseparably linked in a good medical school that withdrawal of support of either one would produce the ultimate withering of the other.

It is incumbent upon us to assure ourselves that the four short years you spend with us are invested in the most profitable manner possible. We must be alert to the danger inherent in following a certain procedure simply because we have "always done it that way." Tradition can be used to serve our ends, but it can also be a deadly trap. Or to change the metaphor, in listening to the voice of the past, we must accord it careful hearing but not uncritical obeisance. Our lectures, our teaching methods and materials, the curriculum itself deserve frequent review and critical scrutiny. We must not hesitate to eliminate outdated material or to revise courses when circumstances warrant. "Are we doing the best possible job of teaching?" must be a constantly recurring question for all of us.

As members of your faculty, we must strive at all times to establish and maintain the proper relationship of the student to the hospital itself and to members of the staff. In 1912, at the dedication of the Elliott wing of the University Hospitals, Dr. Charles Lyman Greene, Chief of the Medical Clinic, expressed a thought concerning this matter which has equal pertinence today. "It was manifest to us," said Dr. Greene, "as to Flexner, that the student must be a part of the institution and not simply a visitor on sufferance. We must endeavor, therefore, to bring him duly into the closest possible contact with cases and insist that he work out, under proper supervision and control, those problems which belong to the field of actual practice."

Concomitantly, we must fairly and accurately appraise the quality of the student's work. We must recognize the student of outstanding talent and do whatever we can to prepare him for his ultimate role of leadership in medicine. We must be equally alert to the student who does not measure up to our minimum standard, for here our responsibility is not only to our school, ourselves, and the student, but to the community at large, whose members might well suffer at the hands of an inept, insufficiently skilled physician.

I have spoken thus far principally of challenges. What of the prospects and opportunities? I judge that you already see them with reasonable clarity. Your prospects for "success"—however you may wish to measure or define it—are excellent. Like Pip in the Charles Dickens classic, you are people of *Great Expectations.*

Of even more importance, though, are your opportunities. In responding to the challenges outlined, you will be presented with countless opportunities. The opportunity to know and to understand at least something of the structure and function of that most wonderful of Nature's creations, the human body, is an opportunity given to relatively few. It must be respected and cherished and put to use for the benefit of those who place their trust in you.

Beyond this opportunity of knowing that which others know, of understanding that which others understand, lies the opportunity of opening a door in the house of knowledge, allowing light to fall in a room previously blanketed by the darkness of ignorance. The discovery of a truth, even a truth which appears relatively minor in its implications, brings an incomparable thrill.

The concept of service has probably been, for most or all of you, an important motivation for the study of medicine. The opportunity to serve your fellow man in a time of stress will be yours frequently. Such service reaps a rich harvest of satisfaction, of affection, and of respect.

If you can view medicine as a lifelong adventure, which you are now about to begin; if you serve it with all of your skill and ability; if you approach it with all the imaginativeness at your command; then the pleasures you will derive from it will be limitless, the satisfaction unbounded. Your life will be constantly exciting, never hum-drum; and your responsibilities, though heavy, will never be burdensome.

The challenges, the prospects, the opportunities are all yours. Respond to the challenges; rejoice at the prospects; and make the most of the opportunities!

Fractures in Children

General Principles

MALVIN J. NYDAHL, M.D.
Minneapolis, Minnesota

CHILDREN'S FRACTURES are interesting because they are different from adult fractures. Growth alters the picture in children's fractures and because of the physiological factors that occur an intriguing challenge is often presented to the physician. Frequently in studying an x-ray where a bone injury has occurred, particularly in a joint, one is hard-put in deciding what type of fracture or injury the child has sustained. The differential diagnosis in children frequently is much more important than in adults. Various things such as rarefaction produced by blood vessels, congenital fractures, pseudo fractures, dense growth lines, unique pathologic fractures, epiphyseal lines and other phenomena appear on the roentgenogram helping to confuse the issue. Exclusive of transportation and farm accidents, children, in certain age periods, as a general rule, sustain fractures rather relatively easily in the long bones. Adults, too, sustain fractures quite easily as they get older.

We know that under proper care fractures in children usually heal quite readily and we might become a little careless because of this fact. A fracture may terminate disastrously because of indifferent treatment, however. In treating any fracture in a child, the utmost care and diligence should be observed throughout treatment.

When first seeing a child with a possible fracture, every effort should be made to obtain an adequate history. Frequently this is well nigh impossible because of the age of the child and the lack of co-operation. Also, at times, we find that the parents or even playmates are not too helpful in this regard. As in all other conditions in medicine, every effort should be made, however, to obtain an adequate history. Then a thorough and careful examination should be carried out. X-rays should be taken routinely and if there is any question about a fracture or dislocation in a fractured extremity, a comparable x-ray of the normal side should be taken to aid in arriving at the diagnosis.

In treating a fracture every attempt should be made to obtain as anatomical a reduction as possible. However, one should remember if after this attempt has been made and the x-ray does not show anatomical reduction, that a good functional clinical result can be obtained if certain principles are followed. Alignment of the fracture fragments is the chief requirement. If a fracture of the femur has occurred, the alignment of the fracture fragments in relation to the knee joint and the hip should be as accurate as possible. Second, a fracture should not be grossly angulated or rotated. If a rotational deformity is present, it should be corrected in the early stages of treatment and should not be allowed to persist. Marked angulation should be corrected but a slight angulation frequently is compatible with a satisfactory end result. Through experience we have learned that green stick fractures near the center of a long bone, particularly in older children with forearm fractures, must be completely broken through and accurately aligned in order to prevent permanent disability.

There are three local variables which will determine the degree of spontaneous correctibility of angular deformities in long bone fractures of children. First, the age of the child will help in determining the amount of acceptable angular deformity. The nearer the fracture is to the middle of the bone and the older the child, the more accurate the reduction must be. Conversely, the nearer to the end of the bone that the fracture occurs and the younger the child, the more angulation one may accept.

Second, the distance of the fracture from the end of the bone helps determine how much angular deformity one can accept. When the angulation is in the plane of motion of a neighboring ginglymus joint, one can expect a good deal of spontaneous correction of angular deformity. Rotational deformities are permanent. Angulations that are present (other than in the plane of motion of the neighboring joints) are

Dr. Nydahl is Associate Professor, Orthopaedic Surgery, University of Minnesota.

Presented at the Continuation Course in Fractures for General Physicians, University of Minnesota, December 6, 1957.

likely to persist, although they may correct somewhat.

Third, from experience we know that deformities that occur at or near the femoral neck are not corrected by molding. Coxa vara persists and is permanent unless it is corrected by a subtrochanteric osteotomy. Rotational malalignment persists except for minimal physiologic derotation in deformities at or near the femoral neck. Fractures occurring in the proximal femur tend to straighten, however, and for this reason a subtrochanteric osteotomy which is carried out for dislocated hips may have to be repeated because the osteotomy site tends to straighten—thus losing the buttressing effect against the side of the pelvis.

A fracture that has occurred with rotational deformity either externally or internally may be corrected by a rotational osteotomy. As the child gets older, molding of the alignment of the fracture occurs. If angulation at the fracture site is present over a period of months and years in a growing child molding occurs, the general alignment improves and if an x-ray is taken at a later date, it is noted that the molding process has taken place and at times one will have difficulty deciding whether or not a fracture has been present. As we all know this does not occur in adults. For some unexplained reason, a fracture usually stimulates the longitudinal growth of bone in children. This is to be borne in mind in treating fractures of children. Because of this a moderate degree of overriding is acceptable. Fracture fragments that remain side to side in good general alignment will heal without difficulty. Molding will take place over a period of several months and years.

Most fractures in children can be treated by traction or closed manipulative reduction. Conservative treatment should be the standard bearer. Certain fractures in children are operative fractures. Fractures of the neck of the femur which are comparatively rare are considered to be operative fractures. Certain fractures of the elbow joint are operative fractures as follows:

1. Fracture of capitellum with marked displacement.

2. Fracture of trochlea with marked displacement.

3. Fracture of neck of radius with marked angulation of the neck and head of the radius that cannot be reduced by closed manipulative reduction. Open reduction is then indicated. The head of the radius should never be removed in a growing child.

One has to be constantly aware that in children's fractures, possible damage to the epiphyseal line may occur. In the experience of this writer, a sliding type of injury and displacement of the epiphyseal line does not usually result in damage to the epiphysis. A longitudinal or crushing type of injury is the type of injury that is apt to cause disturbance of the epiphysis. This can occur across the entire epiphyseal line resulting in general stoppage or slowing of growth of the involved long bone. A portion of the epiphysis may be injured resulting in stoppage or slowing of the longitudinal bone growth with resulting deformity. The patient and parents should always be advised as to this possible complication. One cannot definitely give an estimate as to the time when this complication might occur. Close clinical observation and x-rays of the involved bones (including the entire bone, together with comparable x-rays of the non-involved bone taken at a distance of six feet at about six-month intervals) will give a fairly accurate estimate as to involvement of the epiphysis. If the measurements reveal that no increase in length has occurred or possibly slight increase in length has occurred, one can then feel that stoppage or slowing of the growth at the epiphysis has not occurred. If there is definite difference in measurements showing that the involved bone is shorter than the normal bone, one then has to feel that there most likely has been damage to the epiphysis. Also after a period of time has elapsed following the injury, x-rays will show if damage to one side of the epiphysis has occurred revealing that the growth line has united. The uninvolved portion of the epiphysis will still be present and if, for instance, this occurs in a knee, genu varus or genu valgus will occur—again depending upon whether the stoppage has occurred on the inner or outer sides.

After a fracture (or fractures) in a child unites, active use of the involved extremity should be encouraged. The carrying of sand bags and pails to improve motion in an elbow is to be condemned. The child is the best guide as to his progress. No attempt should be made to passively manipulate the involved extremity. This will do more damage and frequently will increase the lack of motion in the involved joints. Sometimes it will take months before normal function and motion returns.

Clinical-Pathological Conference

The Minnesota Society
of Clinical Pathologists

CASE PRESENTATION—MINNEAPOLIS VETERANS HOSPITAL

FRANK MORRELL, M.D.
HORACE ZINNEMAN, M.D.
DONALD GLEASON, M.D.

This sixty-year-old white farmer always had considered himself in good health except for "rheumatism" at the age of fifteen. His present illness began in November, 1956, with the insidious onset of weakness, headaches, drowsiness, ataxia, anorexia and a low grade fever. In December, 1956, he was hospitalized at a private hospital. There the physical examination revealed an equivocal Babinski sign on the right, marked ataxia of all four extremities, a positive Rhomberg sign, normal sensation and equal deep tendon reflexes. The right optic disc appeared slightly choked. The spinal fluid was under normal pressure, the total proteins of the fluid were 60 mg. per cent and at a second occasion, 100 mg. per cent. There were 400 white blood cells per cu. mm., glucose was 15 mg. per cent. No pellicle was found; several cultures were negative for acid-fast bacteria and serologic tests for lues were negative. X-rays of the skull were negative and the mastoids showed nothing remarkable. A chest film, intravenous pyelogram, gastrointestinal series and a cholecystogram were negative, as was a right carotid artery angiogram. A bone marrow biopsy was not remarkable. Treatment was begun with streptomycin and isoniazid and shortly thereafter the patient was discharged to his private physician. However, the patient became increasingly confused and his weakness and lethargy increased in spite of the continued antituberculous treatment.

On January 29, 1957, four weeks after the above-mentioned therapeutic regimen had been started, he was admitted to Minneapolis Veterans Administration Hospital. His temperature was 100.6° F., BP 106/62 mm. of Hg. He was drowsy, poorly oriented with a gross memory defect. There was a moderate nuchal rigidity. Both optic discs were hazy, the lung fields were clear to auscultation and percussion. The heart was not enlarged, the rhythm was regular and there was a high-pitched systolic murmur at the left sternal border. The Babinski and Oppenheim signs were positive on the left; the patient was markedly ataxic and the right biceps and patellar reflexes were increased over the left. There was a gross bilateral intention tremor, a tendency to fall to the right, but no sensory impairment was noted.

Laboratory.—Urinalysis was not remarkable at any time. The WBC was 9,450 (65 per cent polymorphonuclear), hemoglobin 14.6 gm./100 ml., sedimentation rate 46 mm./hr., Venereal Disease Research Laboratory (VDRL) and agglutination tests for Brucellae were negative, blood urea nitrogen (BUN) 13.5 mg. per cent. Fasting blood sugar (FBS) 109 mg. per cent. CO_2 25.7 mEq./l., Cl. 97 mEq./l., Na. 133.6 mEq./l., K. 4.3 mEq./l. On admission the spinal fluid was found under an opening pressure of 320 mm. and a closing pressure of 130 mm. H_2O. The total proteins were 156 mg. per cent, sugar 22 mg. per cent, Cl. 118 mEq./l., WBC 97/cu. mm. (65 per cent PMN), cultures for acid-fast bacilli (AFB) and fungi were negative. Complement fixation tests for mumps, Western Equine and St. Louis encephalitis, as well as for lymphocytic choriomeningitis were negative. A chest film showed an infiltrate in the right upper lung field. X-rays of the skull were normal. A ventriculogram was strongly suggestive of an obstruction at the outlet of the 4th ventricle. Skin tests for histoplasmosis, coccidiomycosis, blastomycosis and tuberculosis were negative.

Hospital Course.—The therapy was continued with streptomycin and isoniazid. PAS and Pyridoxin were added to the regimen. A second spinal puncture revealed total proteins of 130 mg. per cent, sugar 5 mg. per cent, only 6 WBC's per cu. mm., all of them lymphocytes. Cultures were again negative for AFB. A concentrate of the spinal fluid failed to show fungi or tumor cells. Gastric aspirations were negative for AFB.

The patient became increasingly lethargic and confused. By February 13 he was no longer able to take oral feedings. Tube feedings were started and cortisone 100 mg. b.i.d. was added to the other medications. On February 21, 1957 the plasma CO_2 had risen to 34.2 mEq./l., the Cl. had dropped to 90 mEq./l. By February 25 these values had changed to 43.2 mEq./l. and 89 mEq./l., respectively. Serum potassium was 2.5 mEq./l. and the BUN 11 mg. per cent. The leukocyte count was 13,900 per cu. mm. (88 per cent PMN), hemogloblin 11.9 gm. per cent. Sedimentation rate was 65 mm./hr.

The cortisone was decreased to 100 mg./day and KCl added to the tube feedings. By March 1 the CO_2 had declined to 34.7 mEq./l. and the serum potassium risen to 3.3 mEq./l. The patient had been comatose since February 13. The blood pressure had been rising slowly to 200/100, and the temperature remained around 102°. On March 19, 1957 Cheyne Stokes breathing was noticed and the patient expired one day later.

Discussion

DR. MORRELL: Trying to piece this story together, we have a sixty-year-old male farmer who has never traveled outside this state and whose illness ran a total course of about four months. It began with vague central nervous system symptoms, headache, a slight fever, and alteration of consciousness. In December 1956 we have the development of an equivocal Babinski sign on the right and ataxia—two focal signs—and a

---

Discussion is by Dr. Frank Morrell, Assistant Professor, Department of Neurology University of Minnesota.

The conference was moderated by Dr. Horace H. Zinneman, Assistant Professor, Department of Medicine, University of Minnesota; Department of Internal Medicine, Veterans Hospital, Minneapolis, Minnesota.

Edited by Dr. Horace H. Zinneman and Dr. Donald Gleason, Chief, Pathology Service, Veterans Hospital.

positive Rhomberg's sign as well. Sensation was normal at that time, and the optic disc was choked. We begin to see the development of focal symptoms as opposed to the generalized symptomatology presented at the onset of the disease. The spinal fluid revealed an elevated protein, 400 white cells per cu. mm., and a depressed sugar level. No pneumoencephalogram had been done, other roentgenograms were negative. The patient was apparently believed to have tuberculous meningitis and was treated with streptomycin and isoniazid.

He was later admitted to this hospital. He still had a very low grade fever and a gross memory defect. He had nuchal rigidity and evidence of meningitic signs. Optic discs were hazy, suggesting perhaps that there was increased intracranial pressure. Now, however, the focal signs—the Babinski and Oppenheim—were on the left and the biceps and patellar reflexes were increased over the left. The signs seem to be shifting, the only consistency being the persistence of ataxia and gross intention tremor. The lack of sensory impairment and cranial nerve signs seemed to me to be particularly significant. They are even more significant when we look at the laboratory findings at the Veterans Hospital. The opening pressure of 320 mm. and a closing pressure of 130 mm. constitute a striking drop. Ordinarily when one finds an opening pressure of 320 mm. one doesn't take out much fluid. If that were true in this case, a closing pressure of 130 mm. would suggest a block of flow at the level of the foramen magnum. In other words, there is a small volume of spinal fluid available under increased pressure and when you take out a small portion there is a much more marked drop in pressure than if there were continuity throughout the ventricular system. This, then, does suggest a block. It seems significant that the clinical findings began with disturbances of consciousness and headache—diffuse signs. They focalized principally in the form of ataxia and perhaps now the development of pyramidal tract findings on the left. How can we put this together? The absence of cranial nerve signs militates against a lesion involving the posterior fossa and encircling the base of the skull such as one might expect in tuberculous meningitis. Ordinarily one would expect some evidence of cranial nerve paresis, some diplopia, sixth nerve palsy, sometimes pupillary changes. The only concrete sign which has localizing value in this case seems to be ataxia, and it suggests involvement of the cerebellar outflow.

There is not a very clear distinction here, between resting postural tremor, head tremor and gross intention tremor. This might have some value inasmuch as we expect intention tremor as the result of hemispheral cerebellar involvement whereas we would expect trunkal tremor from involvement of the cerebellar vermis. We have not yet distinguished between a mass lesion of this cerebellar area and a lesion involving the cerebellar outflow. The shifting signs of pyramidal tract involvement are more likely due to pressure changes within the posterior fossa than to alterations in the cortex. There is no convincing evidence of a lateralized cerebral hemisphere lesion. Anatomically then, our signs point to the posterior fossa and if one also considers the nuchal rigidity and signs of meningitis, to the subarachnoid space. Now may we have x-ray findings?

RADIOLOGIST: The chest x-ray of January shows an infiltrate on the right side. There is a nodular density and another nodule in the lower lung field. The disease appears to be confined entirely to the right lung. We don't have a lateral view to recognize whether the infiltrate is in the upper lobe or the B_8 segment of the lower lobe. It is very likely that all three lobes are involved on the right side. The lesions are non-specific in character. They look more inflammatory than neoplastic from the standpoint of the radiologist. We are dealing then with a relatively chronic disease of the right lung involving multiple lobes. The next is a plain film of the skull, which really gave us no information. The next series of films represents a ventriculogram (Fig. 1) which demonstrates a rather uniform dilatation of the lateral ventricles and to a slightly greater extent the anterior horns. The 3rd ventricle is possibly slightly dilated but could well be within normal limits. And on the last film I think you can see the 4th ventricle, which does not appear to be dilated. This mind, you, is a ventriculogram so that air was introduced through the trephine openings directly into the ventricles.

A film was taken the following day and there was still a great deal of air left in the ventricular system indicating that absorption was reduced. There was no air over the surface of the brain on the twenty-four-hour film. On that basis it was concluded that there was evidence of obstruction at or near the base of the 4th ventricle. Next is the cerebral angiogram (Fig. 2). In the lateral projection the vessels appear to be displaced downward from the skull. If we found this in an individual with a history of head injury the obvious diagnosis would be a sub-dural hematoma. However, in this case the apparent separation is due to some tilting of the head, throwing part of the uninjected half of the brain and skull beyond the injected half.

But as we go on we find that there are findings within the brain itself which are abnormal. You will notice that the anterior cerebral artery is in normal position in the midline with the exception of the basilar portion which appears to be slightly elevated. And the middle cerebral artery appears to be somewhat depressed. This suggests that there may be a mass deep in the brain substance in this area which is displacing the middle cerebral artery downward and slightly laterally. On the venous phase films, there is a vague suggestion of opaque material within the brain substance which does not conform to the normal vascular pattern and which suggests what we normally call "staining." This, however, is very ill-defined and it is really quite questionable.

On summarizing the x-ray findings then, we have a man with a number of pulmonary lesions unilaterally, fibroid in character, and most likely inflammatory in nature. We have evidence of obstruction below the 4th ventricle with a moderate degree of hydrocephalus involving to a minimal degree the 3rd ventricle

Fig. 1. Air ventriculogram showing dilation of lateral ventricles.

Fig. 2. Right cerebral angiogram. See text.

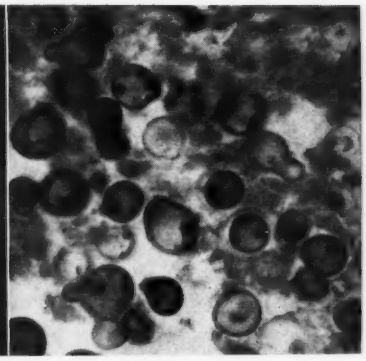

Fig. 3. See text.

and to a rather prominent degree the lateral ventricles. There is evidence to suggest that there is a space occupying lesion in the temporal-frontal area displacing the middle cerebral artery slightly.

DR. MORRELL: I don't think the roentgenologic findings are definitive, with one exception. The 4th ventricle was visualized so that some determination of the site of block could be obtained. We do have evidence, of course, of increased intracranial pressure clinically and by spinal tap. I still think that the bulk of clinical evidence points to a posterior fossa localization involving the cerebellum or cerebellar outflow. Laboratory evidence tends to support this in pointing to the outlet of the 4th ventricle as a site of block. Now then let us attempt to analyze the etiology of this process. We have evidence of low grade fever suggesting an infectious process and a long course suggesting a chronic process. In addition, the leukocyte count in the peripheral blood is not markedly elevated; in fact, not elevated at all in the beginning, and there are no other significant laboratory findings except for the persistently elevated spinal fluid protein and evidence of continued elevation as the disease progresses. The sugar in the spinal fluid remains low. These findings are suggestive of chronic infectious disease involving the meninges and perhaps to some extent the cerebral substance. Spinal fluid cells are fairly low—97 per cu. mm. with a fair predominance of polymorphonuclears. The cultures for acid fast bacteria and for fungi were negative. It might be of interest to know whether any guinea pig inoculations were made of this material.

DR. ZINNEMAN: Only cultures were obtained.

DR. MORRELL: What evidence do we have which will enable us to distinguish what possible infectious process is involved? Most of the fungal diseases and tuberculosis involve a chronic course with a predominance of lymphocytes in the spinal fluid, low grade fever, with increased protein and decreased sugar in the spinal fluid. Most also involve exudative material principally around the base of the brain, and many of the fungi, as you know, are associated with pulmonary involvement as well. Ordinarily, negative skin tests for tuberculosis and for fungi would be highly significant. However, in overwhelming infections one sees negative skin tests. The fact that the patient did not respond at all to streptomycin and isoniazid is somewhat against the presence of tuberculous meningitis. What other kinds of meningitis may be involved? Actinomyces, cryptococcus, and blastomyces are all possible agents. Ordinarily actinomycosis produces a much more acute process with polymorphonuclear spinal fluid reactions and with a pretty frequent incidence of the organism in the spinal fluid. In the others one often has a great deal of difficulty in culture or identification of the organisms. The absence of a pellicle is some argument against tuberculosis but not a great one. I am somewhat impressed with the pulmonary findings as related to the meningitic process. It is, of course, well known that metastatic lesions from lung are common to the brain and the meninges. Meningeal carcinomatosis is known to produce a lymphocytic reaction in the spinal fluid, to produce increased protein in the spinal fluid and a decreased sugar. In a very large proportion of cases there is very often a block and dissemination of tumor cells throughout the fluid. It is also quite common that these cannot be identified on smears. They may be mistaken for large lymphocytes, but no tumor cells were observed in this case. I am not sure whether it is really possible to distinguish between these alternatives—that is, the alternatives of a chronic meningitis—cryptococcosis and blastomycosis are the ones I think of—and a meningeal carcinomatosis. The subsequent course does not help us to distinguish either. Most of the subsequent laboratory findings may very well be due to cortisone therapy. I might ask, by the way, why cortisone was given to this patient. Was it administered to dissolve an exudate?

DR. ZINNEMAN: It was given for that reason.

DR. MORRELL: The terminal findings—the elevation in blood pressure, the Cheyne-Stokes respiration—are fairly easily ascribed to increased pressure and to involvement of the brain stem system by the disease process. One other question which I might raise is whether or not this is simply a chronic infectious process with an exudate around the base of the brain

involving the cerebellar system or whether or not there is a mass in the form of either a metastasis or abscess in the cerebellum to account for the severe ataxia. One argument against an exudate at the base of the brain is the lack of cranial nerve signs. These should be involved fairly early in such processes. I don't think one can still completely rule out tuberculosis, but I will take a chance and suggest that a fungus infection is the better possibility, with the comment that meningeal carcinomatosis with multiple metastases is another alternative.

DR. ZINNEMAN: Thank you very much, Dr. Morrell. Before we hear our discussions, let us have the students' diagnosis.

DR. HAGEN: Six are in. Out of the six, five thought that subacute bacterial endocarditis explained the findings, but one man, thought that this patient had blastomycosis.

DR. ZINNEMAN: Any discussion?

DR. BELL: I was not quite clear how Dr. Morrell explains the ataxia. Will he tell us?

DR. MORRELL: We have no evidence of sensory involvement, but evidence of shifting pyramidal tract involvement and a marked intention tremor involving all extremities. It seems to me that this points to cerebellar involvement, but that, if there was a trunkal ataxia as well, the vermis of the cerebellum, or the cerebellar outflow may be involved.

DR. BELL: Is there any other brain lesion that would cause ataxia other than the cerebellar lesion?

DR. MORRELL: Yes. One sees ataxia in frontal lobe lesions. On the other hand, this is usually associated with pyramidal tract signs. It is very often associated with irritability and psychological disturbances which this patient manifested but which are also quite common with meningitis of any sort. I think that in the absence of a ventricular shift, and absence of any indentation of the lateral ventricle I would suspect that the ataxia was not of frontal lobe origin but much more likely to be cerebellar.

RESIDENT PHYSICIAN: The statement was made in the protocol that the patient tended to fall to the right. Does that help you in the localization of the potential space occupying lesion?

DR. MORRELL: I don't really think so. It is sometimes said that there is a tendency to fall ipsilaterally, but very often one sees falling to either side in cerebellar lesions.

RESIDENT PHYSICIAN: Is the fact that he tends to fall suggestive of a cerebellar lesion?

DR. MORRELL: Yes.

DR. HALL: I would like to know how Dr. Morrell interprets the deviation of the intracerebral vessels.

DR. MORRELL: This would fit with a diagnosis of metastases and I think it is a real possibility. There is not a marked shift, however, and in the presence of fever and other signs of infection I think I would probably put a chronic infectious process first.

DR. HALL: How about the possibility of inflammatory exudates or edema.

DR. MORRELL: I think this is possible for the anterior cerebral deviation. I don't think it is very likely for the depression of the middle cerebral artery.

DR. ZINNEMAN: How did the dura appear to the neurosurgeons when they performed the trephine procedures? There is no report on this item, but I assume that it looked normal.

DR. BELL: You might ask why they didn't give us a biopsy of that dura when they had it out.

DR. ZINNEMAN: I don't know why.

Discussor's Diagnosis

1. Meningitis and pulmonary involvement due to fungi such as Cryptococcus neoformans or Blastomyces dermatitidis.

Clinical Diagnosis

1. Tuberculous meningitis.
2. Pulmonary tuberculosis.

Pathologic Discussion

DR. FINLEY: The body was well developed, well nourished and there were many faded petechia on the abdomen and the anterior surfaces of the arms. In the middle lobe of the right lung there was an area of nodulation measuring 2x3x3 cm. These lesions were firm but not hard. They were nodular and their outlines were fairly distinct. There were a few other indistinct nodulations in the right lower lobe in the B_6 segment but none in the right upper lobe. Sections through these areas revealed areas of greyish-yellow crumbly necrotic material with thin irregular zones of fibrosis around them. There was a thick granulomatous exudate over the base of the brain in the cerebellopontine angle and less extensive patches over the meninges elsewhere. Scattered immediately beneath the exudative areas, particularly in the hippocampus, in the occipital lobe around the calcarine fissure and in the insular gyrus there were small focal areas of necrosis, usually just beneath the surface, in the grey matter. The lateral ventricles were greatly dilated. The third ventricle was slightly dilated. The fourth ventricle was slightly decreased in dimension. It was not dilated. There were focal areas of necrosis in the cerebellum. The largest one was 2 cm. in diameter.

Microscopically, the lesion in the lung showed a solid accumulation of inflammatory and necrotic debris. The alveoli contained some necrotic debris and some acute inflammatory cells but were also extensively filled with the offending organism. The organisms are doubly contoured, oval to round yeast forms, and some of them produce single buds. This is the classic description of blastomycosis (Fig. 3). A periodic acid Schiff-stain shows whole fields filled with blastomyces dermatitidis.

There were multiple scattered abscesses in the brain, in the cerebellum, some in the cortical area of the occipital gyrus, in the calcarine fissue area, in the insular gyrus and in the cerebellar peduncle, and heavy accumulations in the meninges.

Final Anatomical Diagnoses

1. Pulmonary blastomycosis (Blastomyces dermatitidis).
2. Meningeal blastomycosis with cerebral and cerebellar blastomycotic abscesses.

A GOLDEN ERA IN MINNESOTA MEDICAL EDUCATION

A golden era of personal leadership in medical education at the University of Minnesota drew to a close on June 30, 1958. On that date, Dr. Harold S. Diehl left the deanship of the College of Medical Sciences, a post which he had occupied with distinction for more than two decades. Lasting evidences abound testifying to the effectiveness of his service as dean of the state's medical school. These include internationally recognized contributions by the faculty to medical research, national prominence of the school in medical education, and the magnificent physical facilities of the University Medical Center. But to Harold Diehl, the most significant evidence of a medical school's greatness is the quality and professional contributions of its *raison d'etre,* the educated physician graduated from its halls. Thus he could feel an understandable sense of mission accomplished when he surveyed the roster of more than 2,500 physicians who received their M.D. degrees during his administration. Approximately 45 per cent of these, he could reflect, have placed their professional emphasis on the practice of family medicine. He could refer with a pardonable trace of pride to published data which indicate that, for a recent twenty-year period (1930-1949), Minnesota's Medical School joins Harvard as national leader in the number of graduates serving in full-time academic positions on medical school staffs.

The appointment of Dr. Harold S. Diehl to the deanship at Minnesota occurred in 1935. His previous experience had provided an admirably diversified medical, educational, and administrative background for this post of high leadership at the helm of a young and potentially great medical school. This extensive background included study in medicine, pathology, bacteriology, and public health; teaching experience in several fields; military and administrative experience in Europe during and following World War I; direction of the Student Health Service at the University of Minnesota; organization of the University's Department of Preventive Medicine and Public Health; and authorship of several volumes on health for students and the public. Under Doctor Diehl's direction for more than two decades of burgeoning size and prestige in education, research, and service, the College of Medical

HAROLD S. DIEHL, M.D.

Sciences at Minnesota grew to full maturity in the eyes of the people of Minnesota, sister medical schools, universities throughout the world, and the profession to which it contributed.

Doctor Diehl brought to bear a scholarly and carefully reasoned approach to the sweeping problems which confronted him as a medical administrator and educator. His very background as student, instructor, university faculty member, scientific researcher, and author inevitably laid the foundation for a studious, logical attack on any question presented to him.

Yet the viewpoint of this seasoned administrator swept far beyond the purely intellectual. Undoubtedly, a major factor in his effective handling of many a knotty problem was his ability to contribute consistently a multi-faceted approach, the overall view, an invaluable sense of balance of forces and events.

Harold Diehl, for all his administrative genius at the head of a large and complex educational enterprise, will be remembered most dearly by many as the true personal friend and counselor. His gracious, sympathetic, informal manner in associations with his colleagues inspired dedication to the man and to the institution which he led. His sincere, infectious grin and his well-selected humorous anecdotes reduced many a potentially tension-packed administrative issue to a calm, congenial discussion of the pertinent facts available and the possible alternative courses of action. A stranger quickly became a colleague in the councils chaired by Doctor Diehl. His contagious warmth of personality, punctuated by a hearty handshake and that large smile, tended to dissolve reserve and prejudice.

There is a notable exception to the smooth efficiency and rapidity which characterized Doctor Diehl's progress toward a given objective. Anyone who has accompanied him into a meeting hall or to a luncheon table has found progress in this single instance to be exceedingly slow. How can it be otherwise when a man stops as frequently along the way as does "The Dean" to greet and converse with his many friends and colleagues?

The eminent success which Doctor Diehl enjoyed as a medical school administrator was derived in large part from his ability to recognize and gather about him outstanding medical educators and leaders for direction of departments and divisions. Once appointed, a department head could move energetically forward with the assurance that he had the confidence and backing of the administration of the Medical School to develop his area to the fullest. On this basis, Dean Diehl enjoyed excellent rapport with his faculty, which at the same time recognized him completely as the leader and spokesman for the school.

Never one to spare himself from new challenges to serve medical science and the public, Harold Diehl was intrigued with the possibility of continued professional service when, in 1957, the American Cancer Society solicited his vast reservoir of experience and administrative ability for national leadership as Senior Vice President of that organization. Knowing that retirement regulations of the University of Minnesota would, in 1960, bring to a close his long and fruitful career as a medical dean, Doctor Diehl was attracted by the Cancer Society's well-conceived plan to utilize for many years to come his unique capabilities and background in the health sciences. Thus the Medical School's loss of its captain became a distinct gain in the far-flung battle against cancer when the Dean began, late in 1957, to transfer a major portion of his administrative time and effort to New York City.

Those of us who are relatively recent junior colleagues of Dr. Harold S. Diehl consider it a distinct privilege to join the host of his co-workers and friends in a sincere and enthusiastic salute to him and to wish him and his life-long partner, Julia Diehl, the overflowing cup of happiness in their new area of service to medicine and to the nation.

Assistant Dean
College of Medical Sciences
University of Minnesota

ADRENOCORTICAL STEROIDS

The first editorial of this series dealt with the laboratory aspects of these compounds, and now we can review in broad outline some of the indications for the use of the adrenocortical steroids. Probably no other agents have been applied so widely and effectively for so many conditions. Use of these compounds has ranged from their basic application in adrenal deficiency states to the wider field of non-specific anti-inflammatory and anti-allergic effect in conditions such as rheumatoid arthritis and severe asthma. In applying the steroids in our practice, we must always bear in mind that we are using them in many cases to suppress the body's response to inflammation. While this may be rewarding to the patient, potential hazards such as spread of infection must be borne in mind, and such therapy, therefore, represents a calculated risk. The benefits should always be weighed against the risk to the patient, and each case must be judged essentially on its own particular merits.

A medical dictionary defines rheumatoid arthritis as: "a chronic disease of the joints, usually polyarticular, marked by inflammatory changes in the synovial membranes and articular structures and by atrophy and rarefaction of the bones." To our patients, it often means something quite different—incapacity leading to economic stress and finally to collapse of their whole mode of life. Many

This is part two of a four-part editorial.

develop a feeling of hopelessness for the future. In their eyes, therefore, the advent of cortisone was an event of unparalleled importance. As we look back now, we can appreciate their feelings when it became apparent that cortisone could only control to a varying degree the joint manifestations of the disease, and perhaps even then only at the expense of side effects which, even if not dangerous, were unpleasant.

It is in this field of arthritis, therefore, that our newest steroids will be found to have a wide acceptance. Their increased potency offers little in itself, but if one adds to this a reduction in the incidence of side effects, such as edema, then we have truly made a therapeutic advance. Present indications are that these newest steroids do offer these advantages. Opinions are still divided as to the most satisfactory way of commencing corticoid therapy in these patients. Some believe that one should start with a high initial dosage and rapidly reduce it, while others prefer to commence with a minimally effective dosage of the corticosteroid and increase it gradually until an optimum state of clinical control is achieved. Whichever mode of initiation of therapy we prefer individually, we must bear in mind that this represents a round-the-clock addition of corticoids to the system, and in turn leads inevitably to atrophy of the adrenal cortex with resulting suppression of endogenous production of 17-hydroxy-corticoids. These patients, therefore, must be considered in the same light as the Addisonion patient and, if subjected to severe stress, surgery or injury, they require the immediate administration of parenteral hydrocortisone and further careful observation.

A review of the literature shows that certain cases of adrenal insufficiency (Addison's disease or secondary to anteriopituitary corticotropin deficiency) require in addition to cortisone or hydrocortisone, administration of a sodium retainer such as 9-alpha-fluoro-hydrocortisone. The lack of sodium-retaining propensity in our newer steroids, so valuable in the long-term therapy of other conditions, often prohibits their use and always limits their value in this state. They have no established place in the management of true adrenal insufficiency.

In the field of renal disease, the use of steroid therapy has been virtually limited to the treatment of nephrosis. Today, the tendancy to differentiate between adult and childhood nephrosis has all but gone, or indeed, even to separate those patients with so-called "pure nephrosis" from those nephrotic patients who exhibit nephritic signs, such as hematuria and hypertension. A clinical remission of the syndrome occurs when the glomerular permeability to protein returns to normal. This is followed by a rise in serum albumen concentration and a diminution in albuminuria. Since 1950, the adrenocortical steroids have played an increasing rôle in the management of nephrosis. Their administration has often resulted in a prompt diuresis followed by a fairly classical remission. The mechanism of action of the steroids in this respect is still incompletely elucidated. The remissions are often of short duration, and experience would seem to indicate that intermittent therapy with these compounds may be necessary in order to maintain the patient in his initial remission stage. Hyperkalemia has been reported following this therapy, but should be less likely to occur with steroids such as prednisone and prednisolone, and the newer compounds such as methylprednisolone.

JOHN J. PEPPER, M.D.

FEDERAL DAM PLANNERS NEVER CHANGE

Federal dam planners never change. They keep on clamoring in Washington for your tax money to build dams in areas where the people want to take care of their own power needs.

Take the Pacific Northwest today. Investor-owned companies and local agencies are spending close to $1 billion on the largest hydro-electric program to be built at any one time in any sigle area in the history of America.

Local initiative in this area can boast 4.6 million kilowatts of hydro-electric power under construction, just completed or definitely licensed for development. That's as many kilowatts as the Federal Government took a quarter of a century to build in the area—including the huge Coulee, Bonneville and McNary dams.

And the local program is just getting started. Also seriously being considered by the people of the Pacific Northwest are projects designed to produce an additional 4 million kilowatts.

In spite of these magnificent accomplishments, the federal power people keep shouting for more and more taxpayer money for this area—an area which has proven it can take care of its own power needs.

Representative Ben F. Jensen (R-Iowa), ranking minority member of the House Appropriations

Committee, has expressed "deep concern about the proposals of federal power advocates for the expenditure of taxpayer money for the development of our water resources when local interests are willing and able to develop them in a comprehensive manner in keeping with the requirements of law as embodied in the Federal Power Act."

BIRD WATCHING IN THE DOORYARD

When the topic of birds comes up in conversation, I often hear the remark, "We have nothing but Robins and English Sparrows around our yard." I am always sure that remark is a gross understatement, but actually, how many birds is it possible to see around an average dooryard in such locations as Saint Paul and Minneapolis, suburban areas, or in less populated centers throughout the state? I submit that even a cursory check would reveal quite a sizable list.

Since 1942, I have kept a very casual list of birds seen each year. I have made no attempt to set a record or even to keep a complete list. During several years of this period, I have been away from the campus during the summer school or have been engaged in work that made anything like systematic bird watching impossible. No bird was included on my list unless I saw it on the campus and had sufficient opportunity to be certain of my identification. Birds marked with an asterisk (*) are known to have nested on the campus. Others probably were also breeding birds, but no nests were found.

The regular year-around or permanent residents are:

Pheasant*
Screech Owl
Downy Woodpecker*
Hairy Woodpecker
Blue Jay*
Crow*
Chickadee
White-breasted Nuthatch*
English Sparrow*
Starling*
Cardinal*

The occasional winter residents or visitants have been:

Brown Creeper
Cedar Waxwing*
Slate-colored Junco
White-winged Crossbill
Common Redpoll

The list of summer residents and migrants is long. In the first part of the list are those that occur repeatedly in my records. The second part of the list includes those that have been seen only once or twice. The regular migrants and summer residents on the Campus are:

Great Blue Heron
Green Heron
Mallard*
Blue-winged Teal
Lesser Scaup
Sparrow Hawk*
Coot
Killdeer*
Black Tern
Mourning Dove*
Nighthawk*
Chimney Swift*
Hummingbird
Belted Kingfisher
Flicker*
Olive-backed Thrush
Veery*
Eastern Bluebird*
Golden-crowned Kinglet
Ruby-crowned Kinglet
Cedar Waxwing*
Red-eyed Vireo
Warbling Vireo*
Black and White Warbler
Yellow Warbler
Magnolia Warbler
Myrtle Warbler
Chestnut-sided Warbler
Palm Warbler
Ovenbird
Northern Yellow-throat*
Yellow-bellied Sapsucker*
Red-headed Woodpecker*
Eastern Kingbird*
Crested Flycatcher*
Wood Pewee
Phoebe
Tree Swallow*
Bank Swallow
Purple Martin
Brown Creeper
House Wren*
Catbird*
Brown Thrasher*
Robin*
Hermit Thrush
American Redstart
E. Meadowlark*
W. Meadowlark*
Red-winged Blackbird*
Baltimore Oriole*
Bronzed Grackle*
Cowbird*
Scarlet Tanager
Rose-breasted Grosbeak*
Red-eyed Towhee
Goldfinch*
Tree Sparrow
Chipping Sparrow*
White-throated Sparrow
Fox Sparrow
Song Sparrow*

Migrants and summer residents seen only once or twice:

Eared Grebe
Pied-billed Grebe
Black-capped Night Heron
Shoveller Duck
Hooded Merganser
Cooper's Hawk
Bobwhite
Sora
Woodcock
Spotted Sandpiper
Solitary Sandpiper
Yellow-billed Cuckoo
Black-billed Cuckoo
Pileated Woodpecker
Western Kingbird
Wood Thrush
Blue-headed Vireo
Yellow-throated Vireo
Tennessee Warbler
Orange-crowned Warbler
Black-throated Green Warbler
Nashville Warbler
Blackburnian Warbler
Blackpoll Warbler
Northern Water Thrush
Wilson's Warbler
Canada Warbler
Orchard Oriole
Rusty Blackbird
Brewer's Blackbird
Indigo Bunting
Field Sparrow
Savanna Sparrow

The occurrence of some of the water birds on the regular list may seem strange for a residential area in a large city. There is a small lake on the campus which regularly attracts migrating water birds in small numbers, probably wanderers from the main flocks. For the past three years, a pair of Mallards have stopped on the campus. A nest was suspected in 1955 but could not be found. In 1956, a brood of eleven ducklings was hatched. In 1957, after braving the heckling of small boys and their dogs for several weeks, both members of the pair disappeared. Black Tern feed regularly around this lake. At almost any time during the summer lone Blue or Green Herons can be seen in the early morning or toward dusk. A second factor that

may account for some of the other unusual species is an undisturbed wooded area on the campus. Albeit the campus is a favorable spot to observe birds, the number of birds that have been seen is still a fair indicator of the kind of bird watching that is possible without going very far afield.

SISTER ST. MARK WIRTZ, M.S.
The College of St. Catherine

EDUCATIONAL TELEVISION

Adult Education by Television

One of the most pressing concerns of thoughtful students of our society is the question of the continuing education of our people. The American electorate will be called upon to decide questions having to do with numerous, highly technical matters which simply were not known twenty or even ten years ago. A man of forty-two years who graduated from college in 1937, assuming he attended the best possible college, that he was the finest student in the college, and that he was instructed by the finest professors in the world, as a student would still never have heard of atomic fission, penicillin, the Dead Sea scrolls, existentialism, progressive Republicanism or Sputnik II. The names of Dwight, Eisenhower, Adlai Stevenson, Konrad Adenauer, Charles DeGaulle, David Ben-Gurion and Habib Bourguiba would have been almost totally unfamiliar. Space alone forbids the listing of literally thousands of other things, places and concepts which are vital to our progress, thought and perhaps even survival today which were not taught or, for that matter, even speculated upon, a mere twenty years ago. Yet our college graduate of 1937 is now likely to be in a position of considerable influence in our society, a position which will increase in importance as the years go by. He will have to take a part in the momentous decisions of our time. He will be looked to, by those not his equals in age or education, for decisions on these matters about which he was never taught and concerning which he has probably received only the most casual sort of information. This, in a short paragraph, is the central problem of adult, or continuing, education.

Obviously, the press, books, magazines and commercial radio and television can and do fill a part of this educational gap. However, it is equally obvious that all of these media have other and more pressing responsibilities than supplying the need for continuing education. Not the least of these responsibilities is that of making enough money to remain in business. Most of these media, for this and other reasons, cannot stray too far away from popular taste. But study of abstruse scientific and philosophical matters is seldom a "popular" activity. It will not ordinarily appeal to more than 10 per cent of the people, perhaps to even less. No newspaper publisher or commercial television manager can direct his message to so small a group and hope to survive in competition. Yet 10 per cent of our population is seventeen million people, and these are the people who want to know, and who *must* know, the world around them if we are to survive.

Educational television is perhaps the best method yet devised of reaching this 10 per cent who desperately need continuing education. Certainly, it is the least expensive way we have yet devised to inform them of what they want to know. KTCA-TV is a young station, as educational stations go, but in its third month of operation, it could and did provide literally tens of thousands of viewers with the latest and best available information on the history, politics, economics and geography of our enemy, the Soviet Union. This information was given by highly skilled teachers from Hamline University, Macalester College and the Colleges of St. Catherine and St. Thomas. A knowledgeable professor from the University of Minnesota explained, in detail, the nature of our own American government to tens of thousands more. A Nobel prize winer, Dr. Glen Seaborg, instructed thousands in chemistry by his filmed series "The Elements." The National Broadcasting Company made available to all educational television stations a fine live series on mathematics and another on the executive branch of the government, while the function of the engineer in our society was explained by eminent local authorities. And all of this was only a small segment of one week's programming on one educational television station.

No one can know what the full impact of educational television will be on adult education in the years immediately ahead. Only those of limited vision, however, will suggest that its influence will not be very great indeed.

JOHN C. SCHWARZWALDER

LAY VERSUS MEDIC OWNED PUBLICATIONS

Obviously, there are definite differences between medical journals which represent medical organizations and those published by commercial agencies for free distribution. I doubt that the trend toward the use of free distribution periodicals can be

changed. Doctors are overwhelmed with periodicals, and direct-by-mail solicitation through letters, circulars and brochures is becoming too expensive.

The free distribution publications fall into two groups: (1) those which carry general advertising, among which the leaders are *Modern Medicine, MD,* and *Medical Economics,* and (2) those devoted to the interests of an individual pharmaceutical house such as *Scope* (Upjohn), *World-Wide Abstracts of General Medicine* (Warner-Chilcott), *Seminar Report* (Merck), *Spectrum* (Pfizer), *PB* (Lilly), *News* (Ciba), *Therapeutic Notes* (Parke, Davis). Obviously, then, success will depend on the ability of individual editors to make their publications sufficiently attractive or useful to the medical profession to gain the reader's interest and thereby secure his attention.

I am afraid that editors of state medical journals particularly do not have sufficient choice of material that is new and valuable and sufficiently well presented to compete with the free distribution publications which have large budgets sufficient to pay for material that they select which can be published in four colors with innumerable illustrations and which can be kept up to date or even be far in advance of any organizational publication.

Organizational publications moreover, have tended more and more in recent years to be concerned with political affairs, either those of their organization or those related to government. The prolixity and lack of originality and leadership in the latter material has tended to make most medical readers, as far as I can learn, ignore it. More attention is paid to news letters than to the publications.

I have been interested in observing some changes in the circulation of medical periodicals since I discontinued editing of the *Journal of the American Medical Association* in 1950. At that time, the *New England Journal of Medicine* had about 8,000 circulation; it now has 55,000. This is a voluntary subscription publication except for the membership of the New England group. At that time, *Postgraduate Medicine* had 15,000 circulation; it now approximates 40,000 circulation. This is a privately owned voluntary subscription publication with no captive circulation. Apparently, Editors Joseph Garland and Charles Mayo have been able to survive and to progress in the face of competition.

MORRIS FISHBEIN, M.D.

NEW LAW—REGISTER X-RAY APPARATUS

All physicians must register their x-ray apparatus and "tell sources of ionizing radiation" with the Minnesota Board of Health during the month of March. Read details in Public Health section of this issue of the journal.

MEDICAL TECHNOLOGIST OR LABORATORY AID?

Check the following lists and know the difference.

AMA—Approved

1. The Registry (ASCP). Established and incorporated in Colorado in 1928. Operating out of Muncie, Indiana, under the chairmanship of Dr. Lall G. Montgomery of Amer. Society Clinical Path.
2. The American Society of Medical Technologists, ASMT, incorporated in Michigan and functioning since 1933 is official society of registered candidates.
3. "Approved Schools"—approved by the Council on Medical Education and Hospitals of the American Medical Association.
4. Registration examinations prepared and/or edited by members of the Board of Registry (ASCP).
5. Registration insignia for successful candidate: "M.T. (ASCP)."
6. Official Organ: *The American Journal of Medical Technology.*

AMA—Not Approved

1. The American Medical Technologists, AMT. Established in New Jersey about 1940. Operates out of Easthampton, Massachusetts, under the secretaryship of Mr. C. A. Bartholomew.
2. The American College of Medical Technologists, the ACMT, established and incorporated in New Jersey in 1942.
3. "Accredited Schools"— accredited by the Council on Education, Qualifications and Standards of the American College of Medical Technologists, not sanctioned by the AMA.
4. Registry examinations prepared by an "impartial board of qualified examiners," not approved by the AMA.
5. Registration insignia: "M.T."
6. Official Organ: *Journal of American Medical Technologists.*

American Medical Association

Report on Actions of House of Delegates, Twelfth Clinical Meeting

Total attendance at the Twelfth Clinical Meeting of the American Medical Association held in Minneapolis, December 2-5, was 6,072. Included were 3,003 physicians, 664 medical students, nurses, and technicians, and 2,405 guests. A wide variety of issues were considered by the House of Delegates.

Dr. Lonnie A. Coffin of Farmington, Iowa, was named the 1958 General Practitioner of the Year for his outstanding contributions to the health and civic affairs of his home community. Dr. Coffin, who is the first Iowan to receive the annual GP award, accepted his gold medal on behalf of "all the men who have dedicated their lives to the general practice of medicine."

Speaking at the Tuesday opening session of the House, Dr. Gunnar Gundersen of La Crosse, Wisconsin, AMA President, called upon the medical profession to exert leadership and imagination in meeting the problems of these changing times. Urging practical actions to solve medico-economic challenges, Dr. Gundersen declared that "the time has passed for policies based on generalities, platitudes and flag-waving." He also suggested that the Association offer support and co-operation to proposals for an International Medical Year.

Governor Orville L. Freeman, of Minnesota, who also addressed the opening session, asked for "the help of the leaders of the medical profession in working out a program that will most adequately meet the needs of our older citizens for health care and services of the highest quality."

Health Care of the Aged

The House of Delegates adopted the following proposal submitted by the Council on Medical Service and endorsed by the Board of Trustees for help in meeting the health care needs of the aged:

"For persons over sixty-five years of age with reduced incomes and very modest resources, it is necessary immediately to develop further the voluntary health insurance or prepayment plans in a way that would be acceptable both to the recipients and the medical profession. The medical profession must continue to assert its leadership and responsibility for assuring adequate medical care for this group of our citizens.

"Therefore, the Council on Medical Service recommends to the House of Delegates the adoption of the following proposal: That the American Medical Association, the constituent and component medical societies, as well as physicians everywhere, expedite the development of an effective voluntary health insurance or prepayment program for the group over 65 with modest resources or low family income; that physicians agree to accept a level of compensation for medical services rendered to this group which will permit the development of such insurance and prepayment plans at a reduced premium rate."

In order to effect the immediate implementation of such a program, the House directed that copies of the proposal be distributed to medical society approved plans, including Blue Shield and private insurance programs, requesting their co-operation.

Commission on Medical Care Plans

After two hours at a reference committee hearing, the House of Delegates decided to defer action on the report of the Commission on Medical Care Plans until the June 1959 meeting. The delegates adopted this statement:

"We respectfully suggest to the constituent associations reviewing the report in the interim, that their attitude regarding the report will be clarified if they arrive at some decisions in regard to the following basic points:

"1. **Free Choice of Physician.**—Acknowledging the importance of free choice of physician, is this concept to be considered a fundamental principle, incontrovertible, unalterable, and essential to good medical care without qualification?

"2. **Closed Panel Systems.**—What is or will be your attitude regarding physician participation in those systems of medical care which restrict free choice of physician?

"These suggestions acknowledge that the policy of the American Medical Association to encourage and support the highest quality of medical care for all patients remains unchanged. They question, however, whether attitudes toward the free choice of physician and the closed panel system may be undergoing evolutionary change."

The House recommended that the Board of Trustees invite the constituent associations to forward their replies to these questions to the Executive Vice President sixty days in advance of the June, 1959, meeting.

Osteopathy

Considerable discussion centered on a resolution which would have recognized that constituent medical associations have the right to establish the relationship of the medical profession within their respective states. The House decided, however, that the resolution in question did not offer the appropriate solution to the osteopathic problem. Instead, the delegates requested the Judicial Council to review past pronouncements of the House on osteopathy and the status of the laws of the various states in this regard. The Council was asked to present its report and recommendations at the June, 1959, meeting. The House "noted with favor that the American Osteopathic Association has amended its objectives as stated in its constitution by deleting reference to the cultism of Andrew J. Still."

Medical Education

The House approved a statement by the Council on Medical Education and Hospitals supporting the development of additional facilities for basic medical education, and it urged the entire profession to give that policy strong support in order to correct misinterpretations of the Association's viewpoint regarding the supply of physicians.

"American medicine," the statement points out, "fully recognizes the needs being brought about by the increasing population, social and economic trends, and the changing dimensions of medical knowledge and its application." Urging careful analysis of those needs, the statement says that existing medical schools should consider the possibility of increasing their enrollments and developing new facilities. It also declares that American medicine has the responsibility to encourage the creation of new four-year medical schools and two-year basic science programs by institutions of higher education which can provide the desirable setting.

AMA Administrative Structure

A Board of Trustees report on the administrative structure of the Association was approved by the House, which termed the reorganization of the headquarters staff as a long and important step in the right direction. The report informed the House that the Chicago staff has been divided into the following seven divisions: Business Division, Law Division, Communications Division, Field Division, Division of Scientific Publications, Division of Socio-Economic Activities and Division of Scientific Activities. The latter two are still in the process of development and are temporarily under the direction of the Assistant Executive Vice President. The Board also reported that the Committee on Legislation has been renamed the Council on Legislative Activities, with the Director of the Law Division as Council secretary. This new council will undertake an enlarged, strengthened legislative program, closely co-ordinated with the activities of the new field staff and the Washington office. The latter also has been reorganized, with overall direction coming from Chicago.

AMA Objectives and Basic Programs

The House received and commended the report of the Committee to Study AMA Objectives and Basic Programs, which it said may be a significant milepost in the Association's history. In approving one of the committee's recommendations, the House referred to the Council on Constitution and Bylaws the following suggested amendment of Article II of the Constitution:

> "The objectives of the Association are to promote the science and art of medicine and the betterment of public health and an understanding of the socio-economic conditions which will facilitate the attainment of these objectives."

The House also recommended that the Board of Trustees establish a mechanism which will assume the responsibility for promoting active liaison with each medical society. "In the scientific fields," the House declared, "the role of the A.M.A. should be primarily that of leadership, but every endeavor should be made to bring about co-ordination of the special fields of scientific interest of the other national medical organizations." The delegates also approved a recommendation that the Board of Trustees give serious consideration to opening the publications of the Association to a free and open discussion of socio-economic problems applicable to medicine.

Fund Raising

Once again considering fund raising problems which have arisen since development of the concept of united community effort, the House passed a resolution which pointed out that the action taken last June in San Francisco has been interpreted by some as disapproving the inclusion of voluntary health agencies in United Fund drives. It then

stated that the "American Medical Association neither approves nor disapproves of the inclusion of voluntary health agencies in United Fund drives." The resolution also requested the Board of Trustees to arrange a top-level conference with the voluntary health agencies, the United Funds and other parties interested in the raising of funds for health causes, with a view toward resolving misinterpretations and other difficulties in this area.

Miscellaneous Actions

In dealing with a wide variety of other subjects, the House also:

. . Took notice of the recent restrictive changes in the *Medicare* program; expressed regret at the substitution of federal facilities for private care in the areas mentioned, and urged the Association to encourage the re-establishment of services under the free choice principle to accomplish the original intent of the act.

. . Recommended that the Social Security Act be amended by Congress to permit states to combine the present four *Public Assistance* medical programs into a single program, administered by a single agency and making available uniformity of services to all eligible Public Assistance recipients in the state.

. . Authorized the Council on Medical Service to sponsor at the earliest practicable date a *Congress on Prepaid Health Insurance.*

. . Approved a plan to develop *"Buyer's Guides"* which will be sent to physicians to help their patients analyze the merits of available health insurance programs.

. . Approved a Bylaw amendment which will allow *dues exemptions* for interns and residents serving in training programs approved by the Council on Medical Education and Hospitals.

. . Called to the attention of all individuals or institutions responsible for *intern and resident* training that medical services provided to patients in hospitals are the responsibility of duly licensed physicians.

. . Encouraged the voluntary registration of the *paramedical personnel* who assist physicians, but opposed the extension of governmental licensure and governmental registration at this time.

. . Heartily approved and lauded the purpose, content and format of *The AMA News* and recommended continuance of the publication under its present and established policies.

. . Agreed with the Committee on Medical Practices that *relative value studies* should be conducted by each constituent medical association but not on a national or regional basis by the AMA.

. . Urged each constituent society to establish a committee on *rehabilitation* to carry out activities recommended by the Board of Trustees.

. . Called for continued activity at all levels to stimulate the development of effective *poliomyelitis inoculation programs.*

. . Suggested that the Association take immediate steps toward developing a plan whereby reserve medical units and individuals not immediately involved in military operations could be used to supplement *civil defense operations.*

. . Expressed gratitude and appreciation for the long years of devoted service by *Dr. Austin Smith,* who has resigned as Editor of *The Journal of the American Medical Association.*

At the opening session, six state medical societies contributed a total of almost $250,000 to the American Medical Education Foundation. The gifts were: California, $150,305.75; Indiana, $35,110; New Jersey, $25.000; New York, $19,608; Utah, $9,977.50 and Arizona $8,657.50. In addition, the American Medical Association announced a contribution of $100,000 to the Foundation.

"GOOD HEALTH" IN 1959

The year 1958, now in its twilight hours, brought no startling discoveries in the world of medicine. But during the year there was remarkable progress in vital fields of research and practice.

Important scientific advancement was recorded in space medicine and mental health, and in the fight against diabetes, staphylococci, cancer, and heart diseases, to name a few. And while this progress is not dramatic in itself, it brought researchers nearer discoveries that undoubtedly will prove to be major breakthroughs in the months or years ahead.

A peek into the future, however, indicates that 1959 could be a banner year as far as the health of the nation is concerned. Steps already have been taken to solve the problems rising out of a growing old-age population. And the new year also will see increased activity in medical research, particularly in the study of heart diseases, chronic ailments, and cancer.

The dawn of a new year always brings new hopes to the suffering and new inspiration to the scientists and practitioners. It is the prayer of all that the traditional new year's wish of "good health" will have a real meaning to many before 1959 becomes history. —*AMA News*

President's Letter

FORWARD GLANCES—1959

Dr. Carl Drake of Saint Paul was chosen the 1959 President-Elect of the Minnesota State Medical Association by the House of Delegates at the 1958 annual meeting of the Association in Minneapolis. Shortly thereafter, however, Dr. Drake became ill and he subsequently resigned from his office in the best interests of his health. This resignation was regretfully accepted by the Council, and best wishes were extended to Dr. Drake. Dr. Drake served as editor of MINNESOTA MEDICINE for many years, and would have been an excellent president. We hope that he will be well again soon.

At the October meeting of the Council, in accordance with the Association's by-laws, the Council named me to succeed Dr. Drake. The Council perhaps considered that after I had served more than twenty years as the Association's secretary, it was time for me to move on or out. At any rate, I am quite proud to have been chosen to be your next president. At the same time, I feel rather humble in accepting the office with all its many responsibilities. However, God be willing, I shall endeavor to uphold the stature and dignity of the Association to the best of my ability.

And now that I am in, I find that "time and tide waits for no man" and one of the first exacting duties I have to perform is to write the so-called President's Letter for January with the "dead-line" near at hand. Beginning a new year, therefore, I wish to extend the season's greetings to members of the Minnesota State Medical Association and the many readers of MINNESOTA MEDICINE, and I hope all will have a happy and prosperous 1959.

The year 1958 was a busy one with the many events and meetings, particularly in keeping with Minnesota Centennial (1858-1958). Minneapolis and Minnesota, in general, should be proud of having participated in the State Association meeting which was in close conjunction with the first World Health Organization meeting to be held in this country. Both meetings were successful, and we are still receiving many compliments from various parts of this country and abroad relative to the format of the meetings and also to the wonderful Minnesota hospitality extended to those attending. And last but not least, the Clinical Session of the American Medical Association held in Minneapolis, December 2-5, 1958, was well regarded by those in attendance. We should be forever grateful and thankful to all the doctors and the many committee members who were responsible for the hard work and many hours required to accomplish such a feat, all in the same year.

Looking forward into 1959, there may not be so many major events, but we hope to have a very good annual State Association meeting which will be held this year in Duluth in May. The program is in progress and should be in readiness early this spring. The Minnesota State Legislature will be in session January through April, and we shall be expecting the usual fireworks. There will be many medical and welfare issues, as well as the osteopaths again confronting us to meet our challenge. I am sure, however, that as in the past, we shall all be willing and ready to join together in the best interests of the health and welfare of our people.

In closing, I wish at this time to extend my personal tribute to one Rufus R. Rosell, Executive Secretary of the Minnesota State Medical Association, who is retiring after more than thirty-two years. "Rosey" is a swell guy and we are going to miss him. It has been my pleasure to have worked with him more than twenty years, and I can assure you that he is worthy of the name "Mr. Executive Secretary" —not only in Minnesota, but on the national level as well. I am sure you will all join me in wishing "Rosey" and his good wife, Dorothy, many years of happiness.

MINNESOTA GOVERNOR URGES GREATER MEDICAL CARE FOR THE AGED

Minnesota's Governor, Orville L. Freeman, speaking before the opening session of the House of Delegates of the AMA in Minneapolis, appealed to the medical profession for greater co-operation with government in developing more adequate medical care for the aging programs.

Emphasizing the urgent need for a solution to this problem, Governor Freeman commented:

"We want to make sure that senior citizens whose incomes are small, yet enough for independence as long as no extraordinary expenses are required, need not become 'medical indigents' when they become ill. We want personal dignity as well as health for our later years."

Governor Freeman made these references to the Forand bill which would provide hospital and medical insurance benefits for those eligible under social security.

"It may not be a complete solution or the best solution," he said. "It may not be acceptable to you or to the Congress. But it would offer help to state governments, hard pressed to find ways to meet all the needs for services for which they are responsible."

He emphasized that the medical profession has the right to oppose such legislation as the Forand bill. In fact, he said the profession has the duty to oppose the proposed measure, if medicine believes the bill would be harmful to the public.

"But if you do oppose it," he declared, "you also have the responsibility of helping to work out an alternative program to meet the need that we all know exists and becomes more serious every day."

Governor Freeman pointed out that although social security pensions help the aged to meet ordinary living expenses, they are not sufficient to cover the expense of serious and chronic illness.

"Thus, there are increasing numbers of retired men and women who have earned pensions sufficient to meet their needs as long as they stay well, but insufficient to meet their medical care needs. If and when they become ill, those costs become an increased burden on government.

"Inflation has aggravated this problem . . . Surveys show that, while people past the retirement age need and do spend less on such cost-of-living items as food, clothing and shelter, in contrast they need to spend more on medical care. Their need for such care is probably double that of the average for the pre-retirement years."

In conclusion, Governor Freeman posed these questions:

"Can you help us find a way to apply the voluntary health insurance principle to elderly and retired people?

"Can you help us to develop a program, that is within our means, to provide the kind of preventive care and attention that will make the sunset years healthier and happier?

"Can you help us find ways to make available to all who need it the kind of physical rehabilitation that your scientific progress has already developed?

"We need this help and co-operation urgently. The people feel this need, and when they feel it badly enough, they demand that it be met. The people then say: 'There ought to be a law'."

PEOPLE WANT TO CHOOSE OWN DOCTOR, SURVEY SHOWS

More than three-fourths of the population of the United States want to choose their own doctor. In addition, they want to assume all or part of the responsibility for paying for their doctor bills.

These were among the findings in a survey conducted among a sampling of the adult general population by Opinion Research Corporation, Princeton, N. J., for the American Medical Association.

The purpose of the study was to explore attitudes about the choice of physicians.

The study also showed that:

Eighty-eight per cent of the population believe the right to see the same doctor regularly is of vital importance.

Eighty-nine per cent believe that medical care in this country has improved over the past twenty years. Half of these persons ascribe the improvement to more and better research and advances in medical science.

Seventy-six per cent of the people said they wanted to choose their own physicians; 13 per cent saw no difference in whether they or someone else chooses their physician; 8 per cent preferred to have someone else choose, and 3 per cent had no opinion.

In answering to further questioning, 93 per cent of those surveyed believed that free choice would give them more confidence in the doctor, 84 per cent thought doctors would take a more personal interest in them, and 79 per cent believed they would have less trouble getting the doctor to make a home call.

Concerning the right to see the same physician all the time, 88 per cent considered this right to be very important. Of the 12 per cent who did not believe such continuity to be of vital importance, 8 per cent saw no difference in whether or not they saw the same doctor every time, and 4 per cent gave other comments.

In answering still another set of questions, 93 per cent believed such continuity would give them more confidence in the doctor; 92 per cent thought doctors would take a more personal interest in them; and 84 per cent believed they would have less trouble getting a doctor to make a house call.

When queried about the main advantages of a regular doctor, those interviewed gave a variety of reasons. Sixty-two per cent cited the physician's knowledge of their medical history. They said, "He knows your system inside and out from dealing with you regularly; he knows what you've had."

Also mentioned by 30 per cent was reliability on emergency calls; confidence in the physician by 21 per cent; and a closer relationship between doctor and patient by 18 per cent.

Concerning the payment of medical bills, a total of 79 per cent wanted to assume all or part of the responsibility for paying their doctor bills either by direct payment or by paying part of insurance premiums.

AMA APPROVES AGED HEALTH INSURANCE PLAN

The AMA House of Delegates, during its recent Clinical Meeting in Minneapolis, accepted a recommendation of the council on medical service to provide low-cost voluntary health insurance for all persons over sixty-five with low income and resources. This action also had the approval of the AMA Board of Trustees. According to the plan, physicians would be urged to charge lower fees for such persons in order that they may obtain voluntary health insurance at reduced cost. Copies of the action will be distributed to medical society approved plans including Blue Shield and private insurance programs requesting their co-operation. This action will be taken in order to get the plan into effect as early as possible. Physicians under the low cost health plan would agree to accept lower fees from persons over sixty-five and on low income levels. Dr. Robert L. Novy of Detroit, Council member, pointed out that the plan contemplates a scale of graduated fees, dropping at some predetermined income point. The resolution does not fix such a cutoff.

Dr. Novy said some Blue Shield plans now offer such policies at local levels, but that Council members believed they should be adopted nationally. He called the resolution a recognition by physicians that the problem is their responsibility and that they are willing to do something about it.

"We believe this is a field where the government will act if the doctors don't," Dr. Novy said.

INSURANCE HEAD VOICES OBJECTION TO AGED INSURANCE RATE REDUCTION

Dr. Harry E. Ungerleider, Director of medical research for the Equitable Life Assurance Society of New York, in a recent address to the Association of Minnesota Internists, termed any plans to give certain age groups lower insurance rates "ridiculous." The leading medical insurance man pointed out that there is no "equity" in singling out one segment of population to be supported by the rest. Dr. Ungerleider, in making his remarks, referred to recent action of the AMA House of Delegates at its Clinical Meeting in Minneapolis, which asked for lower insurance rates for persons over sixty-five and for lower fees charged by doctors for those patients. "Somebody has to pay for this, why should doctors or any other group be singled out to subsidize others?" questioned Dr. Ungerleider. According to Dr. Ungerleider, the percentage of persons over sixty-five will hit near 35 per cent by 1980, and something will have to be done to provide extra medical care needed by this age group. Rather than special plans, Dr. Ungerleider favors adoption of a program comparable to that used by life insurance companies. Under such a plan, persons in their working years—twenty-five to sixty-five—should pay insurance rates that would carry them through the rest of their lives. He pointed out the "inequity" of the AMA proposal by commenting that if any part of the population really needs special attention, it is the newly married couple going through their first pregnancy.

Dr. Ungerleider told the Minnesota Internist

group that he was in favor of major medical insurance— deductible policies under which the patient pays part and the insurance company the rest of really high cost medical bills. The programs favored by Dr. Ungerleider would include provisions for determining the "deductible" figure by income and leave out "fee schedules," permitting the doctor to order done what he feels necessary with customary charges.

MEDICAL COST RISING WHILE PRICE INDEX HOLDS FIRM

For the second consecutive month, the consumer price index in United States cities remained the same in October. However, the medical care category continued its upward spiral. The latter showed a 0.4 per cent rise to 146.7 over the previous month and 5 per cent higher than the index for October, 1957 (1947-1949 = 100). The Bureau of Labor Statistics explained that group hospitalization insurance plans advanced in some cities and fees for professional services were higher. A slight increase in the price of prescriptions was also indicated.

PHYSICIANS WARNED TO STOP ABUSING INSURANCE

American physicians were recently urged to crack down on those who are playing medical care insurance for a good thing, or face the possibility of disciplinary action from the government. This, in effect, was the warning which came recently from George Bugbee, President of the Health Information Foundation, in an address before the annual scientific assembly luncheon of the Washington, D. C., Medical Society. He pointed out that the rise of prepaid health and hospitalization insurance has been accompanied by a certain amount of fee-bloating and over-usage of services and facilities. According to Mr. Bugbee, doctors and hospitals "must demonstrate to the public that the problems of over-use and excessive cost can be controlled" if growth of insurance is not to be retarded. Said Mr. Bugbee:

"I believe the time has come for these groups to coordinate and work out the necessary administrative structure to demonstrate to the public that the small percentage from their ranks who create these problems can be controlled.

"Without such demonstration, I am sure that pressure for government intervention in the financing and control of physicians and others in the health field will increase. We have already seen much government interest in some of these areas. If criticisms on these points become much greater, I believe government action is inevitable."

NEW INSURANCE CLAIM FORMS SIMPLIFIED

The Health Insurance Council reports that new simplified claim forms for accident and health insurance policies are being issued by insurance companies. A guide for physicians on the use of these new forms has been published by the Health Insurance Council. In the near future, a copy of this guide will be mailed from the Executive Offices to all members of the Minnesota State Medical Association. This service is made possible through the co-operation of the Health Insurance Council. It is entitled, "Simplified Claim Forms for Accident and Health Insurance—A Report to the Physicians."

The manual describes the principles of the Council program to reduce paper work for doctors and at the same time to provide insurance companies with the medical information they need to process and pay claims.

Ralph T. Heller, chairman of the Uniform Forms Committee and Second Vice President of the Prudential Insurance Company of America, describes the report as a supplement to a booklet distributed among insurance companies last year urging their adoption of the new forms.

"The response of the insurance business to the report to companies has been most gratifying," declared Mr. Heller. "A steady growing number of insurance companies across the country has adopted the simplified claim forms and others have made definite plans to do so. Now we want to tell our story to the nation's doctors, so that they may be better aware of what is being done to reduce the burden of their paper work and thereby better serve their insured patients."

Replacing a great variety of claim forms from hundreds of companies, the Health Insurance Council forms consist of two basic attending physicians' statements—one for group accident and health insurance, and the other for individual and family health policies. They are to be used solely in connection with accident and health insurance claims.

The forms comprise a standard set of questions, in a standard sequence, which are the minimum required to meet the provisions of most insurance companies. Some questions and phrases are optional and in many instances will not be required or

used by companies. The questions used, however, will be sufficient to provide the information needed to process routine claims of all types, including initial and continuing proof of disability as well as surgical and medical claims information.

JUST WHAT THE DOCTOR ORDERED?

The *Washington Stethoscope,* one of the several newsletters reflecting trends, news and views significant to the medical profession, recently reported the following account of Minnesota's Senator Hubert Humphrey's visit with Khrushchev.

"Some aspects of medical practice by American physicians may soon feel impact of a Western Senator's recent eight-hour session with Khrushchev.

"Political and military significance of Senator Hubert H. Humphrey's meeting with the Soviet chief has been played up in the press since his return home this week. Scant notice has been given fact that a *medical mission* sent him abroad in the first place and actually served as the vehicle for his historic visit to the Kremlin.

"Senator Humphrey went to Europe as chairman of a Congressional committee specifically directed 'to make a complete study of any and all matters pertaining to international health, research, rehabilitation and assistance programs.'

"The committee is scheduled to make its report to the Senate by Jan. 31, although it is not unlikely a time extension will be asked for and granted. That the report will recommend increased exchange of Russian and U. S. physicians and medical students and wider distribution of information in this country on Soviet clinical practices is all but certain, based on Senator Humphrey's disclosure this week.

"The Minnesota Democrat, who is proud he started out as a pharmacist, has exercised influence on national health legislation even though foreign affairs and agriculture are his main concerns. His stature heightened by the Moscow talks, Humphrey's words and views in 1959 on medical resources of U. S. will carry more weight than ever."

TECHNICAL AID URGED FOR HUNGRY NATIONS

Dr. G. Henry Sebrell, Jr., director of Columbia University's Institute of Nutrition Sciences, said in New York that he believes hungry nations of the world need technical assistance to combat malnutrition more than they need shipments of surplus food from the United States.

He said at a luncheon of Columbia Associates that surplus food shipments may stifle agricultural advances in underdeveloped countries. He believes that America should "help hungry people to feed themselves adequately within their own resources."—*AMA News*

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

MINNEAPOLIS MACHINIST SENTENCED TO SERVE THREE YEARS ON ABORTION CHARGE

On September 26, 1958, Elmer C. Hultgren, fifty years of age, 123 W. 26th Street, Minneapolis, was sentenced by the Hon. John A. Weeks, Judge of the District Court of Hennepin County, to serve a term of three years in the State Prison at Stillwater pursuant to his plea of guilty to an abortion charge previously entered before Judge Weeks on August 8, 1958. Before being sentenced by the Court, the defendant entered a plea of guilty to an information charging him with having a prior conviction for a felony. On May 17, 1946, Hultgren had been convicted of the crime of abortion in Hennepin County District Court at which time he was sentenced by Judge Lars O. Rue to a term of not to exceed four years in the State Prison, the execution of the sentence being stayed and the defendant placed on probation on condition that he serve the first year of his sentence in the Minneapolis Workhouse.

A representative of the Minnesota State Board of Medical Examiners signed a criminal complaint against the defendant in the present case after an investigation disclosed that he had aborted a St. Paul divorcee in June, 1957, for which he was paid the sum of $650.00, and that he had on three separate occasions in June, 1958, attempted to abort the same woman by the use of ergot, quinine tablets and a catheter. The woman also stated that although she had paid Hultgren nothing in 1958, he had made a charge of $300.00 for his services. When the defendant was arrested he had in his possession a satchel of the type used by physicians which contained among other things, 9 catheters and wires, a speculum, one forceps, sterile lubricant, penicillin, quinine, a roll of absorbent gauze and four one-ounce bottles of castor oil. Hultgren admitted that he had been performing abortions for a year prior to his arrest, the number of illegal operations performed by him during that time being approximately ten.

Hultgren, who has been employed as a machinist for many years by a Minneapolis concern, has another previous conviction, for practicing healing without a basic science certificate. On October 17, 1944, he was sentenced in Hennepin County District Court to a term of one year in the Minneapolis Workhouse but due to the fact that he was at that time employed in an essential job in a Minneapolis war industry, he was required to serve only two months of that sentence. Hultgren was born in Chicago and has lived in Minneapolis for forty-two years. He has no medical training of any kind but on one occasion while being questioned under oath Hultgren claimed that a convicted abortionist was the person who first instructed him in the performing of abortions.

The people aged sixty-five and over in the United States have been growing rapidly in number, and the outlook is that they will continue to increase markedly in the years ahead. Their total has grown by almost 5.4 million, or by 60 per cent, between the 1940 census and mid-1956. During this period of little more than sixteen years, the number of elders rose from 9.0 million to approximately 14.4 million, and their ratio to the total population increased from 6.8 to 8.6 per cent.—*Statistical Bulletin,* Metropolitan Life Insurance Company, March, 1958.

AMA WARNS PUBLIC OF FOOD FADDISM DANGERS

Food faddism is spreading with an alarming speed throughout the country, and the AMA is joining with the Food and Drug Administration and the National Better Business Bureau in a concerted program to inform the public of its dangers. We urge you to join in an educational campaign aimed at exposing this multi-million dollar racket which is costing some 10,000,000 Americans over $500,000,000 each year. The AMA points out that this program is important to the entire medical profession because these pseudo-authorities on nutrition are operating on a national scale with their peddlers and advertisements. Although many of these products contain harmless ingredients, they have become a menace to the public when their promoters make extravagant claims for their healing powers. Needless to say, the buyer who relies on vitamin-mineral concentrates and seaweed-cereal mixtures to cure unidentified ailments may face tragic results.

AMA Aids: For use of state and local societies in this campaign, the American Medical Association has produced a series of educational aids. All can be ordered from the Minnesota State Medical Association, 496 Lowry Medical Arts Building, St. Paul 2, Minnesota.

"The Merchants of Menace"—Eight-page, two-color pamphlet, outlining the dangers of food faddism. Available in quantities without charge, for distribution with monthly statements. Sample copies were included with the December Newsletter.

"Let 'Em Eat Hay"—By Joseph N. Bell—Reprint of an article in September, 1958, issue of **Today's Health,** presenting a comprehensive review of food quackery and nutrition "nonsense." Available in limited quantities for the waiting room reading rack.

"The Medicine Man"—Twenty-seven minute, black and white motion picture, produced in Hollywood especially for this campaign. Available for showing on television and to community groups. Available directly from the Communications Division, American Medical Association, 535 No. Dearborn, Chicago 10, Illinois.

WHOM DO YOU KNOW?

It's "whom you know" rather than "what you know" that often leads to a successful program of grass roots persuasion, a panel of medical society representatives concluded at a recent AMA Public Relations Institute session.

The key to effective persuasion, they agreed, is to know and be known on a first-name basis by the public opinion leaders in the state and community. Among these leaders are elected and appointed public officials; officers of business, industry and utility firms; key association executives; members of the communications industry; religious personages, and political party officials.

Aubrey Gates, Director of AMA's Field Service Division, who moderated the panel, said it is equally important for opinion leaders to know you. "They should be aware of your personality, your feelings and your sympathies," he said.

To dramatize the panel's "Whom Do You Know?" theme, pictures of seventeen prominent persons were flashed on a screen and the audience was asked to identify each. With the exception of such prominent personalities as Presi-

dent Eisenhower and AMA's Executive Vice President, Dr. F. J. L. Blasingame, audience identification was poor.

To overcome deficiencies in identifying key people the panel offered the following suggestions:

1. Keep a card file on every opinion leader in your state and community.
2. Get to know these leaders personally.
3. Make as many friends as possible.
4. Meet your public officials at the beginning of their careers.
5. Work closely with congressmen and members of the state legislature.
6. Keep abreast of legislative action on the national, state and local levels. Let your feelings be known on these issues.
7. Be a positive member of your community and lend your support to various civic programs.

MEDICAL ASSISTANTS RECEIVE PUBLIC RELATIONS TRAINING COURSE

There's a tremendous amount of "public relations" transacted by the girl at the doctor's reception desk, so any investment in her public relations education is well worth a medical society's money.

Doctor-patient relationships in Oneida, Herkimer and Madison counties in New York, should show a marked improvement now that 200 medical assistants from that area have completed a training course sponsored by the three county societies. The course was held one night a week for a month and included eight classes on poise, medical public relations, insurance, Medicare and office procedure. Instructors were drawn from a variety of sources inside and out of the medical profession. An airline stewardess briefed the group on grooming, a telephone company representative talked on telephone tips, and a member of the Workman's Compensation Board discused handling of eligible patients.

"DOCTOR'S HOUSE CALL" GETS NEW AND MORE TIME

The new radio series inaugurated on WCCO radio during the fall of 1958, is experiencing growing pains. Originally five minutes in length, the program time has been increased to ten minutes and is now heard Monday through Friday, from 6:30-6:40 p.m. on WCCO radio, 830 KC, Minneapolis.

"Doctor's House Call" features Dr. James Rogers Fox and his informal but informative presentation of health topics. "Your Health" is now heard each Sunday morning from 8:05 to 8:15 a.m.

"DOCTOR, TELL ME" COVERAGE AT NEW HIGH

The Minnesota State Medical Association produced program, "Doctor, Tell Me," is now heard on twenty-five radio stations throughout the state of Minnesota. In addition to Dr. James Rogers Fox, the fifteen minute weekly program features guests, Miss Audrey June Booth and Jerry Ball of the KUOM staff. Format of the series includes "Medical Facts & Fallacies" treatment, letters from the mailbag, and question and answer sessions.

YOU CAN HELP

Bring the information about these popular health education projects to the attention of your patients and community. Signs, placards, or display notices in local newspapers which give the time and date of "Doctor, Tell Me" broadcasts on the radio station in your area, might be a project worthy of consideration by county medical societies.

(See schedule of programs in December issue, Page A-54)

Public Health

UNIT FOR RECALCITRANT TUBERCULOSIS PATIENTS ANOKA STATE HOSPITAL

D. S. FLEMING, M.D.

The purpose of the Recalcitrant Unit at the Anoka State Hospital, in the words of the January 19, 1955, report of the Tuberculosis Facilities Commission, is to afford security, care, and treatment for "irresponsible people with active tuberculosis . . . originating from whatever source within the State of Minnesota." It is expected, however, that this 24-bed unit will not be adequate to accommodate every troublesome patient from the various sanatoria and other public hospitals and institutions. Therefore, the superintendent of the Anoka State Hospital, by delegation from the Commissioner of Public Welfare, must exercise judgment and discretion in approving admission of patients to this unit.

General

The following facts are taken from appropriate laws (Minn. Stat., Secs., 144.42 through 144.424):

1. A recalcitrant patient is defined as a patient infected with tuberculosis in the infectious stage who by his conduct or mode of living endangers the health and well-being of his family or other persons.
2. Cases of tuberculosis are reportable to the State Board of Health within 7 days after the date of diagnosis.
3. Any health officer who has knowledge of a recalcitrant patient may report this to the board of county commissioners.
4. If this board makes a finding that the patient is recalcitrant, it may, by resolution, direct that the patient be committed to the tuberculosis sanatorium or public hospital.
5. There is provision for appeal to district court both by the patient and by the health officer in the event that the findings of the county commissioners are unacceptable to either.
6. If the patient refuses to enter such institution, the resolution shall be filed with the clerk of district court.
7. The judge of this court shall order the apprehension of the patient and his deliverance to the designated institution.
8. If, upon appeal, the court finds that the patient is recalcitrant, the court will either commit the patient in the manner described above or, with the consent of the Commissioner of Welfare, may order the patient confined at the Tuberculosis Unit at Anoka State Hospital until such time as the Commissioner finds that the patient may be safely cared for at the sanatorium or hospital named by the court or can be discharged. The patient may be readmitted to Anoka by the Commissioner at any time during the remainder of the patient's hospitalization. There is nothing in the law prohibiting the court from making a dual commitment to the sanatorium or other public hospital and, with the consent of the Commissioner, to the Recalcitrant Tuberculosis Unit, Anoka State Hospital. Operationally, such dual commitment would take the least of the court's time and would facilitate transfer back and forth between the Recalcitrant Unit and the parent institution, as dictated by the bed situation, the degree of recalcitrance, and other variables.
9. Any health officer may make his initial petition for commitment of the recalcitrant patient directly to the district court.
10. Any patient entering any public sanatorium or hospital for the treatment of tuberculosis is subject to the regulations of that hospital. A patient who repeatedly violates such regulations or attempts or threatens to leave the institution without consent may be confined in quarters apart from the other patients or may be brought before the court for commitment as a public health menace, and in such case the superintendent or chief medical officer of the institution shall occupy the position of health officer.
11. A patient committed as recalcitrant may, no oftener than every six months, petition the district court for an order directing his release.
12. Any patient committed to a sanatorium or hospital who willfully violates regulations or leaves without consent may be brought before the commiting court by the superintendent; and the court may, with the consent of the Commissioner of Public Welfare, amend its commitment order, ordering the patient to be confined in the Tuberculosis Unit at Anoka State Hospital.

Admission Policy

1. The general policy will be that transfer will be made to the Recalcitrant Unit, Anoka State Hospital, only when such transfer either from the public health security or the medical point of view, will produce beneficial effects considerably

beyond the capabilities of the parent institution and with the proviso that the patient will be returned to the parent institution as soon as it is believed that the beneficial results have been attained.

2. The Commissioner of Public Welfare has delegated to the Superintendent of the Anoka State Hospital the exercise of his authority to give consent for admission to the Anoka State Hospital Tuberculosis Unit and the authority to return the patient to the parent institution. Direct communications among the State Sanatorium, public hospitals, the courts, and the Superintendent of Anoka State Hospital is authorized in these matters. A copy of such communications should be sent to the Commissioner, Attention: Medical Director.

3. The rate charged the counties for patients in the Recalcitrant Unit shall be the same rate that is charged for the care of tuberculosis patients at the Minnesota State Sanatorium.

Procedure

1. Public health officers, and superintendents or medical directors of the state and county sanatoria and other public hospitals, should take the necessary steps leading to the commitment of recalcitrant patients under their cognizance to the proper hospitals for the treatment of tuberculosis and dually to the Recalcitrant Tuberculosis Unit, Anoka State Hospital.

2. Such of those patients so committed who are so recalcitrant that they cannot be treated in a facility other than the Anoka Recalcitrant Unit may be reported to the Superintendent, Anoka State Hospital, with request for admission to the Tuberculosis Unit. Transfer of such patients will be effected dependent upon the space capabilities of Anoka.

3. Patients from state institutions operated by the Department of Public Welfare will be similarly reported; and transfer to Anoka State Hospital will be on the determination that Anoka State Hospital, by virtue of its special medical facilities, can enhance the treatment of tuberculosis in the particular patient.

4. As such time as it is deemed that the recalcitrant patient at Anoka may be amenable to treatment at the parent institution, he will be returned to that institution. If at all practicable, he will be returned to the parent institution in sufficient time to allow for discharge planning.

5. At such time as a patient in the Recalcitrant Unit at Anoka is considered as no longer recalcitrant by virtue of his reaching a noninfectious state, he will, upon his request, be released from the hospital whether or not it might be to his general medical benefit to remain hospitalized longer.

MINNESOTA STATE BOARD OF HEALTH REGULATIONS IN RELATION TO IONIZING RADIATION

The attention of all physicians in Minnesota is directed to the following discussion and the parts of a series of regulations adopted by the Minnesota State Board of Health on December 4, 1958, and filed with the Secretary of State on December 18, 1958. It should be specifically noted that these regulations have the force of law, and "Nothing in these regulations is to be construed to limit the kind and amount of radiation that may be intentionally applied to a person for diagnostic or therapeutic purposes by or under the direction of a licensed practitioner of the healing arts."

Of immediate significance to the medical profession in the regulations is a section which requires the registration of all sources of ionizing radiation with the Board of Health during the month of March, 1959. Sources of ionizing radiation include all diagnostic and therapeutic X-ray machines in hospitals, clinics, private offices, or at any other location within the State. Registration forms to be completed by "every person or institution who owns, controls or operates, directly or indirectly, any radiation source in this State" are available by writing or calling the Section of Radiation and Occupational Health, Minnesota Department of Health, University Campus, Minneapolis 14, Minnesota. By means of this registration the Minnesota Department of Health will develop and maintain an inventory of radiation sources.

Regulation 1153 (Registration) states specifically:

(a) Except as otherwise specifically exempted in these regulations, every radiation source shall be registered during the month of March, 1959, with the Board of Health upon forms prescribed and provided for that purpose. . . .

(c) The form for registration shall require, and the registrant shall furnish, the following information:
  (1) The name and address of the owner of the source.
  (2) The name and address of the person in charge of radiation safety in the installation, and a statement as to his qualifications for performing this work.
  (3) A description of the type and size of the radiation source.
  (4) The location of the radiation source.
  (5) A general description of measures taken to safeguard the health of all personnel and of the general public in regard to the use of these radiation sources.

The Board may also require such other information as it may deem relevant.

(g) The registration of any radiation source . . . shall not imply the approval by the Board of Health of the . . . operation . . . of such radiation source, but shall serve merely as notice to the Board of Health of the facts stated in such registration. . . .

Regulation 1154, relating to investigations, states, "any person in control of any radiation source in this State, upon request by any member of the Board of Health or any agent of the Board of Health duly authorized by it for this purpose, shall permit such member or agent to inspect any such radiation source and the place and premises upon and within which such radiation source is located, . . ."

Regulation 1160, relating to responsibilities, states that:

(a) Every person who owns or controls any radiation source subject to these regulations shall ensure that such radiation source is used only under the direction of a competent person who is responsible for the radiation safety therein, and whose name has been reported to the Board of Health. . . .

(b) The person in charge of the radiation safety in the installation shall have the following responsibilities:

(1) He shall inform himself of the hazards attendant upon the presence of radiation in the installation and, if necessary to this end, obtain the services of a qualified expert.

(2) He shall provide, . . . , any necessary instruction concerning the attendant radiation hazards and safe working practices to all employees whose duties necessitate . . . the operation of any machines that produce radiation in amount that leads to hazard.

(5) He shall ensure beyond reasonable doubt that any area, inside or outside the installation, normally occupied by adults not primarily engaged in radiation or associated work cannot be subjected to radiation levels exceeding the appropriate limits.

Other sections of the regulations, less applicable to the medical profession, prohibit the use of shoe-fitting fluoroscopes in Minnesota, require that plans for radiological safety programs for any nuclear reactor or facility must be submitted to the Board of Health for approval before construction commences, and stipulate that nuclear accidents must be reported promptly to the Board.

Having a baby is not only safer today for both mother and child than it was 25 years ago, but measured in equal dollars, it is also about 18 per cent less expensive, according to Health Information Foundation.

MINNESOTANS URGED TO WATCH FOR CASHEW NUTSHELL NOVELTIES

Minnesotans are urged to be on the lookout for novelties carved from cashew nutshells. The latest report to the Minnesota Department of Health from the United States Public Health Service indicates that these so-called voodoo doll heads have been used as decorations on children's straw slippers. A shipment was recently discovered in a large Cincinnati department store. Previously, use of the doll heads had been reported on such novelties as beverage swizzle sticks.

The cashew nutshell can have harmful effects on persons handling it. It contains a chemical similar to the oil in poison ivy and persons who handle it can develop blistering skin reactions. In addition, eyes of the doll are made of jequirity beans which could cause a serious or even fatal illness if swallowed by a baby.

It is believed that a great number of these novelties have been sold in this country, and it is now known that they have been marketed in Minnesota, according to Dr. R. N. Barr, State Health Officer.

The dolls are imports from Haiti. Only dolls carved from cashew nutshells are involved. Dolls from coffee beans do not cause trouble. The cashew nutshell is kidney shaped, an inch or more long, and about three-fourths inch wide. Coffee beans are much smaller. The jequirity bean is about the size of a small pea, and is essentially red or orange with a variable area of black.

NURSING GRANTS TOTAL $6 MILLION

The Public Health Service will award $6 million this year to colleges and universities for grants to registered nurses for advanced preparation in administration, supervision of nursing service, and teaching methods.

About 1,500 registered nurses will benefit from these grants, Dr. Leroy E. Burney, surgeon general of the service said.

The appropriation by Congress for the Professional Nurse Traineeship Program was doubled for fiscal 1959.

A limited number of traineeships will be given to nurses now enrolled in baccalaureate programs in nursing.

Thirty-nine additional schools are being offered traineeship funds this year, bringing the total number of schools to 99.

At a national conference in Chicago in August, nursing and health leaders recommended that the program, authorized by Congress for three years in Health Amendment Act of 1956, be continued at least five more years.—*AMA News*

History of Medicine in Minnesota

A MEDICAL HISTORY OF MEEKER COUNTY PRIOR TO 1900

HAROLD E. WILMOT, M.D.

Litchfield, Minnesota

(Continued from October, 1958, issue)

Dr. Charles A. McCollom was Dassel's first physician, arriving there in 1871 and selling his practice to Dr. J. F. Kauffman of Newburg, Pennsylvania, for $250.00 on December 1, 1887. He then moved to Minneapolis.

He was a graduate of Rush Medical College in 1868; his Minnesota Medical License No. 797 was granted February 6, 1884. A regular, he was listed in the directories since 1890 as residing in Minneapolis. He was reported by the American Medical Association as having been born in Binghamton, New York, on July 2, 1847. He was licensed in California in 1918, and died at Pasadena, California, January 22, 1926. He was formerly connected with the Medical Department of Hamline University.

Dr. Karl Danielson states: "He was a sincere Christian and was active in the religious, social, and civic life of the community. He served as village recorder of Dassel and as County Commissioner of Meeker county from 1878 to 1880. He bought and ran a drugstore in Dassel in 1880, which he sold to Mr. Rudberg in 1883.

Litchfield Ledger, August 28, 1873—(Dassel News). "Dr. McCollom is busy erecting a new office and in a short time will, in company with a Mr. Bell, start a drug store here."

News Ledger, January 8, 1879—"Dr. McCollom of Dassel is chairman of the Meeker county Board of Commissioners this year."

News Ledger, August 22, 1881—"Dr. McCollom was one of four delegates from Meeker county to the Minnesota State Republican Convention."

News Ledger, March 20, 1884—"Dr. C. A. McCollom of Dassel is the secretary of the Pension Board of this local district." (Drs. Bissel of Litchfield and Kee Wakefield of Hutchinson were the other members.)

News Ledger, July 22, 1886—"Dr. McCollom of Dassel was appointed by Gov. Hubbard as one of the delegates to the National Conference of Charities held in St. Paul, and he attended that gathering last week."

Independent, December 10, 1886—(Dassel News). "Dr. Charles A. McCollom is about selling out preparatory to moving to Minneapolis. He will leave a large practice and many will regret his departure. It will be an opening for someone well qualified to treat those in need of medical skill."

Dr. McCollom did move to Minneapolis as before noted and conducted his office in the Masonic Temple building at Sixth Street and Hennepin, with his residence on Sixth Avenue North. In 1890 he became Medical Director for the Modern Woodmen of Minnesota and held this position for a number of years. He retired from practice (?) in 1918 and moved with his family to Carmel, California, which became their future home.

Dr. Edward J. Brown of the Minnesota State Board of Health in his "Reminiscences" published in 1925 and 1926 is quoted: "Visiting Dassel November 12,

1884, he found Dr. C. A. McCollom there. He was a former member of the Hennepin County Medical Society and later returned to Minneapolis and was at one time president of the Hennepin County Medical Society. Dr. McCollom died within the past year at Los Angeles.

"At Dassel, they hunted strenuously, and with some success, for cases of variola. It was a cold day and they were obliged to satisfy their hunger by eating raw turnips, as preferable to the opportunities we met at the houses on the route. The excellent oyster stew served by his good wife in the evening was some recompense."

There were similar news items of Dr. McCollom's medical and surgical treatments mentioned in local news columns, and they also mentioned how well he had done generally and the great disappointment in losing him to Minneapolis (as indeed it was).

Dr. Elam Stiles Gibbs was a practitioner of the regular school and apparently was induced to come to Litchfield to assist Dr. V. P. Kennedy during the years 1872-73, as we find their professional card together in the newspapers of that year. He came from Glencoe (McLeod County). No doubt, Dr. Kennedy tried to obtain an assistant to handle his practice during his frequent absences. There is some confusion as to just what happened, but I would believe from the following newspaper reports that he separated from Dr. Kennedy in 1873 and practiced independently in Litchfield until about 1880, when he moved to Monticello, Minnesota.

News Ledger, January 1, 1874—"Dr. E. S. Gibbs, formerly of Glencoe, has removed his family to Litchfield." [In another column we give what the *Register* (Glencoe) has to say about his leaving that place.] "In our small acquaintance thus far, we find him a gentleman and a first class physician."

A paragraph from the *Glencoe Register* expressed extreme regrets at his leaving.

News Ledger, May 20, 1875—"Dr. E. S. Gibbs has a card in another column. Doc. is ready night and day for all who may call on him."

Independent, August 3, 1886—"Dr. E. S. Gibbs, formerly a resident of this city but now residing at Monticello, is a brother of candidate for governor, Gibbs."

Transactions of Minnesota Medical Society list Elam Stiles Gibbs as having been graduated from Charity Hospital Medical College, Cleveland, Ohio, 1869, and receiving Minnesota Medical License No. 131, October 12, 1883. They listed him in Glencoe in 1872. He was reported by the Minnesota Historical Society as practicing in Monticello in 1883. They also reported that Polk's Directory of 1900 listed an E. S. Gibbs at Minneapolis. Our directories list him at Monticello from 1890 to 1909, and the A.M.A. Directory of 1927 listed him there.

The death certificate stated he was born May 1, 1847, in Pennsylvania and died August 3, 1922, when seventy-six years of age, at Monticello, Minnesota, from a cerebral hemorrhage. Burial was at Geneva, Minnesota; information given by Martha Gibbs, and certificate signed by F. E. Ellison, M.D.

The medical history of Freeborn county, Minnesota, lists an E. *M.* Gibbs born at Rome, Bradford county, Pennsylvania, in 1847. He read medicine with Dr. A. C. Wedge. Dr. Wedge reported for him a case of Cesarean Section performed in that neighborhood by an old woman. His graduation college and date is correct, and he practiced in Geneva, Freeborn county, one year, evidently moving from there to Glencoe and later Litchfield and then Monticello as outlined here. His middle initial must have been erroneously read from an "S" to an "M" in Freeborn county files.

Dr. James S. Gibson (regular) located in Atwater, Minnesota, one mile west of Meeker county's boundary about October 15, 1873, having left New London, Minnesota, at that time. He is listed here because from the beginning Atwater physicians have attended many patients in our county.

There are many excerpts in the regional news columns of his having attended patients for various illnesses, as we find concerning other doctors, but in some manner Dr. Gibson's cases revealed the most gruesome details of any I have read.

The last recorded news item in our local papers was August 21, 1881, which may or may not mean he ceased practicing about that time. Perhaps the Kandiyohi county historians will uncover further pointers. Minnesota medical directories give us the following:

James S. Gibson was born in Ayr, Ontario, November 9, 1842. He came with his parents to Minnesota in 1853. He graduated from Chicago Medical College in 1869. He possessed Minnesota Medical License No. 319, issued November 12, 1883, and his address was listed as Atwater in 1890 and 1909.

Word of mouth has it that he was a fine country doctor, well liked and had many thrilling experiences with early transportation, the elements, and even wolves.

Dr. C. L. Armington.—I believe his story is well contained in the following squibbs:

News Ledger, January 1875—"Dr. C. L. Armington of Minneapolis called on us Tuesday last. The doctor is hunting up a location and comes well recommended."

News Ledger, February 11, 1875—"Dr. Armington has located in this village. He boards at McCarey's, south side of the tracks. He is said to be an excellent physician."

News Ledger, July 8, 1875—"Mrs. Hayford has been suffering with a severe attack of erysipelas in the face and eyes which made her blind for some time, but under the skillful care of Dr. Armington is getting better fast."

News Ledger, September 26, 1875—"Dr. Armington left here on Tuesday for Terre Haute, Indiana, where he purposes to reside and fight chills and fever for the remainder of his natural life. Doc. says he loves Minnesota, but it is too healthy for his business."

Dr. Lysander P. Foster, a homeopathic physician, located in Litchfield in May, 1875. The *News Ledger* states: "He has purchased the old schoolhouse and is fixing it up for a residence." A. C. Smith's *History of Meeker County* lists him as one of the physicians of Litchfield in 1876.

Transcripts of Medical Society of Minnesota give this information:

Graduated, Hahnemann Medical College of Chicago, 1882; Minnesota Medical License No. 131, October 12, 1883. Recorded address: 1890, Minneapolis. He apparently left Litchfield within a few years. Dr. Rosenthal records his death at eighty-eight years of senility on April 7, 1924.

Dr. C. J. Erickson.—We have previously read his letter in the local *News Ledger* in response to one from Dr. V. P. Kennedy in regard to his license to practice the healing art.

News Ledger, March 30, 1882—"Dr. Erickson of Grove City has sold out his Scandinavian paper to some young men who have been in his employ for a year or two past."

Independent, June 17, 1884—(Grove City News). "Dr. C. J. Erickson, former resident of this place, has now located in Minneapolis where he intends to practice his profession as a doctor. It is claimed that the doctor has reformed and become a good Christian and missionary. The latter statement is very doubtful, and is one of the biggest wonders of the nineteenth century, if true."

Dr. Charles Weinsma.—

News Ledger, June 6, 1877—"Dr. Weinsma, a young man who has lately located as a practicing physician at Forest City, publishes a card to that effect in another column of this issue."

"C. Weinsma
Physician and Surgeon
Office at J. B. Atkinsons, Forest City"

News Ledger, October 31, 1878—"Dr. C. Weinsma, who has been located at Forest City for the past year and a half has moved to Litchfield."

News Ledger, February 20, 1879—"Dr. Weinsma published his directions for healing colds."

News Ledger, June 5, 1879—"All For a Dog."

"Vick Weems and Dr. Weinsma had a slight difficulty over a dog. Some choice language was indulged in, when ye mighty doctor smote the vanquished Victor on the shoulder. Vick had him brought up before Judge Atkinson, and the Dr. was fined $5.00 and costs, the whole amounting to $13.95. The Doc not having the wherewithal to pay the same, a commitment was placed in the hands of Officer Hooser. W. W. Rollins came to his rescue, rather than see him go to jail. He now wishes he hadn't been quite so kind-hearted, as the doctor forgot to fix the matter up with him before he started for foreign parts.'

Independent, December 22, 1885—"Dr. Weinsma, several years ago a resident practitioner in this city who left town rather suddenly (so much so in fact that he forgot to pay sundry bills), is now one of the leading physicians of Wheaton, Dakota Territory, and coroner of Richland county. His friends here will be glad to hear that he is prospering."

Transcripts from Minnesota Medical Association: "Weinsma, Charles; graduate of University of Utrecht, Holland, 1872; Minnesota Medical License No. 963, September, 1884; Regular." From Minnesota Directories: 1890—Winona, 1895—Bellingham; Deceased—Place of death was evidently Bellingham, but date is not given. No record in A.M.A.

Dr. James Fair probably practiced part-time in Paynesville (Stearns county) and Manannah (Meeker county). According to an "old settler," he had his office in the Manannah hotel in the 1880's and "went to Paynesville and died there."

[At this time, lumbering, milling, the stagecoach and the buzz of settlement made this village (Manannah) on the banks of the Crow River in the northern part of the county, a center.—Ed.]

News Ledger, June 19, 1879—"The oldest son of J. D. Amos has been dangerously ill the past week but is now recovering fast under care of Dr. Fair."

News Ledger, January 13, 1881—"Dr. Fair treated the Manannah school teacher."

News Ledger, December 22, 1881—"Dr. Fair is busy vaccinating the school children of this village."

News Ledger, June 8, 1882—"Dr. Fair is doing a lively business. We saw him smiling this morning, something is up."

News Ledger, July 13, 1882—"Dr. Fair, formerly of Manannah, has moved to Paynesville, so we are told."

News Ledger, February 29, 1884—"Drs. Spencer and Fair are healing the sick as usual."

Independent, August 23, 1884—"Dr. Fair testified in re a gunshot wound received by Owen Gibney in neck and back by his father. He is a practicing physician residing (sic?) in Manannah."

Independent, March 23, 1886—"Dr. Fair attended Shaughnessy with Dr. Newlands of Litchfield and amputated his left arm which was shattered by goose shot fired by one Tom Walch. Gangarene set in and Shaughnessy died."

No information is available in Minnesota Medical Records on Dr. Fair. The old settler tells me he was tall and skinny, wore a moustache and chin whiskers, and married a widow in later years.

Dr. C. B. Spencer first appears in the news items of the *Litchfield Ledger*, June 19, 1879:

"Dr. Spencer has finally been compelled to rent an office and go into practice. When he first came to this place, he gave it out that he did not intend to practice and would not. But one after another, cases have accumulated upon his hands, until he is kept busy most of the time. He has his office over Brill's drug store."

The old settler states that Dr. Spencer was in Manannah before Dr. Fair.

News Ledger, December 22, 1880—" 'A patient was made happy by skillful treatment by a Dr. Spencer.' Signed by Charles E. Garrison, Post Master, Roseville, Kandiyohi County. 'Treatment and medicine cost $35.00, cured his palsy.' "

News Ledger, August 11, 1881—"It is with pleasure that we announce the recovery of Mrs. M. Buckley under the skillful treatment of Dr. Spencer of Litchfield."

News Ledger, January 4, 1883—(Courtesy Card). "Physicians: Spencer, C. G. Office on 3rd Street, west of McLane's Store."

News Ledger, February 29, 1884—(Manannah News). "Dr. Spencer and Fair are healing the sick as usual."

Independent Review, May 20, 1884—(Manannah News). "Mrs. Rosie Phillips was stricken with acute rheumatism of the heart and stomach. Dr. Spencer was called, and at 6 p.m. she was up and about and ready for her rations."

Independent, January 13, 1885—"Dr. Spencer of Manannah is building a furnace in Rodalph's blacksmith shop to melt ore."

News Ledger, January 8, 1885—"Doc Spencer showed us some specimens of gold from the Manannah mining district; there is no doubt but that it is the pure root of all evil, and the only question is whether it can be found in paying quantities. Doc says he intends to thoroughly test the matter as soon as possible."

Independent, February 3, 1885—"If Spencer's gold mine is a success . . ."

Independent, October 26, 1885—"Dr. Spencer's chimney caught fire and burned his house down. He will rebuild."

Independent, January 4, 1886—(Grove City News). "Doc Spencer suddenly pulled stakes last Wednesday and emigrated only with the promise to return here again in May."

No more news items regarding Dr. Spencer could be found, nor a Minnesota Registration.

Dr. A. H. Carvill.—In the history and biography of Meeker county we find it stated that Dr. A. H. Carvill and his brother Jefferson had taken up a millsite in 1866, put up a sawmill and gristmill which constituted the entire business of this place. In 1873 the doctor sold out to John Norgren, and the firm was then operated under the name of Carvill and Norgren, Jefferson Carvill sole proprietor, but the firm then became silent due to litigation.

At that time Jefferson Carvill receives credit for laying out the town of (East) Kingston.

Dr. A. H. Carvill testified with logic in the trial of G. W. Donohue (sic) (Donovan), accused of the murder of James Flynn. According to Dr. Rosenthal, Dr. Carvill died at age ninety on November 3, 1933, of cerebral arteriosclerosis.

As to his exact status as a true physician, we cannot be sure, for we find nothing more of a medical nature than the fact that he testified in the trial of James Flynn, who was killed by gunshot wound, and his testimony was not of a definite scientific nature.

Dr. Westcott.—

News Ledger, February 24, 1881—(Dassel News). "Mrs. Simon Pratt who has been suffering so long with rheumatism is now improving under the skillful care of our esteemed citizen, Dr. Westcott. Electric treatment is now employed."

[Quack?—AUTHOR]

Dr. James Campbell.—

News Ledger, September 8, 1881—"Dr. James Campbell, M.D., of Hartford, Connecticut, will visit Litchfield September 18 and remain ten days. He has made a specialty of women's diseases and has been successful in the treatment of such. Any desiring to consult him or receive treatment will find him fully prepared to give the same. For further particulars, inquire of F. V. DeCoster.

[Dr. Campbell was a brother of Mrs. DeCoster.—AUTHOR]

Dr. L. Hall.—In October 27, 1881, we find the *Litchfield News Ledger* carrying the following two items, viz:

"Notice: Dr. L. Hall, Homeopathist and Electric Physician, has permanently located in Litchfield and is prepared to treat any and all cases that may be submitted to him. Office at present at E. B. Scofield's Residence. L. Hall, M.D."

In another place in the same edition we find:

"Rev. L. Hall resigned the position of pastor of the M. E. Church some time since, and last evening a meeting of the church people was held, at which the presiding elder was present. It was requested of the meeting that Rev. Hall fill the pulpit of the M. E. Church until a man could be found to take the same. This Mr. Hall has consented to do. He will continue his practice of medicine just the same, reports to the contrary notwithstanding."

We find in the *News Ledger* of December 15, 1881:

"Notice: Dr. L. Hall, Homeopathist and Electric Physician, has permanently located in Litchfield," et cetera.

There are no further news items or reports except

News Ledger, December 22, 1881—"Dr. Hall leaves this week for Chicago to attend the winter course of lectures at Hahnemann Medical College. Before his departure his many friends in Litchfield presented him with an elegant silver water pitcher costing between $20.00 and $30.00 as a token of their esteem and friendship. Accompanying the same with the hope that he make his permanent home in this place."

News Ledger (same date), December 22, 1881—"Dr. Hall who had arranged to leave for Chicago today is unexpectedly detained and will stay until Monday next."

No further news of Dr. Hall (Ed.), but the impression is that he was continuing an unfinished course in homeopathy at Hahnemann.

Dr. Kee Wakefield of Hutchinson, Minnesota, was a very active and conscientious practitioner of McLeod county during the 1880's. He was a charter member of the Crow River Medical Society and a member of the local Pension Committee. On August 20, 1889, he was delegated to examine local candidates for West Point. Further details of his career should be furnished by McLeod county.

[His progeny were rather striking people to my personal knowledge and acquaintance.—AUTHOR]

Dr. Granville Ira Smart, regular, practiced in Grove City during the year 1881, not, evidently, for a very long time. Dr. Roscoe C. Hunt has written up his biography in "Pioneer Physicians of Faribault County." He spent most of his years of practice in Blue Earth City, Minnesota.

Dr. Smart was born in Fryborg, Maine, November 14, 1853. He graduated from Fryborg Academy and attended Bardon's College, Brunsvick (Brunswick—Ed.), Maine. He taught school between semesters; graduated from Dartmouth Medical School in 1880; remained in Blue Earth City until 1901. Because his health was poor, he removed to Ontario, California, where he practiced until his death in

1906. He was a Mason and a member of the Methodist church. He had six children, three living in 1942, one (Elliot) a physician at Murphys, California.

Minnesota Directory, 1890: Blue Earth, and there registered until he died.

News Ledger, Litchfield, Minnesota, December 9, 1881—"G. I. Smart of Grove City has frequent medical calls in this vicinity."

Dr. Theron H. Bly.—On Dr. Bly, regular, the *Litchfield News Ledger* carries this September 4, 1882:

Courtesy Card
"Dr. Theron H. Bly, Physician and Surgeon
Grove City, Minnesota
Night calls promptly responded to."

News Ledger, June 15, 1882—"Among the professional cards will be found that of Dr. T. H. Bly who has lately located at Grove City."

His last professional card in the *Litchfield News Ledger* appears October 18, 1883, and his address is Grove City then.

Independent, December 16, 1884—(Manannah News). "Dr. Bly has his store building at Paynesville about ready for drugs."

News Ledger, 1885—"Dr. Bly practicing from Paynesville on Manannah patients."

News Ledger, June 31, 1888—"The people of Paynesville are trying hard to get some good man to go there and take the drug store lately left an orphan by Dr. T. H. Bly, who years ago was located at Grove City for a short time. This small speciman of a man, who by some hook or crook was permitted to attach the handle Dr. to his name, left Paynesville between two days because he could not withstand the temptation to sell poor whiskey without a license, and the iron clutches of the law were trying to fasten themselves upon him. He deserted a wife and one child, and we are informed that since his departure, the wife has disappeared, leaving the child to the cold charities of strangers, leaving the word that the doctor would come back and take care of his own young one. The doctor's present whereabouts is a mystery, but if he ever dies and anybody asks us to tell where he is likely to find him, we will direct them to the bottommost pit of Sheol."

Independent, June 29, 1886—(Manannah News). "Dr. Bly and Ostrander were taken to St. Cloud by sheriff Mickley last week charged with selling liquor without a license."

Editor Frank V. Cargill of the Directory of the A.M.A. offers this:

Records of the Directory Department were established in 1903, and of that time we attempted to obtain information on all physicians who were in practice since 1865.

We note that Theron H. Bly was listed in 1902 edition of Polks' Medical Directory at Minneapolis. This book states that he graduated from the University of Boston, Massachusetts, in 1876, the University Medical College, Kansas City, Missouri, in 1893, and took special courses in diseases of women at the University Medical College, Kansas City, Missouri, in 1894.

He is listed as Medical Examiner at Westfield, Massachusetts, and also as Medical Examiner of A.O.U.W. and for the Independent Order of Odd Fellows. His specialty was the diseases of women, and was listed as the physician in charge of Dr. Bly's Sanitarium which apparently was located at 3009 Harriet Avenue, Minneapolis. His name does not appear in the first edition of the American Medical Directory which was issued in 1906, and apparently he died sometime between 1902 and 1906.

Dr. William Chapman, regular, was born in Hill, New Hampshire, February 9, 1857, and was educated in the schools of New Hampton, New Hampshire, and

the University of Vermont at Burlington, Vermont; he graduated from the Medical Department of that institution in 1879.

He located in North Branch, Minnesota, and practiced there until 1882 when he came to Forest City and remained there until 1885. In December 28, 1882, he was married to Miss Georgia Kimball at Forest City by Rev. Charles W. Booth at the home of the bride's father, Edwin Kimball. "They will be at home to her friends until January 2, 1883, at the residence of her parents. No cards."

Further: "Dr. Chapman is a young man of sterling worth and well thought of in this section of the country, and his happy bride, Miss Georgia Kimball, is one of Meeker county's banner young ladies, having grown up at her home in Forest City. *The Ledger* hereby extends congratulations and well wishes, hoping that life may ever look as joyful to them as it did on their wedding day.—Doc Shake."

"In 1885, Dr. Chapman moved to Litchfield where he has since been active and successful in the practice of his profession. By training and practice Dr. Chapman is ably qualified to administer to the needs of ailing humanity, and he has been successful in a measure quite beyond that often reached in a community this size. He is a member of the Minnesota State Medical Society and Crow River Medical Society and is affiliated with the Odd Fellows, Workmen and Woodmen Societies."

Dr. Chapman was the son of John W. Chapman and Charlotte Toplin Chapman. No children were born to Dr. Chapman. Dr. Chapman was listed in the Minnesota Medical Directories in 1886 and 1890 as residing in Litchfield with License No. 778 dated January 26, 1884. His professional card appeared in the *News Ledger* in July, 1884, as physician and surgeon. The *News Ledger* went enough farther to announce in another column:

"He is a first-class gentlemen and understands his business; we wish him unboundless success."

In 1884: "Dr. Chapman has moved his family to Litchfield."

December 14, 1884: "Dr. Chapman moved his office over McLane's (grocery) Store."

We note that both the Republican and Democratic papers carried the news of his arrival to Litchfield.

Many further news notes appeared certifying to his presence in our midst as a doctor, but no drastic illustrations of medical treatment and surgery were ever found. Dr. Chapman joined with Dr. G. A. C. Cutts shortly after the turn of the century, and they practiced together in harmony until the death of Dr. Chapman by heart disease February 16, 1921.

Needless to say, many news items were published in the local papers in regard to Dr. Chapman's care of the sick. Further, I have the word of mouth from many of his patients who eventually came to my care that he was one of the finest. May I include the accolades of the nurses who knew him.

Dr. Chapman was rather small, wore a black moustache, seemed always rather polished and fine, was kindly, "straight-laced" and aristocratic.

The author and compilor had the privilege of being associated as medical assistant to Dr. Cutts, who in turn was Dr. Chapman's partner after 1900. My personal opinion was that these men were fine.

(To be continued in April issue)

STAPHYLOCOCCAL INFECTIONS

Excerpts from Reports Read at the Antibiotics Symposium

Spontin In Treating Severe Respiratory Infections –"In 13 of 20 patients the results were excellent, with clinical response being evident within one to four days after institution of therapy. In three additional patients, there was some degree of improvement in pneumonic processes superimposed on tuberculosis in two cases and on pulmonary neoplasm in one. In all other cases, serious antecedent pathology undoubtedly influenced the negative or equivocal response to ristocetin therapy.[6]"

Spontin In Treating Staphylococcal Infections–After successfully treating 28 patients, the authors wrote, "Ristocetin or Spontin has proved to be bactericidal and bacteriostatic, particularly for the *Staphylococcus aureus,* which is often resistant to many other antibiotics.[5]"

Spontin In Treating Seven Difficult Cases – "Ristocetin has produced excellent results in eradicating, mitigating or preventing infection in seven selected difficult cases. Six of the seven cases involved *Staphylococcus aureus* which did not respond to chemotherapy with other antibiotics.[7]"

Spontin Blood Levels In Children – "Ristocetin was administered as a single intravenous injection of 12.5 milligrams per kilogram. This resulted in serum levels ranging from 1.3 to 10.6 mcg. after two hours with a gradual fall to a level of 0.7 mcg. per cubic centimeter or less after 12 hours.[8]"

Spontin In Treating Staphylococcal Pneumonia –"Ristocetin was used in the treatment of 24 patients with staphylococcal pneumonia, 17 of whom had failed to respond to previously administered antibiotics. Complete clearing of pneumonitis was obtained in 16 patients and significant improvement occurred in two others. Two patients died of pneumonia; four others succumbed to other lethal diseases.[9]"

Spontin In Treating Children and Adults – "Ristocetin completely controlled severe staphylococcal infections in 11 adults and six children who received adequate therapy.[10]"

Meetings and Announcements

NATIONAL

American Academy of General Practice, credit course. Sponsored by Northeast Florida Heart Association. Annual seminar on Cardiovascular Diseases, Prudential Auditorium, Jacksonville, Florida, February 19-21, 1959.

American College of Allergists Graduate Instructional Course and Annual Congress, March 15-20, 1959, Mark Hopkins Hotel, San Francisco, California. Contact: John D. Gillaspie, M.D., Treasurer, 2049 Broadway, Boulder, Colorado.

American College of Surgeons sectional meetings:

February

Sectional Meeting, Shamrock Hilton Hotel, Houston, Texas, February 2-4. Dr. J. Griffin Heard, Houston, Local Chairman; Dr. Michael L. Mason, Secretary, 40 East Erie Street, Chicago 11, Illinois.
Sectional Meeting, Hotel Vancouver, Vancouver, B. C., February 26-28. Dr. T. R. Sargeant, Local Chairman; Dr. Michael L. Mason, Secretary, 40 East Erie Street, Chicago 11, Illinois.

March

Four-day Sectional Meeting for Surgeons and Nurses, Kiel Auditorium, St. Louis, Missouri, March 9-12. Dr. Frank McDowell, St. Louis, Local Chairman for Surgeons Meeting; Miss Joyce Brueggeman, R.N., Local Chairman for Nurses Meeting; Dr. Michael L. Mason, Secretary, 40 East Erie Street, Chicago 11, Illinois.

April

Four-day Sectional Meeting for Surgeons and Nurses, The Queen Elizabeth Hotel, Montreal, Quebec, April 6-9. Drs. Harry S. Morton and Charles Edouard Hebert, Montreal, Local Chairmen for Surgeons Meeting; Miss Moyra Allen and Sister Denise Lefevre, Montreal, Local Chairmen for Nurses Meeting; Dr. Michael L. Mason, Secretary, 40 East Erie Street, Chicago 11, Illinois.

September

Annual Clinical Congress, Atlantic City, New Jersey, September 28-October 2. Dr. Michael L. Mason, Secretary, 40 East Erie Street, Chicago 11, Illinois.

Chicago Postgraduate Course in Arthritis and Related Conditions, February 19, 20 and 21, 1959, Thorne Hall, Northwestern University, Lake Shore Drive at Superior Street, Chicago, Illinois. Tuition $50. Frank R. Schmid, M.D., 303 East Chicago Avenue, Chicago 11, Illinois, Secretary.

Mediclinics, fourth annual refresher course of postgraduate medical education, Fort Lauderdale, Florida, March 2-12, 1959. (Acceptable for 32 hours of postgraduate study—Category I credit for American Academy of General Practice members).

INTERNATIONAL

Association of the National European and Mediterranean Societies of Gastroenterology sixth meeting, Leiden, The Netherlands, April 20 to 24, 1960.

MAYO CLINIC REVIEWS DATES SET

Staff members of the Mayo Clinic and the Mayo Foundation for Medical Education and Research will present again this year a three-day program of lectures and discussions on problems of current interest in general medicine and surgery, April 13, 14, 15, 1959.

Up to twenty-one hours of Category I credit may be obtained by American Academy of General Practice members who attend.

There are no fees for this program.

The number of physicians who can be accommodated is necessarily limited. Those wishing to attend should communicate with the Clinical Reviews Committee, Mayo Clinic, Rochester, Minnesota.

SUBMISSION OF BILLS FOR SERVICES RENDERED TO ARMY MILITARY PERSONNEL BY CIVILIAN HOSPITALS AND PHYSICIANS

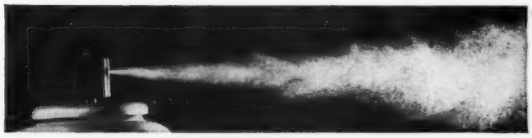
As a general rule, civilian medical agencies are aware of the appropriate channels for submission of their charges for care furnished Army military personnel. They are informed of the correct procedure, either by prior arrangement with the appropriate military authority for routine medical care of personnel under their jurisdiction, or through notification to the patient's Commanding Officer, or the Surgeon of the Army area in which emergency type of service is rendered.

In situations where the above does not apply or when the civilian medical agency is in doubt concerning the normal procedure, bills may be submitted directly to Headquarters Fifth US Army, Office of Army Surgeon, 1660 East Hyde Park Boulevard, Chicago 15, Illinois, with a request that they be placed in appropriate channels for settlement.

Such bills should show name, rank, service number, organization and duty station of the patient, disease or disability treated, inclusive dates and nature of the services, and a brief statement of the incident leading to the treatment.

The above pertains *only* to care of military personnel, and should *not* be confused with the established procedures for the processing of claims for care of eligible military dependents under Medicare.

MAYO CLINIC ANNUAL STAFF MEETING



Dr. O. T. Clagett, head of a section of surgery, was elected president of the staff at the annual meeting of the staff of the Mayo Clinic to succeed retiring president, Dr. G. J. Thompson. Other officers elected were Drs. H. W. Schmidt, vice president; C. A. Owen, Jr., secretary; and W. G. Sauer and G. W. Daugherty, councilors. Re-election of Dr. J. T. Priestley, present chairman of the Board of Governors of the Mayo Clinic and head of a section of surgery, and Dr. C. F. Code, chairman

Greater comfort...

faster healing after anorectal surgery

when your standing orders specify

TUCKS®

soft cotton flannel pads saturated with witch hazel (50%) and glycerine (10%), pH about 4.6

Postsurgical patients appreciate the extra comfort, the "extra attention" of *TUCKS:*

- Soothing and astringent
- Not greasy
- Allows free drainage
- Always handy, eliminating time and expense of special preparations.
- Hemostatic
- Prevents false union of raw surfaces
- Almost no risk of sensitizing
- Easily kept in place

This is why many surgeons order TUCKS for the patient's bedside.

Please send me sample supply of TUCKS.

of the section of physiology, to the board was confirmed. Retiring members of the staff who were honored at the meeting were Dr. H. E. Essex, co-chairman of the section of physiology; Dr. R. K. Ghormley, senior consultant in and former head of the section of orthopedic surgery; Dr. H. C. Habein, senior consultant in and former head of a section in medicine; Dr. Julia F. Herrick, senior consultant in biophysics; Dr. C. F. Schlotthauer, senior consultant in and former head of the section of veterinary medicine; and Dr. J. F. Weir, senior consultant in and former head of a section in medicine.

Those who joined the staff fifty or more years ago and who were recognized at the meeting were Dr. H. Z. Giffin, fifty-two years ago; Dr. W. F. Braasch, Dr. D. C. Balfour and Dr. W. C. MacCarty, fifty-one years ago; and Dr. G. B. Eusterman and Mr. H. J. Harwick, fifty years ago.

Addresses were given by Dr. Thompson, Dr. Priestley, and Dr. Victor Johnson, director of the Mayo Foundation.

New members of the staff presented were: Drs. L. A. Aaro, consultant in section of obstetrics and gynecology; A. J. Bianco, Jr., consultant in section of orthopedic surgery; E. O. Burgert, Jr., consultant in section of pediatrics; G. D. Davis, consultant in section of diagnostic roentgenology; M. B. Divertie, consultant in section of medicine; D. E. Donald, consultant in section of surgical research; H. N. Huffman, II, consultant in section of medicine; H. K. Ivy, consultant in section of medicine; R. E. Lee, consultant in section of therapeutic radiology; E. M. Litin, consultant in section of psychiatry; D. C. McGoon, consultant in section of surgery; E. A. Moffitt, consultant in section of anesthesiology; J. T. Shepherd, consultant in section of physiology; R. L. Sommerville, consultant in section of medicine; E. H. Soule, consultant in section of surgical pathology; G. B. Stickler, consultant in section of pediatrics; D. C. Utz, consultant in section of urology; R. E. Weeks, consultant in section of medicine; W. H. Weidman, consultant in section of pediatrics.

BLUE EARTH VALLEY MEDICAL SOCIETY

A Fairmont physician, Dr. Harold A. Williamson, was elected president of the Blue Earth Valley Medical Society at the annual meeting in Blue Earth. He replaces Dr. Richard Virnig, Wells. Other officers elected include, Dr. O. B. Bergman, St. James, vice president; Dr. H. Boysen, Madelia, secretary-treasurer; Dr. Mark Vernig, Wells, delegate to the annual meeting of the Minnesota State Medical Association, and Dr. E. E. Zemke, Fairmont, alternate delegate.

RED RIVER VALLEY MEDICAL SOCIETY

The fall meeting of the Red River Valley Medical Society was held at the Rex Cafe in Thief River Falls. Dr. Joseph Kiser, department of surgery, Minneapolis General Hospital, discussed "Positive Staphylococcus Aureus Infections," and demonstrated a new type of

"No patient failed to improve."[1]

pHisoHex washing added to standard treatment in acne produced results that "... far excelled ... results with the many measures usually advocated."[1]

pHisoHex maintains normal skin pH, cleans and degerms better than soap. In acne, it removes oil and virtually all skin bacteria *without scrubbing.*

For best results—four to six washings a day with pHisoHex will keep the acne area "surgically" clean.

surgical mask to reduce these infections in hospitals. Dr. Claude R. Hitchcock, chief, department of surgery of Minneapolis General Hospital, discussed the "Present Status of Surgery for Arterial Disease."

Dr. and Mrs. C. L. Oppegaard, Dr. and Mrs. John Cameron, Dr. and Mrs. Donald Stewart and Dr. R. O. Sather of Crookston attended.

MINNESOTA OBSTETRICAL AND GYNECOLOGICAL SOCIETY

New officers of the Minnesota Obstetrical and Gynecological Society announced recently are Dr. Eugene M. Kasper, St. Paul, president; Dr. Edward A. Banner, Rochester, vice president, and Dr. Alex Barno, St. Louis Park, secretary-treasurer. Dr. Jane E. Hodgson, St. Paul, was elected to a one-year term on the society's Board of Directors to replace the late Dr. Louis L. Friedman of St. Paul. Dr. Harold R. Leland, Minneapolis, was elected to a three-year term.

COURSE IN INDUSTRIAL EYE PROBLEMS

A four-day course in eye care and industrial eye programs will be presented by the Institute of Industrial Health and the Department of Ophthalmology of the University of Cincinnati on March 9-12, 1959. The course will be open to physicians only with preference given to men in active industrial practice. The objective of the course is to furnish the Industrial Physician with up-to-date information regarding eye care in industry.

For additional information and application, write Secretary, Institute of Industrial Health, Kettering Laboratory, Eden and Bethesda Avenue, Cincinnati 19, Ohio.

CONTINUATION COURSES

Medical continuation courses to be presented at the Center for Continuation Study, University of Minnesota, include the following:

January 22-24—Surgery for Surgeons
February 23-25—Cardiovascular Diseases for General Physicians
March 2-4—Pediatrics for General Physicians
March 14—Trauma for General Physicians
March 16-18—Internal Medicine for Internists
March 30-April 3—Basic Concepts of Water and Electrolyte Balance for General Physicians

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14.

"FIGHT ALCOHOLISM DAY" OBSERVED

Governor Orville Freeman proclaimed Sunday, January 18, 1959, as "Fight Alcoholism Day." This was the first time in the history of the state that such a

(Continued on Page A-54)

in corticosteroid therapy of allergic diseases asthma-hay fever allergic rhinitis allergic dermatitis drug reactions

Decadron*

DEXAMETHASONE

to treat more patients more effectively

a new order of magnitude in therapeutic effectiveness
a new order of magnitude in margin of safety

Excellent and good-to-excellent results are reported† with DECADRON in nearly all of 362 patients with various allergic disorders, including a number of cases who had failed to respond to other corticosteroids. **No major reactions** were observed in these extensive clinical studies even after four months of continuous therapy—DECADRON produced no peptic ulcer, no diabetes, no significant hypertension, no sodium retention, no potassium depletion, no edema, no undesirable psychic reactions, and no unusual or new side effects. Less than five per cent of patients experienced minor reactions, none of which prevented continuing administration of DECADRON.

Moreover, several investigators report that side effects induced by previous corticosteroid therapy such as gastric intolerance, peripheral edema, headache, vertigo, muscle weakness, ecchymoses, flushing, sweating, moon facies, hypertension, hirsutism, and acne **often disappeared during therapy with DECADRON.** †Analysis of clinical reports.

Dosage: One 0.75 mg. tablet of DECADRON will replace one 4 mg. tablet of methylprednisolone or triamcinolone, one 5 mg. tablet of prednisone or prednisolone, one 20 mg. tablet of hydrocortisone, or one 25 mg. tablet of cortisone.

Detailed information on dosage and precautions is available to physicians on request.

Supplied: As 0.75 and 0.5 mg. scored, pentagon-shaped tablets in bottles of 100.

"FIGHT ALCOHOLISM DAY" OBSERVED

(Continued from Page A-52)

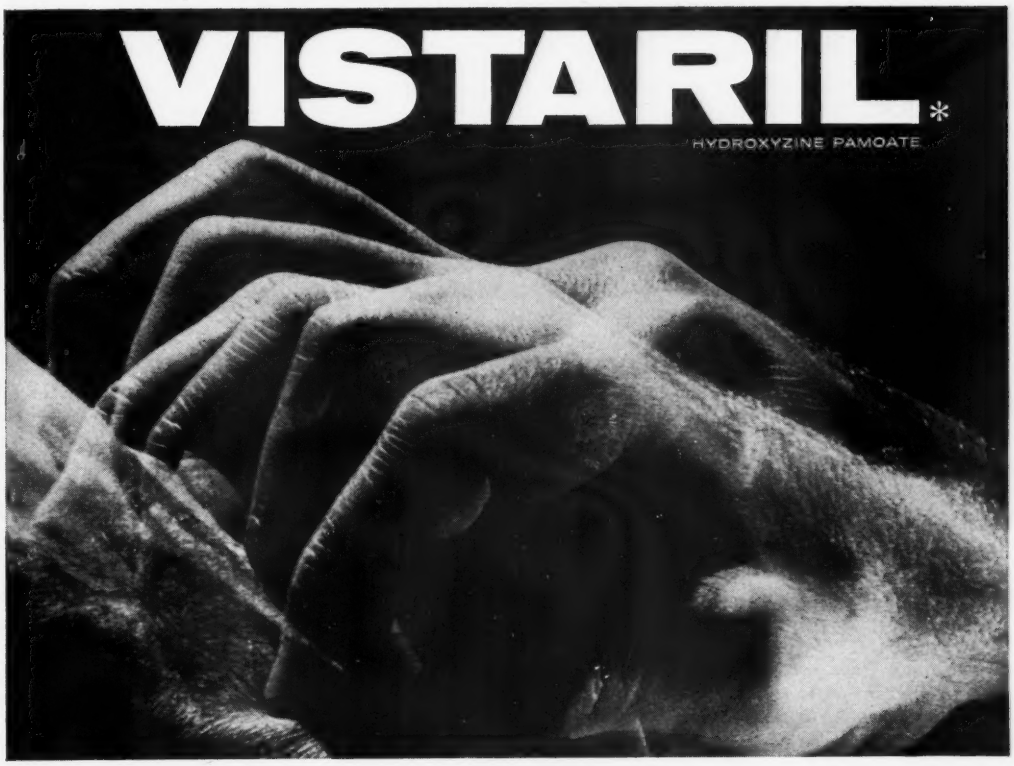
proclamation had been made. The proclamation was put into the charge of the Citizens' Commission on Alcoholism, Inc., that they might spearhead the observance in the state.

Noting that alcoholism is "six times more prevalent than cancer and eleven times more prevalent than tuberculosis," the governor called on the people of Minnesota "to achieve a better knowledge of the causes of alcoholism and the means of combating it so that this social problem can be approached with greater understanding and concern for those afflicted."

Since alcoholism is a difficult problem cutting across many areas such as sociology, religion, local controls, medicine, psychiatry, education and economics, Governor Freeman pointed out that "good home life, pleasant living conditions, better educational opportunities that a fuller appreciation of spiritual values, will eliminate many of the malignancies causing alcoholism."

The Citizens' Commission, in sending out scores of thousands of copies of the proclamation to schools, churches and public institutions call for more sympathetic understanding of the victims of alcoholism, more adequate alcohol education in public schools, more hospital beds available for the ailing alcoholic, more out-patient clinics, and greater efforts in rehabilitation of the alcoholic.

The Commission, being persuaded that the alcoholic is an ailing individual that needs to be helped, has set up counseling centers in many cities, and a rehabilitation clinic in Minneapolis. They publish matters pertaining to alcohol information, conduct research projects, and sponsor seminars for high school young people as well as mass meetings on the adult level. The Citizens' Commission, being a non-profit organization rather than a government agency, is supported wholly by corporate contributions, private and membership donations.



"NAME" ORGANIZED

A group of more than 150 physicians in the Minneapolis-St. Paul area have organized the Northern Association for Medical Education (NAME). The purpose of this organization is to foster the development of a four-year private medical school in St. Paul.

Officers of the organization are: Davitt A. Felder, M.D., President; Edward P. Burch, M.D., Vice President; Ian A. Brown, M.D., Secretary and Ben Sommers, M.D., Treasurer.

Membership in this organization is open to all physicians. Any physician interested in this project and wishing to join the organization, is requested to write to: NAME, 527 Lowry Medical Arts Building, St. Paul 2, Minnesota.

IN URTICARIA AND PRURITUS

A PSYCHOTHERAPEUTIC ANTIHISTAMINE

(as designated by A.M.A. Council on Drugs, 1958)

SPECIFIC ANTIHISTAMINIC ACTION in the treatment of a variety of skin disorders commonly seen in your practice.

"While some of the tranquilizers are only partially effective as far as antiallergic activities are concerned... [hydroxyzine] has been found, by comparison, to be the most potent thus far . . ."[1]

"The most striking results were seen in those patients with chronic urticaria of undetermined etiology."[2]

PLUS

PSYCHOTHERAPEUTIC POTENCY for the relief of anxiety and tension.

The psychotherapeutic effectiveness of hydroxyzine (VISTARIL) was confirmed in a series of 479 patients suffering from a wide variety of dermatoses, including atopic dermatitis, neurodermatitis, psoriasis, lichen planus, nummular eczema, dyshidrosis, pruritus ani and vulvae, and rosacea. "Adverse reactions were minimal."[3]

RECOMMENDED ORAL DOSAGE: *50 mg. q.i.d. initially; adjust according to individual response.*

VISTARIL Capsules: *25 mg., 50 mg., 100 mg.*

VISTARIL Parenteral Solution: *10 cc. vials and 2 cc. Steraject® Cartridges. Each cc. contains 25 mg. hydroxyzine (as the HCl).*

More than a tranquilizer

Woman's Auxiliary

MID-WINTER BOARD MEETING

The board of the Woman's Auxiliary to the Minnesota State Medical Association will hold its mid-year meeting on Monday, February 2, at the Women's City Club, 305 St. Peter Street, St. Paul. The meeting will convene at 9:00 a.m. and will be followed by a luncheon and program. Mrs. Reuben Erickson, State Auxiliary President, urges everyone whose name appears on the state roster to attend.

"It is imperative that every area is represented, so please arrange to have another member of your auxiliary present if you are unable to attend," urges Mrs. Erickson.

STATE AUXILIARY AMA CLINICAL ACTIVITIES

The auxiliary activities of the AMA Clinical Meeting held in Minneapolis, December 2-5, were well attended. On each occasion—the tea at the American Swedish Art Institute Tuesday afternoon, the brunch at Southdale, and the luncheon and tour of General Mills on Thursday —the women felt they were "royally entertained."

Mrs. E. Arthur Underwood, AMA Auxiliary president; Margaret Wolfe, national executive secretary, and Mrs. Charles L. Goodhand, national legislative chairman, were among the eminent guests. Minnesota Auxiliary members attending considered it a great pleasure to meet and become acquainted with these women. A dinner in Mrs. Underwood's honor was given by some of the officers of the local auxiliaries on Monday evening at the Minneapolis Club. More detailed information on the convention will appear in the next issue of *The Gopher Doctor's Wife.*

RANGE AUXILIARY PLANS NEW CODE

Mrs. R. A. Murray has been named chairman of a committee formed by the Range Medical Society Auxiliary to form a new constitution. The society was recently separated from the St. Louis County Medical Society Auxiliary.

Mrs. L. W. Johnsrud, Hibbing, president of the Range Society, appointed the committee. Those serving besides Mrs. Murray are Mrs. Oscar Wilbur and Mrs. L. G. Thouin, Hibbing; Mrs. R. T. Kelly and A. V. Grinley, Grand Rapids; Mmes. R. E. Barnes, Aurora, and C. E. Goodman, Virginia.

RAMSEY COUNTY PAST PRESIDENTS FETED

Past presidents of the Woman's Auxiliary to the Ramsey County Medical Society were guests of honor at a November luncheon meeting. Mrs. John Stuhr, president of the Washington County Auxiliary, was the guest of Mrs. Herman J. Wolff, Ramsey County member and state regional adviser for the Fifth District. Other members of the Washington County Auxiliary were also invited to attend.

The program featured a demonstration of holiday floral decorations. Mrs. Ellery M. James and Mrs. Brian J. McGroarty, chairmen, reported on the auxiliary project to provide transportation for student nurses speaking in local high schools on nursing as a career.

ZUMBRO VALLEY AUXILIARY HEADS ANNOUNCED

New officers and committee chairmen were announced and a talk was given by Miss Madelyne Sturdavant at the November luncheon meeting of the Zumbro Valley Medical Auxiliary at the Rochester Country Club.

Miss Sturdavant talked on the special observation unit at the Rochester Methodist Hospital.

New officers are Mrs. D. C. Dahlin, president; Mrs. O. H. Beahrs, vice president; Mrs. David Hanlon, treasurer; and Mrs. James K. Masson, secretary.

Committee chairmen are Mrs. William Wellman, American Medical Education Foundation; Mrs. G. R. Diessner, cancer; Mrs. J. W. DuShane, legislation; Mrs. James R. Doyle, *Today's Health* magazine; Mrs. G. M. Martin and Mrs. Donald Erickson, membership; and Mrs. H. F. Polley, regional adviser.

HENNEPIN COUNTY AUXILIARY CHRISTMAS LUNCHEON

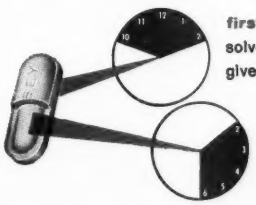
The Christmas luncheon of the Woman's Auxiliary to the Hennepin County Medical Society was held Friday, December 5, at the Interlachen Country Club. Mrs. Frances Miller presented a lovely program of harp music, with a very enlightening and entertaining description of the instrument and its mechanics.

PRESCRIPTIONS

Recent survey disclosed that 90 per cent of the 750 million prescriptions written annually are for medications and products not available even ten years ago according to Dr. Raymond C. V. Robinson, University of Maryland.—*AMA News*

Now—All cold symptoms can be controlled

Provides Triaminic for more complete and more effective relief from nasal and paranasal congestion because of systemic transport to *all* respiratory membranes—without drawbacks of topical therapy.†



Provides well-tolerated APAP (N-acetyl-p-aminophenol) for prompt and effective analgesic and antipyretic action to make the patient more comfortable.

Provides Dormethan (brand of dextromethorphan HBr) for non-narcotic antitussive action on the cough reflex center in the medulla—as effective as codeine but without codeine's drawbacks.

Provides terpin hydrate, classic expectorant to thin inspissated mucus and help the patient clear the respiratory passages.

†Lhotka, F. M.: Illinois M. J. 112:259 (Dec.) 1957. Fabricant, N. D.: E. E. N. T. Monthly 37:460 (July) 1958. Farmer, D. F.: Clin. Med. 5:1183 (Sept.) 1958.

Special "timed release" design

first—the outer layer dissolves within minutes to give 3 to 4 hours of relief

then—the inner core releases its ingredients to sustain relief for 3 to 4 more hours

also available for those patients who prefer liquid medication: Tussagesic suspension

Each TUSSAGESIC tablet provides:

TRIAMINIC®	50 mg.
(phenylpropanolamine HCl	25 mg.
pheniramine maleate	12.5 mg.
pyrilamine maleate	12.5 mg.)
Dormethan (brand of dextromethorphan HBr)	30 mg.
Terpin hydrate	180 mg.
APAP (N-acetyl-p-aminophenol)	325 mg.

Dosage: One tablet in the morning, midafternoon and in the evening, if needed.

Tussagesic® *timed-release tablets*

**Contains* TRIAMINIC *to* STOP *running noses*   *and open stuffed noses orally*

In Memoriam

HOMER P. DREDGE

Dr. H. P. Dredge, prominent pioneer resident of Sandstone, died at the Asbury Hospital, Minneapolis, November 27, 1958. He had spent the past year with his children in Minneapolis. He was eighty-eight years of age at the time of his death.

Homer Percy Dredge was born in Blue Earth County, Minnesota, August 4, 1870. He graduated from the Mankato State Teachers Normal School in 1893 and from the Rush Medical College in 1896. He practiced medicine at Belview from 1896 to 1903 and the family came to Sandstone in 1903.

He took an active lead in all community activities. He was instrumental in helping to secure the former Federal Correctional Institution at Sandstone, which at the present is used as a State Mental Hospital. He was also instrumental in promoting a County Hospital to be located at Sandstone and his dream was realized with the erection of the twenty-five-bed Pine County Memorial Hospital.

In 1955, the Hartley M. Robey American Legion Post of Sandstone sponsored the Sandstone Hall of Fame, and Dr. Dredge was selected to be honored at a Hall of Fame dinner held July 16, 1955. Funds from the Hall of Fame project were used to furnish the waiting room as a memorial to Dr. Dredge, in the new Pine County Memorial Hospital.

Dr. Dredge served as Sandstone health officer for more than forty-five years. He was a member of the school board thirteen years, was Past Master of the Sandstone Masonic Lodge, member of the Eastern Star and Odd Fellow Lodges, past trustee of the Congregational Church, life member of the Sandstone Chamber of Commerce.

On January 22, 1948, Dr. and Mrs. Dredge celebrated their golden wedding anniversary. Mrs. Dredge passed away January 21, 1956.

In 1955, Dr. Dredge was granted a life membership in the Minnesota State Medical Association. He held memberships in the Pine County, East Central and Hennepin County Medical Societies.

Surviving are three daughters, Ethel Dredge, Florence (Mrs. Earl Lyons) of Minneapolis, and Alice (Mrs. Paul Wylie) of Bozeman, Montana; three sons, Dr. Thomas Dredge, Tomah, Wisconsin; Homer Dredge, Waverly, and Robert Dredge, Richfield. He is also survived by one brother, George, Minneapolis, and three sisters, Marion Thorne and Stella Lombard in Florida and Jessie Barnes, Vernon Center, Minnesota.

LEE McKENDREE EATON

Dr. Lee McKendree Eaton, chairman of the sections in the Mayo Clinic and professor of neurology of the Mayo Foundation, died November 18, 1958, at the Methodist-Worrall Hospital in Rochester after a short illness.

Dr. Eaton was born at Owaneco, Illinois, on February 3, 1905. He received his M.D. degree from Rush Medical College, Chicago, in 1932, and served an internship in the Cook County Hospital. He became a Fellow in neurology in the Mayo Foundation in 1933 and a consultant in neurology on the staff of the Mayo Clinic in 1936.

Dr. Eaton was a Fellow of the American Academy of Neurology, a member of the advisory board of the Myasthenia Gravis Association and the American Neurological Association. He was president of the Central Neuropsychiatric Association in 1953. In addition, he was a member of the Association for Research in Nervous and Mental Diseases of which he was president at the time of his death, the Alpha Omega Alpha honorary medical society, a director of the American Board of Neurology and Psychiatry (examiner) and a member of Nu Sigma Nu. Dr. Eaton was a member of the Zumbro Valley Medical Society, the Minnesota State Medical Association and the American Medical Association.

Nonvocational organizations of which Dr. Eaton was a member include the Society of Sigma Xi and the Universalist Church of America. His hobbies were photography, horticulture, boating, hunting and fishing, and Mississippi River lore.

Survivors include his wife, Mary Louise, and five children: Elizabeth B. (Mrs. Eugene D. Monson), of Minneapolis; Lynne S., Emily J., Charles M., and Thomas L., of Rochester, and one grandchild, William E. Monson.

FRANK R. HIRSHFIELD

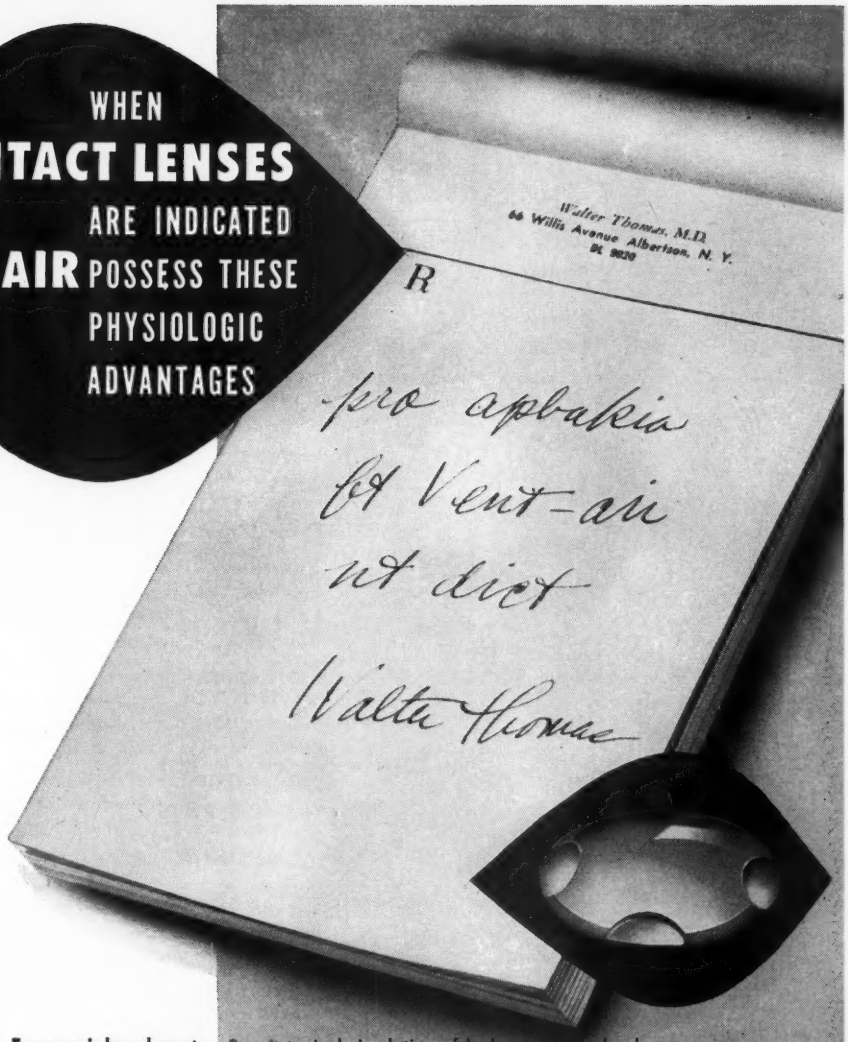
Dr. Frank R. Hirshfield, St. Louis Park physician and surgeon, died December 16, 1958. He was sixty-four years of age at the time of his death.

Specializing in the industrial practice of medicine, Dr. Hirshfield also operated the Hirshfield paints and wallpaper stores in Minneapolis.

Dr. Hirshfield was born in Minneapolis and received his preliminary education in St. Thomas High School and the University of Minnesota. His medical education was obtained at the University of Minnesota Medical School.

He was a staff member at Eitel and Minneapolis General Hospitals, and was also a member of the Hennepin County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was a member of Minneapolis Masonic Lodge No. 19.

He is survived by his wife, Ruth; a son, Frank; a daughter, Mrs. Kenneth Heidelberg, and his mother, Mrs. Elizabeth Hirshfield, all of Minneapolis.



WALTER F. MUIR

Dr. Walter F. Muir, Browns Valley physician, died December 12, 1958. He was fifty years of age at the time of his death.

Dr. Muir graduated from the University of Minnesota Medical School in 1933 and practiced in Graceville, Minnesota, prior to service with Army Medical

WHEN
CONTACT LENSES
ARE INDICATED
VENT-AIR POSSESS THESE
PHYSIOLOGIC
ADVANTAGES

Four peripheral vents	Permit topical circulation of lachrymal and glandular secretions without excessive motility
Corneal apical clearance	Favors normal corneal metabolism and oxygenation
Ultra-Smoothness of Inner and Outer Surfaces	Avoid limbal epithelial and tarsal conjunctival exacerbation
Highly absorptive methyl-methacrylate composition	Simulates "wetting" and moisture-retention properties of cornea (of military specification)
Precision-ground	Prescriptive qualities exact to ± 0.12 D. with precise allowance for vertex refraction and lachrymal factor (exact to .02 mm radius in inner curvature)
Custom-fitted	In uni-, bi-, or tri-curve radii conforming to corneal peripheral asphericities
Hyper-thinness of edge or center	Maintains uniform thickness in high myopia or hyperopia approximating .20 mm irrespective of power
Widest range of inner radii	From 5.0 to 10.00 mm providing for extremes of keratoconic and megaloglobic dimensions
Cosmetic, pin-hole and tinted effects	For leucomatous, polyopic, iridodialytic and albinic conditions or other corneal or media anomalies.

Corps in World War II. Since 1946, he had practiced in Browns Valley.

He was a member of the West Central Minnesota Medical Society, the Minnesota State Medical Association, the American Medical Association, Psi Upsilon fraternity, Nu Sigma Nu medical fraternity, and William Krersing American Legion post in Browns Valley.

Survivors include his wife, Candace; two sons, Edwin and Robert, both of Browns Valley; two sisters, Mrs. Joseph R. Watkins, Winona, Minn., and Mrs. Donald F. McConnon, Minneapolis; and a brother, Dr. Edwin C., Tacoma, Washington.

EDWIN J. SIMONS

Dr. Edwin J. Simons, Executive Director of Minnesota Blue Shield and one of the founders of that organization, died December 11, 1958. He was sixty-two years old.

A former president of the Minnesota State Medical Association, Dr. Simons had practiced at Swanville, Minnesota, for twenty-five years before becoming medical director of Blue Shield in 1950.

He graduated from the University of Minnesota Medical School and received a distinguished alumni award in 1956.

In addition, he was a member of the Hennepin County Medical Society, Minnesota State Medical Association, and the American Medical Association. He was also a member of the Masons, the American Legion, and was a fellow of the American College of Physicians.

Surviving are his wife, Hazel C.; a son, Jack Scott; a daughter, Galen Claire, all of Edina; three brothers, Dr. John B. and H. R. Simons, both of Whitefish, Mont., and Thomas W. Simons, Madras, India; three sisters, Mrs. Julia Westling, Minneapolis, Mrs. Irene Allen, Greenbush, Minnesota, and Mrs. Mary Johnston, Frankfurt, Germany.

A workhorse "mycin" for common infections

respiratory infections

prompt, high blood levels

consistently reliable and reproducible blood levels

minimal adverse reactions

With well-tolerated CYCLAMYCIN, you will find it possible to control many common infections rapidly and to do so with remarkable freedom from untoward reactions. CYCLAMYCIN is indicated in numerous bacterial invasions of the respiratory system—lobar pneumonia, bronchopneumonia, tracheitis, bronchitis, and other acute infections. It has been proved effective against a wide range of organisms, such as pneumococci, H. influenzae, streptococci, and many strains of staphylococci, including some resistant to other "mycins." Supplied as Capsules, 125 and 250 mg., vials of 36; Oral Suspension, 125 mg. per 5-cc. teaspoonful, bottles of 2 fl. oz.

Minnesota Blue Cross—Blue Shield

The Minnesota Blue Shield Professional Relations Staff made 5,764 calls at doctors' offices throughout the state during the first eleven months of 1958, and over 1,350 calls resulted in personal visits with doctors.

The aim of the professional relations program, which is service to the medical profession and the public, is best served by personal calls to doctors' offices by professional relations representatives. Much can be accomplished, even though those calls do not result in personal visits with doctors, because certain Blue Shield matters should also be discussed with office employes.

For example, they are offered assistance on how to complete medical service reports briefly yet effectively resulting in more rapid payment by Blue Shield and less correspondence between doctors' offices and Blue Shield.

Other activities of the professional relations program aimed at providing service to physicians include correspondence and telephone information, news releases, and the quarterly bulletins.

Correspondence and telephone information are equally important where subscribers are concerned, for if subscribers receive ample information from Blue Shield regarding the coverage provided by the contracts and other matters, fewer inquiries will be directed to doctors and their office personnel.

Many of the professional relations activities for 1959 have already been planned on the basis of better service to the medical profession through every phase of the professional relations program.

During 1958, the Blue Cross Hospital Relations Department carried out its hospital relations program through various media.

Visits were made to the Blue Cross contracting hospitals to discuss whatever problems might exist between the hospitals and Blue Cross. Every Blue Cross hospital in Minnesota but one was visited personally, and Blue Cross was discussed with every hospital administrator in Minnesota or with responsible people in the hospital.

Meetings were held with a number of hospital boards to discuss the Blue Cross Plan and the hospital's Blue Cross experience.

Member Blue Cross hospitals were invited to hold one of their Board meetings at the Blue Cross office. Two Blue Cross member hospitals, St. Luke's and St. John's, both of St. Paul, held one of their monthly Board meetings at the Blue Cross office, and an educational program on Blue Cross was provided as a part of their Board meeting.

Area meetings were arranged and held for hospital bookkeeping personnel. Two of these meetings were held and so successfully that more meetings of this type are planned for the future. These meetings dealt primarily with the technical problems of Blue Cross coverage and clearance of Blue Cross cases and benefits.

A hospital relations representative attended the district meetings of the Minnesota Hospital Association carried out in various Hospital Association districts in the state, in all instances where Blue Cross was invited to attend. The Blue Cross representative in several instances participated in the meeting and gave a discussion of Blue Cross matters as a part of the program.

Negotiations were carried on with all of the new general hospitals constructed in the state of Minnesota and opened during 1958. Each of these hospitals either requested inclusion in the Blue Cross Plan and was included as a member hospital after completion of the routine requirements and contracts; or is in the process of being included in the Blue Cross Plan upon completion of the necessary requirements and contracts.

Women see physicians more often than men do, especially at the ages of 15 through 44. During childhood, however, boys receive more medical care than girls.

Persons in low-income groups now see a physician almost as often as those in high-income groups, says Health Information Foundation. Thirty years ago, by contrast, high-income families averaged about half again as many visits to doctors as did those with the lowest incomes.

—Health Information Foundation.

even when the causative organism may be a "persistent staph"

Cosa-Signemycin*

GLUCOSAMINE-POTENTIATED TETRACYCLINE WITH TRIACETYLOLEANDOMYCIN

increases the certainty of safe, rapid response

AS PROVED BY extensive clinical trials—an over-all success rate of more than 94% was achieved in a total of 3,280 cases.†

AS PROVED BY success in mixed infections—more than 95% of 1,000 acute and chronic respiratory tract infections were successfully treated; a 99% cure rate was achieved in mixed bacterial pneumonias.†

AS PROVED BY effectiveness in "problem infections"—a response rate better than 96% was recorded in a group of 221 gastrointestinal infections including chronic intestinal amebiasis; 91% of 465 urogenital infections were successfully controlled.†

AS PROVED BY excellent safety record—extremely well tolerated; discontinuance of medication was necessary in only 11 of 3,280 patients.†

A significant number of the above cases had not responded to other antibiotics.

Cosa-Signemycin is particularly valuable in home and office, where susceptibility testing is difficult or impractical.

SUPPLY: *Capsules* (green and white), 250 mg. and 125 mg.
New Oral Suspension (raspberry-flavored), 2 oz. bottle, 125 mg. per teaspoonful (5 cc.).
New Pediatric Drops (raspberry-flavored), 10cc. bottle, 5 mg. per drop, plastic calibrated dropper.

Average dosage: For adults, 1-2 Gm. daily in divided doses; proportionately less for children, depending on age, weight, and severity of infection.

†Literature and bibliography available on request.

General Interest

Dr. John R. Watson, member of the Olmsted Medical Group, was a recent speaker at a meeting of the Minnesota Obstetrical and Gynecological Society at Mayo Memorial Building in Minneapolis. Dr. Watson's topic was "The Use of Pharyngeal Airway in Premature Breech Delivery."

* * *

The Lake Region Clinic, located previously in the Penney Building, Detroit Lakes, has moved to its new home at 1135 Washington Avenue. Members of the Clinic are **Dr. William C. Dodds, Dr. Virgil A. Watson** and **Dr. Robert N. Watson.** The new building, modern in every detail, covers an area of 4,000 square feet and twenty-two rooms including two waiting rooms. The structure is fully air conditioned and has sound-proof rooms including a lead-lined x-ray room.

Three St. Cloud doctors have begun development of a two-acre tract of land near the airport entrance to be known as "Doctor's Park." Plans are to sell lots for office buildings for doctors, dentists, architects, lawyers, and other professional people. **Dr. William A. Autrey** is associated with **Dr. Henry J. Reif** and **Dr. C. F. Brigham, Jr.,** in the project. Two buildings presently are under construction in the area—one is owned by Drs. Autrey, Reif and Brigham. The other is being constructed by **Dr. Edward M. LaFond.** Dr. Autrey said he and his associates have a five-year option on three adjoining acres of land from the Whitney Land Company, to be developed for the same purposes. The building to be occupied by the associates will contain space for eighteen examining rooms, offices, laboratories, and reception rooms. Dr. LaFond is constructing a three-office building.

* * *

Dr. Robert Cullen, Evansville, Indiana, will be associated with **Dr. John Watkins** in the practice of medicine at the Dr. Watkins Medical Clinic.

* * *

The new hospital at Tyler has been named the **Dr. A. L. Vadheim** Memorial Hospital by action of the Tyler village council. Dr. Vadheim started a five-bed hospital in 1915. It was destroyed by a cyclone in 1918. A second hospital was set up in 1920 and another addition was made in 1938.

* * *

Dr. Morton Roan, former Lamberton and Anoka physician, has established a practice in Ellendale, Minnesota.

* * *

Dr. J. T. Priestley, chairman of the Board of Governors of the Mayo Clinic, head of a section of surgery and professor of surgery in the Mayo Foundation, has been elected president of the Western Surgical Association. He succeeds Dr. James Barrett Brown,, St. Louis surgeon. **Dr. Deward O. Ferris,** a Mayo Clinic staff member, was elected first vice president, succeeding Dr. Philip B. Price, Salt Lake City, Utah. **Dr. O. H. Beahrs,** a member of the Mayo Clinic staff, was elected to membership in the Western Surgical Association. He is head of a section of surgery in the Mayo Clinic and assistant professor of surgery in the Mayo Foundation.

* * *

New Ramsey County Medical Society officers are **Dr. Gordon Kamman,** president; **Dr. Abbott Skinner,** secretary-treasurer; **Dr. Walter Gardner,** president-elect, and **Dr. E. V. Kenefick,** vice president, all from St. Paul.

* * *

Dr. Gordon C. MacRae, Duluth physician and surgeon, has been appointed medical director of the Duluth Rehabilitation center under an annual $5,000 grant from the Sister Elizabeth Kenny Foundation.

* * *

A former Northfield and Roseville physician and surgeon, **Dr. W. G. Larson,** has announced the opening of an office for the practice of medicine in the Kinne Building, 8488 Central Avenue in Spring Lake Park.

* * *

"Safeguarding Our Health" was the topic of an address presented by **Dr. Elizabeth Mussey** of the Mayo Clinic at a recent meeting of the Business and Professional Women's Club in Rochester.

* * *

Dr. J. Arnold Bargen, Rochester, was recently named vice president of the Mississippi Valley Medical Society at that group's annual meeting in Minneapolis.

* * *

Dr. Carl A. Schwartz, former chief of psychiatry at the Anoka State Hospital, has been named psychiatrist for the Mower County Health Clinic.

* * *

The undernoted physicians have been appointed to the medical staff of the Cloquet Community Memorial Hospital. **Drs. John M. Streitz, Kenneth A. Storsteen, Malcolm M. Fifield, John H. Peterson, Thomas O. Young, Robert J. Deutsch, James S. Spang,** and **William M. Spang,** all of Duluth.

* * *

Dr. G. W. Clifford, of the Alexandria Clinic, recently attended an intensive review course in surgery at the Cook County Graduate School of Medicine in Chicago.

* * *

The St. Cloud Medical Group **(Drs. P. L. Halenbeck, R. T. Petersen** and **C. B. Thuringer)** recently moved to its new office building. Two physicians, **Dr. Richard F. Kline** in internal medicine and **Dr. Anthony T. Rozycki** in obstetrics and gynecology, are recent additions to the group.

* * *

Elected recently to the American Academy of Child Psychiatry is **Dr. Jack V. Wallinga,** Minneapolis psychiatrist.

* * *

Dr. John F. Briggs, St. Paul internist and member of the Minnesota Heart Association's executive committee,

spoke to members of the Twin City Coronary Club at its fourth orientation lecture recently. The group is composed of persons who have recovered from heart attacks and returned to normal activities. Members, through physician referrals and with clerical assistance from the Minnesota Heart Association, offer a visiting service to coronary thrombosis victims. Memberships are still available for men and women. Anyone interested in joining should call the Heart Association, MIdway 6-6553.

* * *

Dr. George S. Baker, of the Mayo Clinic medical staff, was elected president of the American Academy of Neurological Surgery at a meeting in Toronto, Ontario. Attending the Toronto meeting with Dr. Baker were **Drs. N. P. Goldstein, N. C. Hill, H. J. Svien, H. R. Terry,** and **Alfred Uihlein.**

* * *

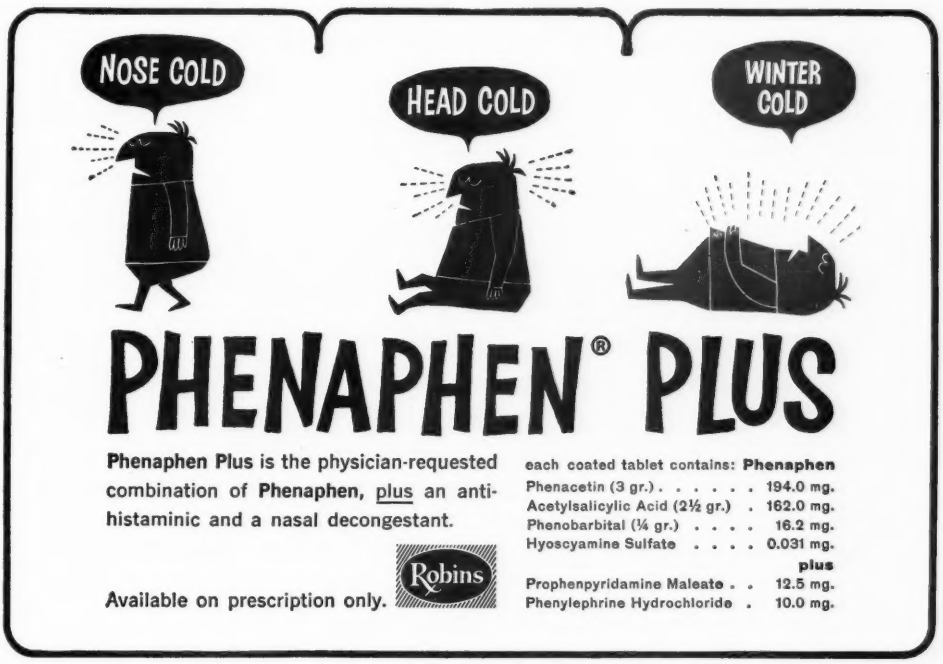
Consulting psychiatrist of the Willmar Mental Health Clinic is **Dr. George Dorsey.** Other members of the team are **Dr. P. V. Mehmel,** clinical psychologist, and **Elwyn Wenger,** psychiatric social worker.

* * *

Dr. G. Keith Stillwell, Rochester, has been named president of the Minnesota Rehabilitation Association. Elected members of the advisory board were **Dr. Glenn Gullickson,** Minneapolis, and **Dr. Frank H. Krusen,** Rochester.

Dr. Henry Woltman, retired head of the section of neurology and psychiatry at the Mayo Clinic, who is now in neurology at Rochester State Hospital, was one of about twelve neurologists and neuro-physiologists selected by the U. S. Public Health Service to make a month-long observation trip to Russia. The group will study various Russian institutes of research and training and will also give lectures.

* * *



An institute for public health nurses on common emotional problems of school-age children was held December 4-5 at the University of Minnesota Center for Continuation Study. Chief resource person was **Dr. Paul F. Wilson,** director of the mental health clinic, Rochester-Olmsted County Health Center. Dr. Wilson discussed needs and feelings of school-age children, and the problems which may arise.

* * *

Dr. Albert V. Stoesser was guest speaker at the fall meeting of the Tri-County Society (Eau Claire-Dunn-Pepin Medical Society) held at Menomonie, Wisconsin, November 22, 1958. The subject of his talk was "The Proper Handling of the Allergic Manifestations in Infancy and Childhood."

ULMER

LABORATORY REAGENTS and stains

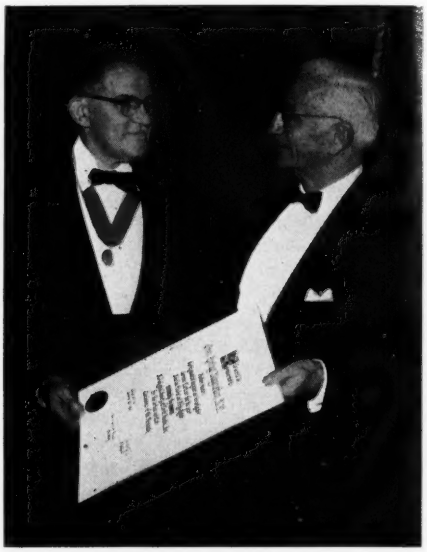
New CATALOG

If you haven't already received your free copy of our new 64 page catalog of clinical Reagents and Stains, write for same today. It lists all of the more commonly used laboratory reagents and stains. You will find it very helpful.

ULMER REAGENTS AND STAINS HELP ACHIEVE ACCURACY

It is our objective to produce the finest reagents obtainable for clinical laboratory use. Their consistent accuracy saves hours of the technician's time.

Our scientific laboratory control is your assurance that Ulmer reagents are always fresh and meet the most exacting standards for each procedure. Every step of the manufacturing process is checked from the raw materials to the finished product. Moreover, our chemists are available to assist with any procedures with which you may be experiencing difficulties. Do not hesitate to call on them for assistance or advice.



For prompt and efficient service as well as guaranteed satisfaction, insist on Ulmer Reagents and order them direct from P & H.

most meritorious contribution to Clinical Pathology at the recent meeting of the American Society of Clinical Pathologists. He delivered the Ward Burdick lecture on "The Antigen of Echinococcus."

* * *

Dr. Owen H. Wangensteen *(right)* Minneapolis, Professor of Surgery, University of Minnesota School of Medicine, received a scroll commemorating his Carman Lecture at the 44th annual meeting of the Radiological Society of North America, November 16-21, 1958, in Chicago. Dr. Leo G. Gigler, Los Angeles, California, Society President, is shown extending congratulations. Dr. Rigler formerly was a colleague of Dr. Wangensteen's at the University of Minnesota before moving to Los Angeles. The Carman Lecture is the scientific highlight of the Radiological Society's annual convention. Dr. Wangensteen's topic for the 1958 Lecture was "Carcinoma of the Stomach."

* * *

Dr. Raymond D. Pruitt, consultant in medicine in the Mayo Clinic, Rochester, Minnesota, and professor of medicine in the Mayo Foundation, Graduate School, University of Minnesota, has been appointed secretary of the Minnesota Rhodes Scholarship Selection Committee. This committee will interview Minnesota candidates for Rhodes scholarships.

The average person today sees his doctor about five times a year, Health Information Foundation reports. In the aggregate, Americans use between 800 and 850 million physician visits a year.

Communications

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

RECALCITRANT UNIT AT ANOKA

On October 29, 1958, the Minnesota Department of Welfare announced the availability of the Recalcitrant Unit at the Anoka State Hospital, for caring for irresponsible people with active tuberculosis who by their conduct endanger the health of others. The philosophy and procedures for admission of patient to the Unit were described in a Memorandum from the Department.†

In summary, any health officer may report his knowledge of a recalcitrant tuberculosis case to the board of county commissioners or the District Court. Through the board or the court, such recalcitrant person may be given a fair hearing and committed to a designated tuberculosis sanatorium, including the Recalcitrant Unit. If necessary, the recalcitrant patient may be admitted to the Anoka State Hospital, upon making arrangements with the Superintendent, and kept there as long as necessary.

Physicians and others concerned with cases of tuberculosis who may be endangering the public's health may wish to know of this development. For further information about procedures, the physician should consult his local or state health department, tuberculosis sanatorium, the State Department of Welfare, or the Anoka State Hospital.

MINNESOTA MEDICINE—FIRST

In reply to your letter of November 20, 1958, following is a report for MINNESOTA MEDICINE:

January through October, 1958 (ten months' net revenue $52,231.15)—percentage gain over same period of 1957 is 40.2 per cent.

The average gain for the thirty-three journals we serve is 23.9 per cent. MINNESOTA MEDICINE has enjoyed the highest gain of any of our publications; none of them have an average above 29 per cent gain. This is fabulous since no other medical journal can report the increase outlined above.

I cannot make a prediction for 1959, since many advertising schedules have not been released to date. I do expect we shall hold 1957 billing figures and possibly 1958 figures.

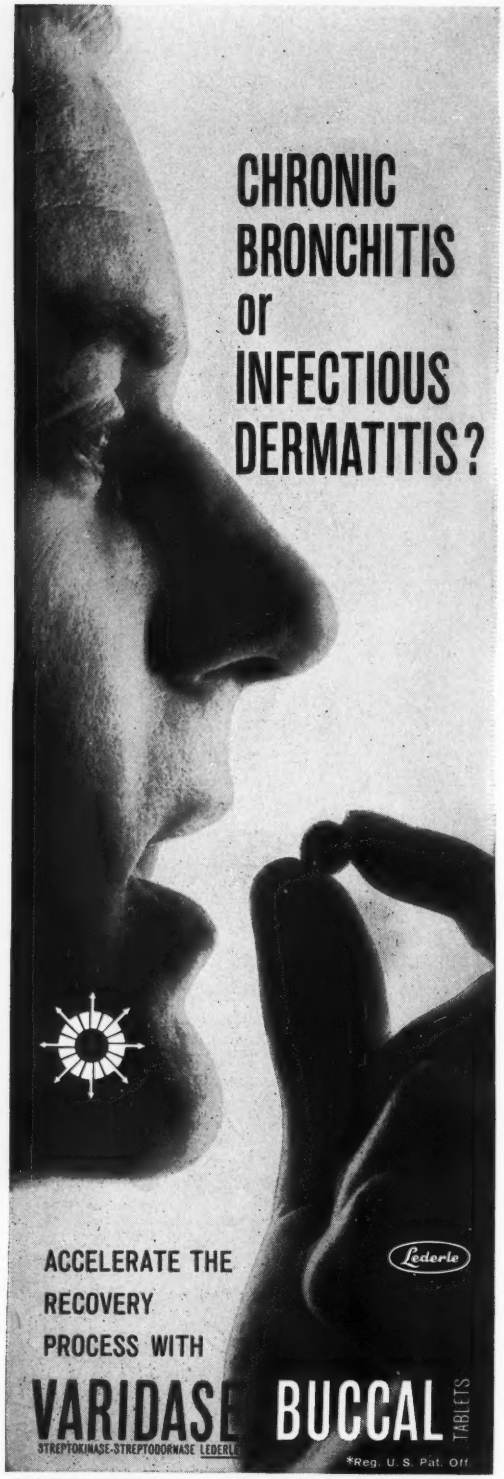
Sincerely yours,
ALFRED J. JACKSON, President
State Medical Journal Advertising Bureau, Inc.

For active mothers-to-be

Ulvical® (Ulmer) assures these modern ladies-in-waiting of a generous amount of iron and calcium plus the recognized prenatal vitamins . . . in a small tablet . . . especially designed for rapid assimilation and easy toleration.

For maximal utilization . . . timed release of these essentials is accomplished by special coatings controlled to dissolve at the pH of the stomach, duodenum and jejunum.

Important, too, calcium pyrophosphate contains larger amounts of elementary calcium which is quickly metabolized to increase plasma blood levels. Leg cramps are quickly relieved; small daily doses sustain this relief.



Each tablet contains:

Calcium Pyrophosphate (Ca 150 mg., P 120 mg.), 7½ gr.
Ferrous Sulfate USP (Fe 38 mg.) 3 gr. 3.8 M.D.R.
Vitamin A (Ester) 1500 USP Units ⅜ M.D.R.
Vitamin D (Irradiated Ergosterol) 200 USP Units ½ M.D.R.
Thiamine Mononitrate (B_1) 1 mg. 1 M.D.R.
Riboflavin (B_2) . . . . 2 mg. 2 M.D.R.
Ascorbic Acid (C) 16.66 mg. ½ M.D.R.
Vitamin E . . . . . 2.2 I.U.* (from d alpha tocopheryl acetate N.F.)
M. D. R. — Minimum Daily Requirement. *M.D.R. not established.
Dose: One or two tablets three times a day.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

A DOCTOR SPEAKS HIS MIND. By Roger I. Lee. 120 pages. Portrait. Boston and Toronto: Little, Brown and Company, 1958. Price, $3.00.

Dr. Lee records his thoughts and philosophies concerning many matters in this little volume. His writing style is simple and direct. The subjects are interesting and his comments to the point. The book can be recommended for pleasant reading.

JOHN F. BRIGGS, M.D.

RADIOACTIVE ISOTOPES IN CLINICAL PRACTICE. By Edith H. Quimby, Sc.D., Sergei Feitelberg, M.D., and Soloman Silver, M.D. Philadelphia: Lea & Febiger, 1958. 451 pages. Price $10.00.

This book is commendable for its lucid arrangement into three major divisions on basic physics, instrumentation, and clinical applications; and, a logical breakdown of these again into numerous subheadings. The author of the first portion is this country's most distinguished interpreter of radiation physics, Dr. Edith Quimby. Her discrimination between what is and is not important is founded on many years of teaching the subject to physicians as well as examining candidates who appear before the American Board of Radiology. Some of the subjects treated are: fission, production of radioisotopes, nuclear reactions, modes of radioactive decay, interaction of radiation and matter, and radiation hazards. There is an important chapter on dosage calculation which, unfortunately, is too complex for the average physician to comprehend completely.

In the second portion, Feitelberg describes the different methods of detecting and measuring radiation, with the special problems involving various beta and gamma emitters inside and outside the body. He warns against certain assumptions on the part of beginners which will lead to erroneous results.

The third portion makes no attempt to be encyclopedic, but, in the words of the author, is limited to "those isotopes and their applications which actually are being used in medical practice and have a demonstrated usefulness." Different isotope-users are apt to interpret this thesis differently; but, in general, Silver displays admirable restraint. It is important for a writer on this subject to avoid undue enthusiasm for procedures which turn out to be mere novelties. The use of radio-iodine in thyroid disorders is thoroughly discussed on the basis of many years' experience. The fascinating fact of erroneous high uptake by the thyroid, which is bound to stump every isotopist sooner or later, is explored and explained. The author might have been more critical

of isotope cardiac output studies and of results claimed for treatment of carcinomatous effusions with radiogold.

There are now six contemporary American textbooks in the field of nuclear medicine. The brevity and clarity of this volume makes it particularly satisfying both for teaching the fundamentals of the subject and as a reference.

ELMER C. PAULSON, M.D.

MICRODIFFUSION ANALYSIS AND VOLUMETRIC ERROR, 4th Ed. By Edward J. Conway. 466 pages. Price, $8.50. New York: The Macmillan Company, 1958.

Written for laboratory analysts and technicians, chemists and biochemists, medical technicians, clinicians and pharmacists, students and teachers, this is a necessary book for every analyst's laboratory and a source of ideas for all interested in accurate small-scale analysis. An up-to-date and vastly improved edition of a classic work, it includes a section on apparatus and principles used in microdiffusion analysis, an account of laboratory methods, and a new treatment of volumetric error with particular reference to micro-quantities.

• Here's what the general practitioner has been waiting for. This is a review of symptomatology and methods of diagnosis which helps simplify the virus disease problem. Congratulations to Dr. Kleinman and the Minnesota Department of Health.

Current Virus Disease Problems In Minnesota

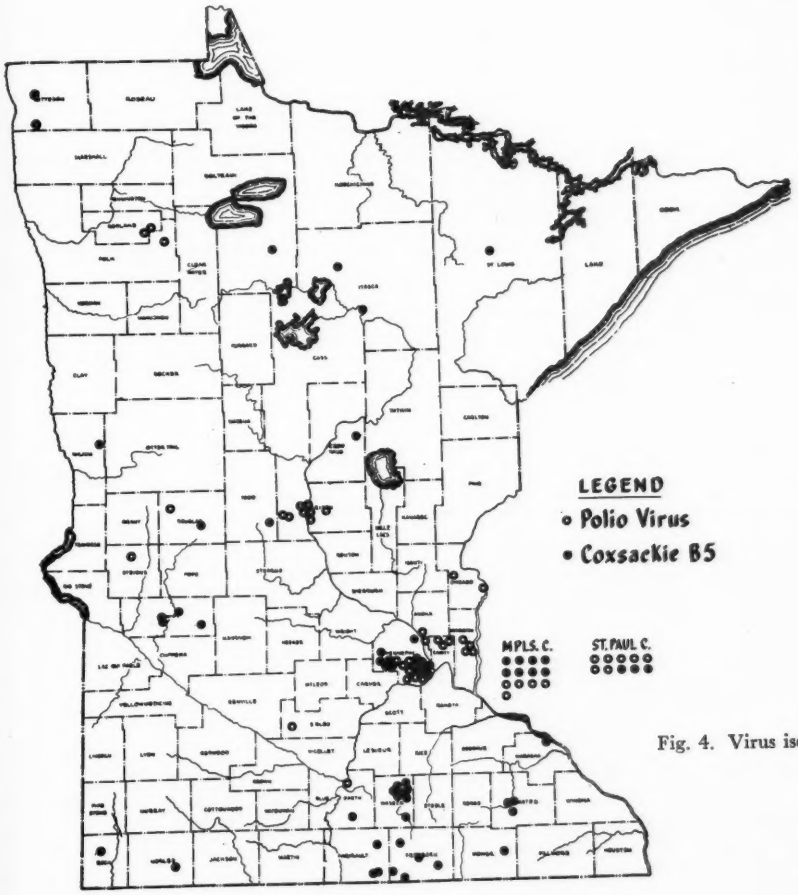

Fig. 4. Virus isolations, Minnesota, 1956.

HERMAN KLEINMAN, M.D.
Minneapolis, Minnesota

Dr. Kleinman is Chief, Section of Chronic Diseases, Minnesota Department of Health.

IN the broadest sense, all virus diseases are of some current interest; if not because of high incidence, then because of other important aspects. Rabies and poliomyelitis are examples of virus diseases where immunization procedures are of current importance because of new concepts and new procedures. Influenza has been of current

Presented at the Annual Meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 23, 1958.

interest because of a recent epidemic due to a new, the Asian, strain, and also because of the immunization problem involved.

However, the greatest sustained interest rests with those diseases associated with the family of viruses known as the enteroviruses. This field is moving fast because of the refinement and expansion of tissue culture techniques. Minnesota in the past three years has for each separate year had experience with diseases similar in symptomatology, but in each instance due to a different virus. This family of viruses and the human diseases with which they are associated are listed in Table I. It should be noted that there is no group in this family in which some types have not been implicated in the aseptic meningitis syndrome. In addition, ECHO virus types 4, 9, and 16, have been associated with summer exanthematous disease.[1,2]

TABLE I. ASSOCIATION OF ENTEROVIRUSES WITH HUMAN DISEASE

Enteroviruses	Associated Disease
Poliovirus	Paralysis (complete to slight muscle weakness) Aseptic meningitis Undifferentiated febrile illness, particularly during the summer
Coxsackie viruses, Group A	Herpangina Undifferentiated febrile illness, particularly during the summer Aseptic meningitis (Types A7, A9)
Coxsackie viruses, Group B	Aseptic meningitis Pleurodynia Myocarditis or encephalomyocarditis during neonatal period and early childhood Mild paralysis (?)
ECHO viruses	Aseptic meningitis (Types 2, 3, 4, 5, 6, 9, 14, 16) Summer rash (Types 4, 9, 16*) Summer febrile illness Mild paralysis (?) (Type 6) Summer diarrhea of infants and children (Type 18 and others)

*Neva has found the etiologic agent of Boston exanthem to be antigenically related to ECHO virus Type 16.

It should be understood at this point that the term *aseptic meningitis* is used in its presently accepted sense. That is, the term applies not to a specific disease entity but represents a syndrome common to many etiologies. The most characteristic symptoms and signs of this syndrome are fever, headache, nuchal rigidity, back rigidity, and changes in the cerebrospinal fluid consisting of a pleocytosis with the lymphocyte as the predominant cell. The responsibile agents include both bacteria such as the tubercle bacillus and leptospirae as well as a variety of viruses. It is the latter group, the viruses, which will be considered here. The term, too, is overcoming some of its early unsavory reputation as a diagnostic wastebasket mainly because recent work in virus laboratories has enabled some groups of this syndrome to be lifted out of the "etiology undetermined" class. It is apparently respectable to be called aseptic meningitis if the parents are known. The diagnosis of ECHO 9 aseptic meningitis has as much nosologic validity as does the diagnosis, meningococcus meningitis.

Virus isolations effected in Minnesota from 1955 to 1957 are listed in Table II. As is apparent from Table II the agent responsible for the viral central nervous system disease that occurred in Minnesota in 1955 was the poliovirus. In 1956, while poliovirus was still operative, Coxsackie B5 virus was isolated from cases of central nervous system disease more frequently than was any type of poliovirus. In 1957 the predominant virus by far was another and for Minnesota, a new one, ECHO 9 virus. It is reasonable to suppose that the Coxsackie B5 virus was not present in Minnesota, at least in readily detectable amount, in 1955 because the isolation techniques used in 1956 were the same as those used in 1955 and the virus would have been picked up had it been there. The

TABLE II. VIRUS ISOLATIONS IN MINNESOTA 1955-1957* (PATIENTS)

	1955	1956	1957

St. Louis encephalitis		3	
Lymphocytic choriomeningitis	5	11	2
Aseptic meningitis, cause undetermined†	47	78	421

*Data provisional.

†Includes encephalitis and meningo-encephalitis of unknown etiology.

ECHO 9 virus can be detected in monkey kidney tissue cell culture but not in the HeLa cell cultures routinely used in Minnesota for poliovirus and Coxsackie virus isolation. Though this virus may have been present to some extent in Minnesota in 1955 and 1956, there is good epidemiologic evidence to believe that it made its first clinical appearance in 1957.

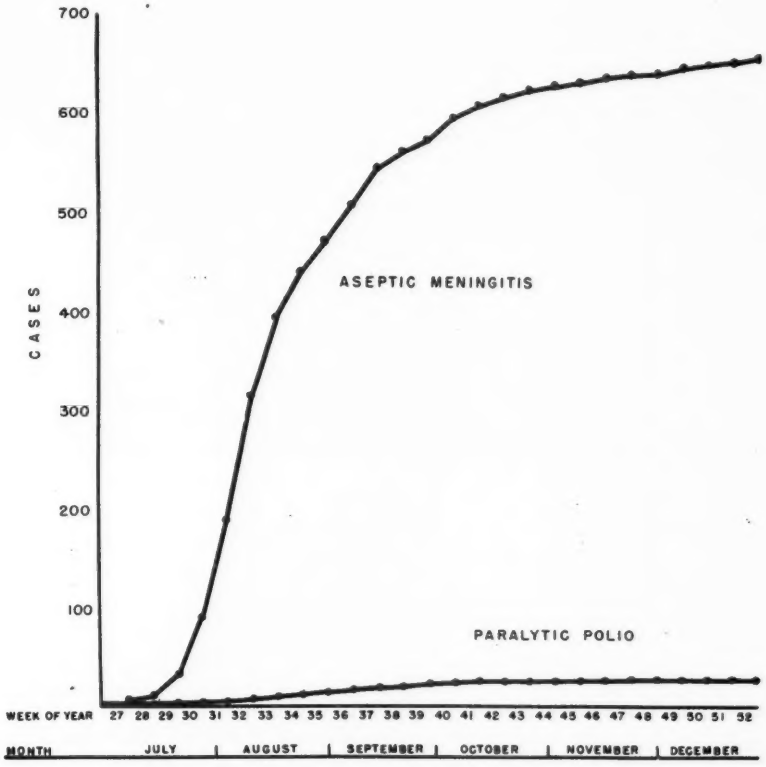

Fig. 1. Cumulative incidence, aseptic meningitis and paralytic polio, Minnesota, 1957.

A more comprehensive view of Minnesota's experience with viral central nervous system disease is presented in Table III. This table lists the diseases by name and includes more than those cases which were characterized by the isolation of the etiologic agent. These additional cases were admitted to the different diagnostic categories on various grounds. In some instances the evidence for admission was serologic; in others it was epidemiologic; and some cases were classified solely on clinical grounds if these were reasonably sound. This last group naturally includes cases that were subjected to the exclusion process for final diagnosis. But no case was finally classified until all the laboratory and historic data were available for a critical appraisal. In many instances, the ultimate decision was not made until after consultation with the original attending physician in order to secure the benefit both of his retrospective thinking and any additional observations he might have made subsequent to the period of the acute illness. The table does not include postinfectious encephalitis such as occurs after measles, rubella, chickenpox, et cetera.

It is possible from the data of Table III to appreciate the extent and the nature of the viral central nervous system disease problem as it existed in Minnesota from 1955 to 1957. It is obvious that the arthropod-borne encephalitides pose no problem. The few cases listed were diagnosed on the basis of serologic results. It is interesting to note that two of the patients having St. Louis encephalitis most probably acquired their infections while on visits to Nebraska. These cases must be

considered entirely sporadic in nature. None of them was characterized by profound disturbances of consciousness although lethargy was mentioned as a symptom. Lymphocytic choriomeningitis occurred with more frequency but was still of minor incidence. These cases, too, were admitted on the basis of serologic evidence but in one instance the virus was isolated from the cerebrospinal fluid. Mumps meningo-encephalitis occurred with regularity throughout the three years. This is a well-defined entity which yields almost invariably good serologic responses which in themselves are diagnostic. Parotitis is not always present; in fact, it is absent in somewhat less than half the cases.

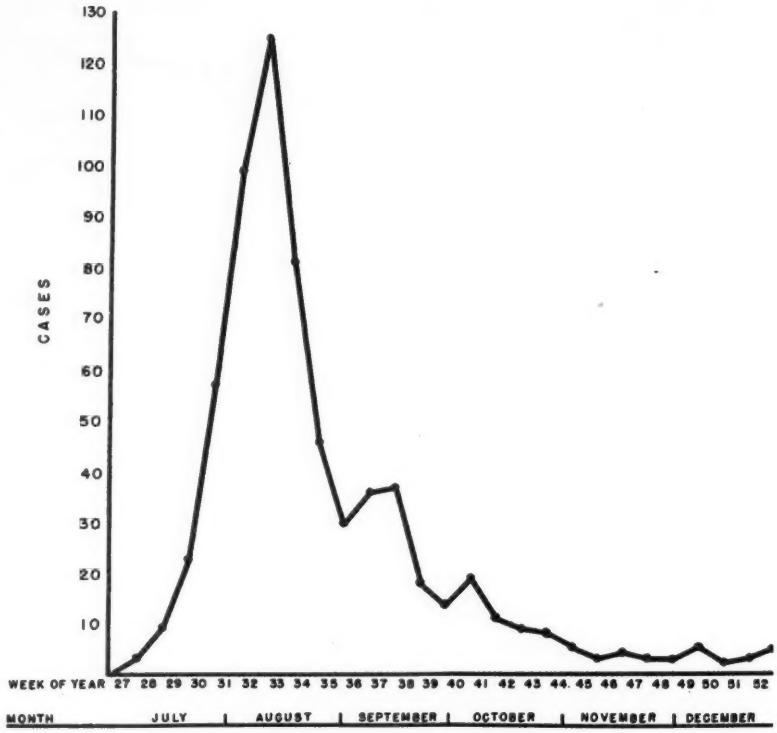

Fig. 2. Epidemic curve, aseptic meningitis, Minnesota, 1957.

The conditions, then, which remain as the bulk of the experience in aseptic meningitis are poliomyelitis, Coxsackie B5 aseptic meningitis, ECHO 9 aseptic meningitis, and aseptic meningitis of undetermined cause.

Quite definitely 1955 was a poliomyelitis year even though the total incidence was low. Poliomyelitis in 1956 was of still lower incidence but in this year there was a definite outbreak of aseptic meningitis due to Coxsackie B5 virus.[3] Considering that thirty-two of the finally accepted cases of Coxsackie B5 infection were initially reported as nonparalytic poliomyelitis, it can be said that during 1956 the reporting of nonparalytic poliomyelitis was attended by an error of 29 per cent. This, of course, in no way reflects on the diagnostic acumen of the attending physician. If the Coxsackie B5 outbreak was considered striking, the epidemic of ECHO 9 aseptic meningitis in 1957 was truly dramatic.[4]

While both of these events, the Coxsackie B5 and the ECHO 9 occurrences, were in time settled on a sound virologic basis, the presence of something unusual was preliminarily suspected on purely epidemiologic grounds. In August of 1956 a cluster of reports of nonparalytic poliomyelitis was noted to be accumulating in certain areas of the state without mention of paralytic disease originating from the same areas. These areas were almost exclusively confined to a few counties in the south-central region of the state. Along with this, the laboratory was reporting the isolation of

cytopathogenic agents, not poliovirus, from the cases in these same areas. It was thus an epidemiologic probability and a laboratory certainty that something besides poliomyelitis was occurring.

meningitis, suspected nonparalytic poliomyelitis, viral meningo-encephalitis, and others. What happened to this group as laboratory evidence accumulated is shown in the last column of Table

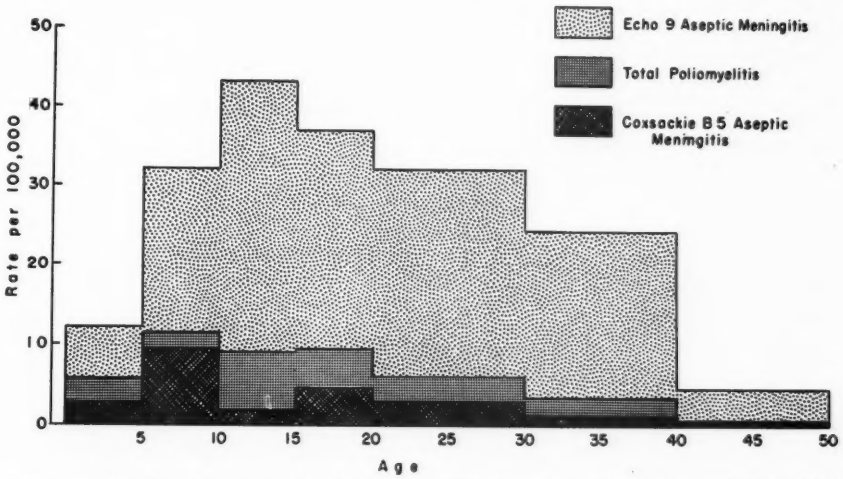

Fig. 3. Age distribution, total poliomyelitis, 1956, Coxsackie B5 aseptic meningitis, 1956, and ECHO 9 aseptic meningitis, 1957, Minnesota.

The ECHO 9 occurrence was suspected even earlier. By the end of July in 1957 the disproportion between nonparalytic and paralytic disease of the central nervous system was so great as to constitute *prima facie* evidence that the nonparalyzing aseptic meningitis was not poliomyelitis. In addition, the appearance of a rash in a certain percentage of the cases made it quite certain that a new disease entity was attacking the population—a disease entity that was not poliomyelitis and not Coxsackie B5 aseptic meningitis (Fig. 1).

The raw data behind the title line "aseptic meningitis, etiology undetermined" in Table III yield the evidence for an interesting reporting phenomenon referred to earlier. In 1955, the forty-seven cases finally comprising this category were originally reported as fifteen cases of suspected poliomyelitis, thirty cases of nonparalytic poliomyelitis, one case of Western equine encephalitis and only one case of aseptic meningitis as such. It was easy to rule out poliomytlitis and encephalitis in these cases as the sera from these patients contained no antibodies against the diseases mentioned in the original reports. In 1957, apparently bearing the Coxsackie B5 experience of 1956 in mind, physicians reported a total of 658 cases under various designations such as aseptic III (paralytic poliomyelitis excepted). As more laboratory evidence becomes available the total of the remaining cases still carried as "aseptic meningitis, cause undetermined" will be whittled down still further and assigned to other and more definite categories. Undoubtedly most of them will be classified as ECHO 9 infections. The increased reluctance of physicians to make the diagnosis of nonparalytic poliomyelitis is thus readily apparent. This reluctance is also evident in considering the proportion of poliomyelitis cases reported as nonparalytic in the three years from 1955 to 1957. In 1955, 68 per cent of the accepted cases of poliomyelitis were listed as nonparalytic; in 1956 the proportion was 55 per cent; in 1957 there were equal proportions of paralytic and nonparalytic poliomyelitis reported.

The diagnostic dilemma of the practicing physician can be profound and troublesome. The season of occurrence is of no diagnostic help to him except for mumps meningo-encephalitis. This condition does tend to occur more frequently in the spring of the year well in advance of the usual poliomyelitis season. Also the presence of parotitis and/or orchitis may make the diagnosis self-evident. But nonparalytic poliomyelitis, Coxsackie B5 aseptic meningitis and ECHO 9 disease all oc-

TABLE IV. ATTACK RATES BY AGE PER 100,000 FOR NONPARALYTIC POLIOMYELITIS, 1956; COXSACKIE B5 ASEPTIC MENINGITIS, 1956; AND ECHO 9 ASEPTIC MENINGITIS, 1957
Minnesota (based on reports)

30-39	2.5	1.1	24.5
40 and over	.3	.3	4.5

cur during the same time of the year. In Minnesota, in 1955, poliomyelitis peaked during the first half of August. In 1956 both poliomyelitis and Coxsackie B5 meningitis peaked during the second half of August. The ECHO 9 aseptic meningitis of 1957 showed its peak during the second week of August (Fig. 2).

The age distribution of these three conditions is interesting, and is shown in Table IV and Figure 3. The age distribution curve for nonparalytic poliomyelitis and Coxsackie B5 are similar in that they show the highest incidence in the earlier years of life. This is characteristic of a population where childhood experience with a disease results in relative immunity for the more adult sections of that population. The situation with respect to ECHO 9 aseptic meningitis is different. Here the attack rates for ages five to forty are similar enough in magnitude to give to the curve of distribution a definite segment of plateau-like flatness. The lower rates under five and over forty might very well be due to differences in exposure potential. This strongly suggests that adults in Minnesota had had no previous immunizing experience with ECHO 9 virus and that consequently this infection was new to the state.

Geographically, in Minnesota poliomyelitis has tended to occur in more or less well-defined clusters. In 1955, for example, it was possible to map out six restricted areas where there were concentrations of cases. In 1956, with a lower incidence of poliomyelitis, it was still possible to demonstrate localization into three spots. The Coxsackie B5 outbreak was also well localized in that it occurred principally in the south-central counties of Minnesota and here principally in two counties. This is not difficult to understand if one considers the Minnesota experience merely a northward extension of what had been happening to a greater extent in Iowa. The geographical separation of the poliovirus and Coxsackie B5 virus that year was sharp. Poliovirus was not recovered from cases in those areas where Coxsackie B5 virus was being found and conversely where there was Coxsackie B5 virus, there was no poliovirus (Fig. 4).* The epidemic of ECHO 9 aceptic meningitis of 1957 was most intensively studied in the Twin Cities area but there is good reason to believe that this infection was widespread throughout the state. The poliomyelitis experience in Minnesota for 1957 was quite small and the cases appear to be confined to the areas of greatest population density.

Clinically, aseptic meningitis due to Coxsackie B5 virus and nonparalytic poliomyelitis cannot be told apart. The signs, symptoms and cerebral spinal fluid findings cannot serve to distinguish between the two.[3] ECHO 9 aseptic meningitis, however, does have several very suggestive clinical characteristics. Foremost is the exanthem which may occur in approximately 30 per cent of the cases. This rash has been described a number of times elsewhere.[4,5] It is sufficient to say here that it is maculopapular in nature, it is often transient and it resembles rubella but without any characteristic lymphadenopathy. The headache in ECHO 9 aseptic meningitis is often exceptionally severe. In the Minnesota series the headache was described as severe in 42 per cent of the cases. The headache was so characterized spontaneously, without the leading question being asked. One pediatrician reported the unusual fact that patients as young as three years of age had complained of headache. A woman patient averred that she would much rather endure an episode of migraine, to which she was subject, than the headache associated with this disease. Indeed, physicians often stated that they had had to resort to prescribing Demerol or morphine for relief of the pain. In the cerebrospinal fluid, the number of cells per cubic millimeter is more often over 300 and definitely more often over 1000 as compared to the cell counts in poliomyelitis and Coxsackie B5 aseptic meningitis.[4]

An important aspect of the study of this epidemic consisted of visits to the families of the reported index cases in Hennepin and Ramsey counties. These families were queried as to the existence of concurrent and similar illness among the various household members. The results of these visits, although not yet completely analyzed, support the observation that multiple cases of illness did occur within single households. The data also

*See page 75.

indicate that the disease spectrum was wide. In many cases of concurrent illness, the symptom constellations did not include stiff neck or stiff back. A rash was described as occurring with a mild set of symptoms as well as with a severe set which included all the signs of meningeal irritation. Finally, in some cases the whole disease was represented only by a fever and rash.

In Minneapolis, for example, of 416 household exposures to an index case, there were 168 instances of illness occurring within thirty days before or after the onset of the illness in the index case. Of these 168 patients, eighty-two were males and eighty-six females; 104 had either headache, stiff neck, or stiff back; eighty-three were reported to have had fever; sixty had nausea, vomiting, diarrhea, and abdominal pain; thirty-five had sore throat; and twenty-seven had a rash. The secondary attack rate thus comes out to at least 25 per cent and at most 40 per cent—a remarkably high secondary attack rate.

These calculated secondary attack rates as well as the empirical observation of the widespread nature of this disease quite naturally inspired a number of questions: *Just how extensive was this outbreak? How many people did it really involve?* An attempt was made to answer these questions by designing a statistical survey to sample populations in Ramsey and Hennepin counties. Practical difficulties presented its extension to other parts of the state. While the results obtained are not strictly applicable to the whole state, they do permit a reasonable overall approximation.

The results of this survey are shown in Table V and represent the best estimate we have at present of the actual incidence of ECHO 9 disease, as it occurred in Hennepin and Ramsey counties from July 1, 1957 to September 20, 1957. Table V also compares the proportions of estimated cases in various localities to the proportions of reported cases in these same localities. As can be seen, except for one area, the concordance is very good. These agreements support the view that the estimates are the reasonable result of a valid method. In fact, physicians to whom these results were reported preliminarily showed no surprise at the magnitude of the estimates. Their own experience as well as the experience of their colleagues did not lead them to believe that the figures were disproportionate in any direction.

TABLE V. ESTIMATED AND REPORTED INCIDENCE OF ASEPTIC MENINGITIS (ECHO 9)
Minnesota, 1957, Hennepin and Ramsey Counties

	Estimated Population	Estimated Cases	Per Cent of Estimated Total	Reported Cases	Per Cent of Reported Total
Hennepin County					
Minneapolis	552,000	91,061	41.3	127	43.0
Bloomington	35,000	17,888	8.1	22	7.5
Richfield	37,000	15,857	7.2	15	5.1
St. Louis Park	39,200	9,800	4.4	5	1.7
Other county areas	133,510	23,423	10.6	56	19.0
Total	796,710	158,029	71.6	225	76.3
Ramsey County					
St. Paul	336,000	45,073	20.4	60	20.3
Roseville	29,800	10,927	5.0	3	1.0
Other county areas	77,811	6,642	3.0	7	2.4
Total	443,611	62,642	28.4	70	23.7
Total	1,240,321	220,671	100	295	100

The cases reported in Hennepin and Ramsey counties represented 52 per cent of the total reports. Using this as a factor and projecting the two-county estimate to the state as a whole, it would appear that the total state incidence was 424,367 cases. Such a projected estimate, however, is not as secure as is the two-county estimate because the attack rates in other areas of the state, especially in truly rural areas, may have differed from the attack rates in the metropolitan area.[4]

Minnesota was able to study these outbreaks in a more or less complete manner because of the existence of its poliomyelitis surveillance unit. The methods developed by this unit were immediately adaptable to the study of other aseptic meningitides whenever they occurred. The poliomyelitis surveillance unit of the Minnesota Department of Health was established in 1955 for the express purpose of watching with considerable epidemiologic and laboratory detail, the course of

poliomyelitis as it might be influenced by the Salk vaccine which came into first use in Minnesota during 1955. This basic purpose was followed in 1956 and in 1957. But the inevitable march of events forced this unit into excursions into the field of aseptic meningitis due to viruses other than the poliovirus. In fact, it was surveillance routine that enabled the early appreciation of the existence of these problems. Had it not been so, the studies on Coxsackie B5 and ECHO 9 aseptic meningitis would have been retrospective, a distinct disadvantage.

The dynamism in the enterovirus field will require physicians, laboratory workers, and public health workers to reorient themselves and be prepared to work toward a further reduction in the size of the "cause undetermined" category of virus diseases particularly in that class known as aseptic meningitis. More emphasis will have to be placed on the need for establishing an etiologic diagnosis in individual cases. Perhaps the most important guidepost for the physician is the pattern of central nervous system disease which is occurring in his community. Should it be noted that there is a series of such cases occurring in a community with none of them, or a disproportionately small number of them, showing any lower motor neuron paralysis, then it is proper to infer that the disease which is occurring with major frequency is not poliomyelitis. This is the time to bend every effort towards establishing a definite etiology. From the laboratory standpoint the isolation of the offending agent in the great majority of instances can be made from the stool. Such specimens should be collected as early as possible in the course of the disease as the chances for successful isolation depreciate after the first ten to fourteen days. In addition to this, paired blood samples should be submitted; the first of these drawn preferably within the first five days of onset and the second drawn during the convalescent period about two weeks later.

It will be desirable to try and establish the presence, if any, of any long term effects of such diseases. This can be determined with greatest accuracy by long term follow-up of patients who are known to have had the disease currently or in the recent past. As time goes by the information from retrospective studies becomes more vague, more difficult to interpret and finally quite useless. Sabin has pointed out, on the basis of serological studies, that women of childbearing age are particularly vulnerable to ECHO 9 infection should it be present in any community.[5] *Are pregnant women more susceptible really as they seem to be in the case of poliomyelitis and if infected will there be any effect on the fetus?* The similarity of the ECHO 9 rash and the rash of rubella increases the provocativeness of this conjecture. Another question relates to the relative antiquity of these infections. As we merely becoming newly acquainted with old neighbors?

Finally, from the administrative standpoint, it has been suggested that in the future poliomyelitis be reported as such only when the disease is paralytic and that all nonparalytic conditions be reported under some general term such as aseptic meningitis. At a later date, then, the aseptic meningitis report could be qualified by designating the etiology, if it can be determined. This scheme certainly seems reasonable under present circumstances and would have the merit of bringing to the attention of health departments and epidemiologists cases which might remain unknown because the present regulations do not require a report. This procedure, too, fits in with the present diagnostic temper of physicians.

These are complex questions and the quickest results will be obtained by promoting a closer working relationship between the practicing physician and the public health departments.

The Response to the Controlled Infection by Attenuated Poliomyelitis Virus

In the Neonatal Period and Early Infancy

● *Adequate titers of poliomyelitis antibodies can be obtained in women, during pregnancy, by injecting them intradermally with an amount of Salk vaccine five times smaller than the usual subcutaneous dose. The infant eliminates, in about five weeks, half of the antibodies received at birth. Placentally transferred passive immunity to poliomyelitis can be converted to active lasting immunity by the oral administration of live attenuated poliovirus vaccine to newborn infants before leaving the hospital nursery.*

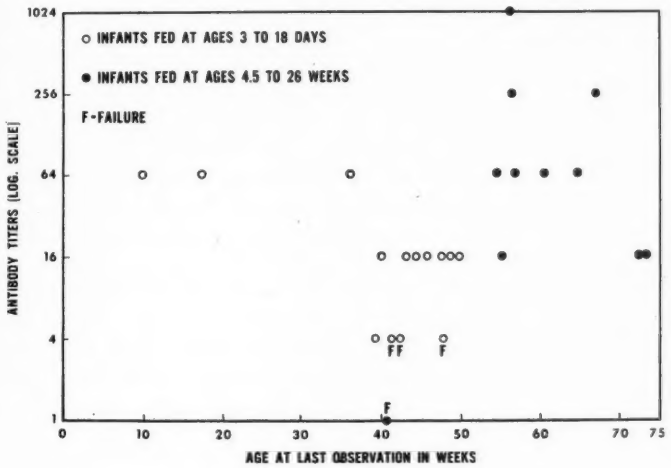

Fig. 2. Antibody response on twenty-five infants fed attenuated Type I poliomyelitis virus (SM strain), Minneapolis, 1957.

MAURICIO MARTINS DA SILVA, M.D., M.P.H.
Washington, D. C.

THE capacity of the newly-born infant of man and animals to acquire congenital passive immunity against viruses following injection of the mother during pregnancy with the corresponding antigen, has been satisfactorily demonstrated and reviewed by Anderson et al.[1] Pinto, in 1949,[2] found the progeny of cotton rats highly resistant to challenge inoculation if their mothers were injected during pregnancy with the adapted Lansing strain of poliomyelitis virus. Similarly, Curley and Gordon[3] have proven in mice the transmission of passive protection against the M.M. strain of mouse encephalomyelitis virus from immune mothers to offspring. These authors demonstrated further that challenging the passively protected young mice with fully virulent virus resulted in active lasting immunity which developed during the declining phase of placentally transmitted antibodies.

Poliomyelitis antibodies were first shown to be passively transferred in the human from mother to baby by Aycock and Kramer in 1930.[4] It has

Presented at the annual meeting of the Minnesota State Medical Association, Minneapolis, May 23, 1958.

been suggested that this placentally transferred passive immunity can be converted to an actively acquired immunity by the occurrence of subclinical infections during the phase of declining protection of maternal antibodies. This mechanism would partially explain the relative absence of poliomyelitis epidemics in most tropical and subtropical countries,[5] an observation however which seems no longer substantiated as socio-economic and hygienic conditions improve in these areas.

TABLE I. GEOMETRIC AVERAGE OF FOLD INCREASE IN ANTIBODY TITERS AFTER TWO INJECTIONS OF SALK VACCINE

	Method of Vaccination					
	Subcutaneous			Intradermal		
	Type I	Type II	Type III	Type I	Type II	Type III
Lot 028849-A	11.2 (24)	9.1 (25)	9.8 (25)	9.1 (25)	13.5 (25)	12.3 (22)
Lot 029126-A	10.7 (20)	20.9 (20)	14.8 (20)	17.4 (16)	18.6 (19)	19.1 (17)
Lot 9184-653802	8.3 (19)	8.4 (23)	10.4 (19)	12.0 (15)	17.0 (21)	24.0 (17)

Those with non-measurable antibody titers excluded—number of observations in each average recorded in parenthesis.

The results being presented here are limited to: (a) a comparison of the antibody response in pregnant women to Salk vaccine administered by subcutaneous and intradermal injection, (b) the measurement of passive transfer of naturally occurring and Salk-vaccine-induced poliomyelitis antibodies from mother to infant and of persistence of these maternal antibodies in the infant, (c) the response of newborn babies and infants under six months of age to infection with the attenuated Type 1 poliomyelitis virus (SM strain).

One hundred and thirty eight pregnant women were selected for vaccination with Salk vaccine. Half of this group received the vaccine intradermally (0.2 ml. twice, three to four weeks apart), the other half subcutaneously (1.0 ml. twice, three to four weeks apart). Three lots of commercially-prepared Salk vaccine from two different manufacturers were used.

Blood samples were collected immediately before the first injection and approximately four weeks after the second. At delivery a third specimen of maternal blood and a sample of cord blood were drawn. Blood samples were collected from the infants at approximately three-month intervals for one year or until no detectable antibody titers remained. Quantitative assay for neutralizing poliomyelitis antibodies in the sera was performed using HeLa cell cultures. Six serial four-fold dilutions of the serum (1:4 to 1:4096) were prepared and four tubes of HeLa cell culture per dilution were used. The end point of titration was determined by microscopic observation of the inhibition of the cytopathogenic effect of the virus.[6]

TABLE II. ANTIBODY RESPONSE AND STOOL ISOLATION RESULTS ON 25 INFANTS FED ATTENUATED TYPE 1 POLIOVIRUS (SM STRAIN) Minneapolis, 1957

Ages at Feeding	Number of Infants	Amount Fed $T.C.D._{50}$	Per Cent With Positive Stools	With Antibody Response at Last Observation		Median Weeks of Observation
				Number	Per Cent	
3-18 days average 8.7	14	4.2-5.0	60.4	11	78.5	43
4.5-26 weeks average 11.9	11	4.2	90.9	10	90.9	49
Total	25	4.2-5.0	76	21	84.7	

To a group of twenty-five infants under the age of six months, born of mothers vaccinated during pregnancy with Salk vaccine, Type I attenuated poliovirus (SM strain) was given orally mixed in nursery formula or regular cow's milk. The presence of virus in the stools and the immune response in each child was followed by serial stool cultures at weekly intervals for five to twelve weeks and by serum antibody determinations at one-month to three-month intervals up to approximately one year.[7]

TABLE III. SERUM ANTIBODY TITERS AT LAST OBSERVATION FOLLOWING PARALYTIC POLIOMYELITIS (VIRUS TYPES 1 AND 3) AND AFTER IMMUNIZATION WITH ATTENUATED TYPE 1 POLIOVIRUS (SM STRAIN) Minneapolis, 1957

Group	Number of Subjects	Time of Last Observation in Weeks (Median)	Serum Titer (Median)
Adult patients with paralytic poliomyelitis	7	51	1:64
Infants fed SM strain at ages 3 to 18 days	11	43	1:16
Infants fed SM strain at ages 4.5 to 26 weeks	10	49	1:64

Results

Intradermal inoculation elicited as good an antibody response as the larger subcutaneous dose in those subjects whose antibody titers were measurable before and after vaccination (Table I). The lots of Salk vaccine used varied in antigenic potency.

Cord blood antibody titers were equal to or within one tube difference (within the error of the method) of maternal titer at delivery in over 85 per cent of the instances where such comparisons could be made.

The "half life" of Types 1, 2, and 3 antibodies present in the neonatal period was approximately five weeks (thirty-seven days) regardless of the level of the cord blood titers. Detectable antibody titers were present at nine months of age in the majority of infants who had an antibody level of 1:1024 or greater at birth. The gradual decline of antibody titers of two infants in our study during the first year of life is depicted in Figure 1.

No significant untoward reactions were observed in the infants fed the attenuated virus. The slight gastrointestinal symptoms occasionally reported were probably no more numerous than they would be during a comparable period with unvaccinated infants, particularly since mothers were warned to be especially observant.

Wiener[8] and Good[9] have reported that normal newborn infants up to approximately three weeks of age are immunologically inert and incapable of producing gamma globulin or responding to a variety of antigenic stimuli with measurable amounts of antibodies. In Table II results of the antibody response and virus isolation in the stools of fourteen infants under three weeks of age (age range three to eighteen days) are compared with similar data from eleven older infants (age range four and five-tenths to twenty-six weeks of age). It appears that a higher percentage of intestinal infections was induced in the older group with smaller doses of virus. Two infants under two weeks of age with titers no higher than expected from passive antibodies were counted as failures. However, they presented evidence of infection (prolongued virus multiplication in the intestine, spread of virus to siblings) and may eventually be considered successfully vaccinated when later blood samples are obtained. Table III summarizes the serum antibody titers of both groups of infants at the time of the last observation (forty-three and forty-nine weeks after feeding) and compares them with the titers of seven adult patients with severe paralytic poliomyelitis about fifty-one weeks from the acute disease. It can be seen that the median titer of the older infants is equal to the titer of the paralytic polio patients at approximately one year after vaccination and acute illness, respectively. Figure 2* shows the distribution of titers, when last observed, of the two groups of infants. The expected titers of passive anti-

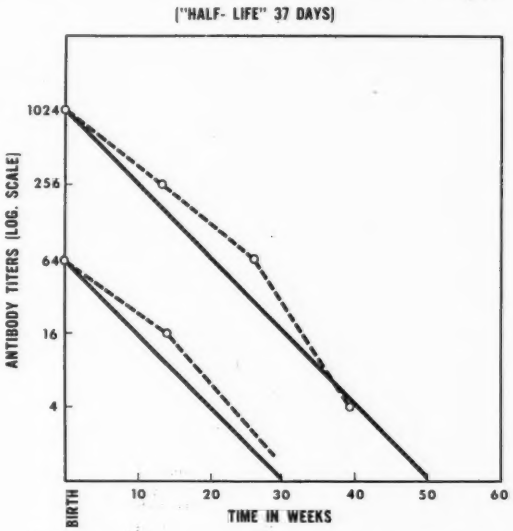

Fig. 1. Rate of decrease of passive poliomyelitis antibody titers in infants ("half-life" thirty-seven days).

bodies of the older group (represented by dark dots), at the time of observation, is below one in all instances and, therefore, the titers obtained represent "active" antibodies and presumably are the result of vaccination. The observed titers in eleven of the younger infants are above expected levels of passive antibody and thus must represent "active" response to the vaccine. However, final titers will have to await later observations.

Figures 3, 4, 5 and 6 exemplify the antibody response of four infants aged six to seven days, after being fed $10^{4.2}$ to $10^{5.0}$ T.C.D.$_{50}$ of Type 1 virus and observed for ten to twelve months. The dotted lines represent the expected exponential drop in passive antibody titer in these infants ("half-life" five weeks). The antibody response of the younger infants seems to level off at a titer of 1:16.

Conclusion

In an immunization program against poliomyelitis with the live poliovirus vaccine it would appear desirable to start vaccination as early in life as possible. If infection with the attenuated poliovirus and the resulting active immunity could be induced during the declining phase of passive anti-

*See page 83.

bodies, uninterrupted protection against the disease would be offered from the moment of birth. The newborn period would logically offer the best opportunity for such a vaccination program since poliomyelitis antibodies are transferred to the baby at the time of delivery. We have observed that the proportion of pregnant women with naturally occurring poliomyelitis antibody titers equal to or

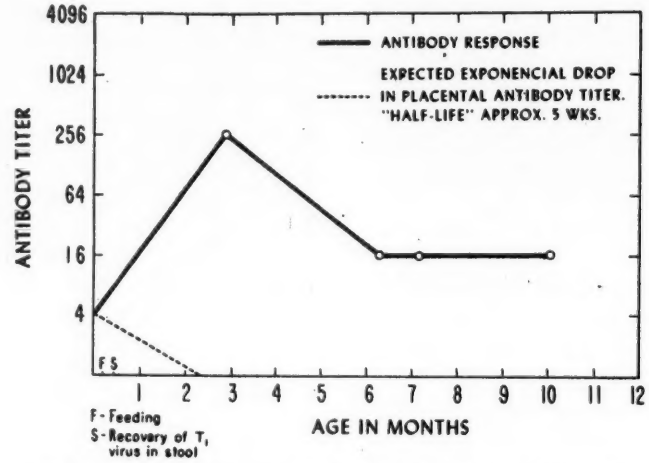

Fig. 3. Antibody response of Baby D.S. after being fed $10^{5.0}$ T.C.D.$_{50}$ of Type I virus (SM strain) on sixth day of life.

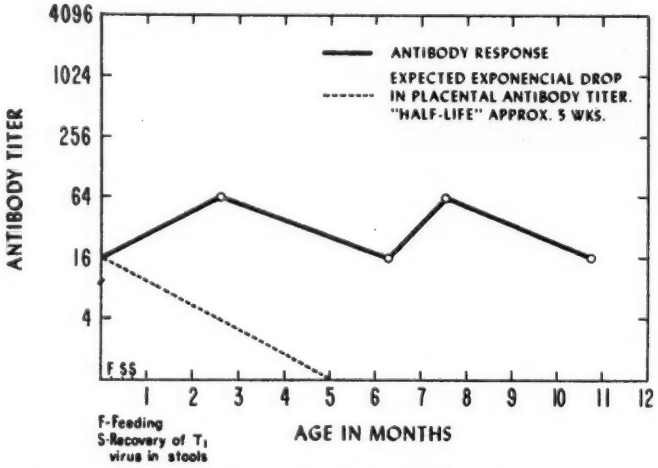

Fig. 4. Antibody response of Baby S.R. after being fed $10^{5.0}$ T.C.D.$_{50}$ of Type I virus (SM strain) on seventh day of life.

it is the first time the baby comes under medical supervision and since almost all births in this country occur in hospitals.

From the observations presented here, it seems that vaccination with the live poliovirus vaccine is possible and adequate in the newborn period although titers obtained are lower than those attained at a later age. With the generalized use of Salk vaccine in pregnant women, high titers of greater than 1:1024 was increased from 10 per cent to about 44 per cent after two injections of Salk vaccine before delivery.[6] The only baby in our series with an extremely high serum titer at birth (1:4096 or higher) failed to respond to the oral vaccine given on the fourth day of life.

Whether or not a larger dose of virus would overcome the difficulty is at present being investigated.

Some International Aspects of Virus Diseases

FRED L. SOPER, M.D.
Washington, D. C.

Dr. Soper is Director of the Pan American Sanitary Bureau, World Health Organization, Washington, D. C.

AMONG the pestilential diseases which inspire dread wherever they occur, the two virus diseases—smallpox and yellow fever—hold high rank. These diseases long have been recognized as serious international problems and international sanitary regulations prescribe the measures to be taken both by infected and receptive countries for the protection of uninfected areas. The current regulations* largely reflect the traditional practice of a previous generation, whose equally important objectives were (a) to prevent the movement of communicable disease from place to place by ship, and (b) to avoid all delays of shipping by quarantine or other restrictive measures. These regulations specifically preclude the application of any measures by health authorities to passengers to prevent the introduction of virus disease other than smallpox and yellow fever.

Yellow fever has not invaded the United States since 1905, yet the federal health authorities have followed with unusual interest the reported movement of yellow fever virus through the forested areas of Panama and four of the five Republics of Central America during the last decade and have been disturbed by rumors of the disease in Mexico in 1957 and 1958. This interest and preoccupation are natural and justified since the last time yellow fever is known to have been in Mexico (1924) a patient with yellow fever died in a hospital in Houston, Texas, having arrived in the United States by boat and passed quarantine at New Orleans. The federal authorities are in a difficult position since they have the responsibility for protecting the United States against the introduction of yellow fever, but do not have the authority to carry out the only measure which would give complete protection against the introduction of yellow fever virus, namely, the eradication of the *Aëdes aegypti* mosquito from our ports and cities.

In 1947, the representatives of the twenty-one American Republics, meeting as the Directing Council of the Pan American Sanitary Organization, recognizing the impossibility of protecting the cities and towns of the Americas from invasions of yellow fever virus from the animal reservoirs in the forests, through traditional notification and vaccination procedures, approved a program for the eradication of the only urban vector, the *Aëdes aegypti* mosquito, from the Hemisphere. To be successful, this effort had to be universal throughout the infested areas. Fortunately, the areas under the control of France, the Netherlands and the United Kingdom have entered wholeheartedly in this hemispheral project. This effort is an important landmark in public health practice; for the first time in history, the nations of a region banded together for the complete solution of a common problem through corrective measures to be taken in each country.

In not protecting itself against the possible introduction of yellow fever virus and in not collaborating with the other nations of the Americas in the permanent solution of this common problem, the United States is shamefully behind the progress registered throughout most of the hemisphere. So long as the United States harbors the *aegypti* mosquito, it will be a potential source of reinfestation of those of our neighbors to the south, who have it no more. The 1958 analysis shows that the continental campaign for the eradication of the urban vector of yellow fever, officially approved in Buenos Aires in 1947, is well advanced; *Aëdes aegypti* is no longer to be found in Bolivia, Brazil, British Honduras, the Canal Zone, Ecuador, French Guiana, Guatemala, Nicaragua, Panama, Paraguay, Peru, Uruguay; the eradication effort is almost complete in Chile, Colombia, Costa Rica, Honduras, and El Salvador; and Ar-

Presented at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, May 23, 1958.

*International Sanitary Regulations of the World Health Organization (1951).

gentina, Venezuela, Cuba, the Dominican Republic and Haiti have organized national *aegypti* eradication programs. Only the United States and one other republic are absent from these lists. This republic insists it cannot undertake the eradication of *aegypti* until the United States does so, since, given its geographical position, reinfestation would be continuous from the United States.

Although the federal service does not have the authority to eradicate *aegypti* in the cities and ports of this country, it is clear that the individual state, eradicating *aegypti* independently of concomitant action taken by other states, would be subject to reinfestation from neighboring states. The initiative in planning and co-ordinating the eradication of *aegypti* in the United States (to comply with our moral obligation to the other countries of the continent) must be taken by the United States Public Health Service. The rumor that the United States—which spent so many millions to fight foot and mouth disease in Mexico—has hesitated in the case of *aegypti* eradication here, because of the cost of the operation, has caused much merriment among health workers of other countries. They have even suggested among themselves that those countries which have already made the investment necessary to eradicate *aegypti* should contribute to a fund for its eradication in the United States, as a means of protecting their own investment.

So long as quarantine and international sanitary regulations have existed, just so long has it been obvious that the attempt to prevent the movement of smallpox from country to country through mutual notification of outbreaks, compulsory vaccination of international passengers, and quarantine of uncertified passengers, can be only partially successful.

In 1936 a severe outbreak of smallpox was initiated in Uganda by a certified, but unvaccinated ten-months-old child from Bombay, India; and in 1947, a bus passenger from the Mexican border introduced smallpox into New York City in spite of the border quarantine services. In the following years, Mexico has carried out an intensive vaccination campaign and since 1951 has not reported cases anywhere in the Republic. Clearing Mexico as a seedbed of infection has undoubtedly been a primary factor in the absence of reported smallpox in North and Central America and the West Indies since 1954. It has long been obvious that freedom from the threat of smallpox must depend either upon maintaining a high level of immunity in the population through vaccination and revaccination or upon eradicating smallpox from other countries. Experience has shown that it is difficult to maintain a satisfactory degree of immunization, as witness the near panic and the emergency vaccination of many millions of persons in the metropolitan area of New York in 1947.

Since 1950 the countries of the Americas are committed to a program of smallpox eradication. The Pan American Sanitary Organization is co-ordinating the activities in various countries and has been particularly active in developing effective vaccines, of both the classical and desiccated types, for use under varying conditions. This eradication effort in the Americas has been a low-pressure effort, designed not only to eradicate smallpox, but also to make provision for continuing production of vaccine and routine immunization of a certain part of the total population each year. It has been recognized, in effect, that the Americas could not get the full benefit of eradication on a regional basis, so long as the threat of reinfection from other parts of the world persisted.

The Eleventh World Health Assembly, meeting here next week, will consider a draft resolution presented by the USSR, calling for a high-pressure campaign for the world-wide eradication of smallpox by 1962!* Now that the USSR has eliminated smallpox in its own population, it realizes that the costly permanent effort needed to maintain that population immune, would be unnecessary, were all of the countries of the world to get rid of smallpox at the same time.

The programs for the eradication of the urban vector of yellow fever and of smallpox in the Americas, and the proposal to eradicate smallpox on a global basis, are part of a new pattern of communicable disease prevention which is evolving as a result of the development of air transportation, the discovery of efficient insecticides, drugs and antibiotics, the rehabilitation of the eradication concept, and the recognition by the nations of the world of the signal value of international health organizations as agencies through which information can be exchanged, research co-

*The USSR proposal was referred to the Secretariat for study previous to reconsideration by the Twelfth World Health Assembly in 1959.

ordinated, and technical and material resources pooled for planning and executing international and even world-wide programs. Smallpox became technically eradicable with the work of Jenner, but only now has it become administratively so.

The protection of the United States from the introduction of disease agents and participation in the International Health Organizations are federal functions, but the United States Government has very wisely had the State Health Services represented on the U. S. Delegations to the World Health Assemblies and has approved state health officials serving as consultants to WHO all over the world. It is then highly fitting that the State of Minnesota and the City of Minneapolis should be co-hosts with the United States Government in holding the Eleventh World Health Assembly here. It is also highly fitting that a number of delegates to the Assembly from other countries should come to this Annual Meeting of the State Medical Association to hear reports on pioneer work done in Minneapolis under the auspices of the State Board of Health, in testing living attenuated poliomyelitis virus vaccine. As Director of the Pan American Sanitary Bureau, I am pleased that the Bureau has had a small part in this work which, important as it may be for the United States, is much more important for those countries without the technical and financial resources to make full use of the inactivated virus vaccine currently available. From the international point of view, it should be noted that, on the basis of the detailed information on tests in Minneapolis, more extensive field tests of the live virus vaccine were begun very recently by the Ministry of Health of Colombia with the participation of the Bureau.

In spite of the recommendation of the Expert Committee of the World Health Organization last year (1957) that large-scale tests of live virus poliomyelitis vaccine should be made, unaccountable opposition to such tests has arisen in some quarters. While countries, which can and are protecting their susceptible population groups with inactivated virus, may be justified in an overcautious approach to live virus vaccine, recognition should be given to the situation in other countries, where conditions remain much the same as before the introduction of the inactivated vaccine. Listening to opponents of testing live polio virus vaccines, one might infer that the introduction of live yellow fever virus vaccine was a criminal procedure at the time it occurred. The introduction of inactivated (formalin treated) yellow fever virus vaccine was followed by uncertain results and in the light of apparent dangerous infections was abandoned by its proponents. Later, when mouse-brain-adapted virus, incapable of producing visceral yellow fever, but highly neurotropic, became available, French workers tested it as a vaccine and eventually vaccinated many millions of persons with it. The workers at the Rockefeller Foundation considered this neurotropic virus dangerous and continued to test various combinations of viruses and immune serum in the laboratory and in the field. These tests continued for several years with less than satisfactory results until nonviscerotropic virus with greatly reduced neurotropism became available late in 1936. This virus, known as 17-D, is the source of all vaccine produced in the Americas and most of that in Europe during the past twenty years.

When Virus 17-D became available to workers in Brazil, tests with it had been limited to a series of monkeys and a small number of persons in New York, yellow fever was active in the State of Minas Gerais and a decision had to be taken as to the propriety of its field use before more extensive laboratory testing. The decision was in favor of its immediate use and, after a cautious beginning, some 40,000 people were vaccinated in 1937 without any untoward incident. The following year, 1938, in the face of a major outbreak of jungle yellow fever, slightly over one million persons were vaccinated, again without incident. In spite of this initial success during two seasons, difficulties were encountered in the following years: first, loss of antigenicity of the substrain of virus used for vaccine production; then, serum hepatitis; and finally, post-vaccination encephalitis. These problems were solved, one by one, and during the past sixteen years no difficulties have been encountered in vaccinating millions of persons with the Virus 17-D vaccine, produced in Brazil. Looking back on the experience with the yellow fever vaccine, it seems unlikely that any of the difficulties met would have been found and eliminated by even a prolonged series of small scale tests.

The WHO Expert Committee's 1957 recommendation of large-scale, live poliomyelitis virus tests is believed to be sound. The field demonstration already begun in a rural county in Colom-

bia, as a follow-up on the Minneapolis tests, should lead without interruption, in the absence of obvious contraindications, to an ever-expanding application throughout this South American Republic. And just as the Minneapolis experience is of value to other countries, so will the Colombian experience be important to Minnesota and to the United States. It would have been difficult to carry out the initial tests in Colombia, and impossible to carry out the large-scale tests projected for Colombia in the U. S. since we have no large populations in areas uninfluenced by the heavy use of inactivated virus vaccine.

Poliomyelitis is, of course, one of the most universal viruses known; it is so widespread that health authorities have despaired of measures to prevent its movement from place to place. The fact that the course of certain especially paralytic outbreaks, which have been studied epidemiologically, can best be explained on the hypothesis of the introduction of a specially neurotropic and rapidly spreading virus at a certain place from which it later spread to other areas, has caused some authorities to consider travel restrictions for at least the more susceptible age groups coming from epidemic areas. Such restrictions were temporarily enforced by various American nations and by at least one country of Europe during the severe outbreak in Argentina in 1956. It is to be hoped that the present studies will result in the development and acceptance of a polio vaccine which will be so cheap and so easy to give that its use can become world-wide for the protection of the 80,000,000 babies born each year into this heavily infected world, before other international complications develop.

Time does not permit mention of the international aspects of influenza and the part international co-operation played in the dramatic experiences of 1957 with the Asian strain. Nor of the importance of rabies, psittacosis, and foot and mouth disease as international problems.

No discussion of the international aspects of virus diseases can ignore the rapidly increasing number and variety of viruses, particularly of the *arbor* and *echo* groups, capable of infecting man, some of widespread, others of very limited distribution, which constitute a whole series of potential international problems. The listing of the names of some of these viruses, generally derived from the place of discovery, is enough to emphasize the international character of these problems; St. Louis, Colorado, California bat, Russian Spring and Summer, Japanese B, Murray Valley, Rift Valley, Belém (Brazil) Ilheos, Mayaro, Sindbis, Semliki Forest, Kyanasur Forest, Bwamba, Bunyamwera, Trinidad, Venezuela EE, Western EE, Eastern EE, Tongaland, Uganda, West Nile, Zika, Chikunguya and Nyaya!

For the uninitiated, it should be stated that *arbor* viruses are not necessarily found in trees but are Arthropod-Borne; and that *echo* viruses are not imitatively repetitious, but are Enteric-Cytopathogenic viruses of Human origin which were at one time thought to be Orphaned, that is lacking any parent disease to which they were related. That this Orphaned condition is not universal for the group is shown by Minnesota's widespread epidemic of *Echo 9* infections in 1957.

As observations continue, conscientious health officers are going to be faced with innumerable questions, to which some answer must be given, such as the following:

What is the potential international threat of the highly fatal hemorrhagic disease, occurring in certain capitals of Asia (Manila and Bangkok), the virus of which has been isolated from *Aëdes aegypti,* the common household mosquito vector of yellow fever? And what is the importance to other countries of Asia and to the forested tropical regions of America and Africa of the Kyanasur Forest Virus of the Russian Spring and Summer Encephalitis group highly fatal to monkeys and to man, transmitted by mites? Should these diseases of Asia be made the object of international sanitary regulations as are *aegypti* transmitted and jungle yellow fevers which they so closely resemble? And are the virus diseases of Asia transmitted by the *aegypti* mosquito of sufficient importance to justify the expense of eradicating this mosquito from that region as is being done in the Americas?

The answers to these and similar questions must await further study and observation, in many different countries; they can not be based on the action of individual countries attempting to protect only their own populations. Regional and global solutions must be sought and in the seeking, the nations of the world can best proceed by using their official health agencies—the Pan American and World Health Organizations—to co-ordinate research, exchange information and co-operate in attacking individual virus problems wherever they may be.

• *Numerous progressive and fascinating studies of psychiatric concepts and methods of therapy have been taking place in the Netherlands. Some undertakings have been on a limited scale, others quite extensive. The program of "out-call" psychiatric consultation as the method of initial evaluation and the monetary rewards for constructive work completed by in-patients are two of the most practical channels of meeting mushrooming needs for psychiatric care. The author's remarks are particularly authoritative because he was trained in the Netherlands and has practiced psychiatry in the United States.*

Some Aspects of Psychiatry in the Netherlands

Their Potential Applications in the United States

CONRAD W. BAARS, M.D.
Rochester, Minnesota

EN ROUTE to Zürich, Switzerland, to attend the second International Congress for Psychiatry, I spent several days visiting various psychiatric hospitals and clinics in the Netherlands. Some of the things I observed there were entirely new to me; others were essentially unchanged from the years I had studied at the University of Amsterdam Medical School. Yet, regarding the latter, much seemed to be different because I evaluated them from a different point of view, that of one grown accustomed to the practice of psychiatry in American state hospitals. The Congress at Zürich brought out some of the differences and many of the similarities between modern American and continental European psychiatry in general (Great Britain's psychiatric practice lies somewhere in between since it possesses features of both). My observations in the Netherlands note the similarities and differences in regard to some particular aspects of psychiatric practice and research.

Some of these observations have been reported in the American literature in recent years,[1,2] although never in sufficient detail to convey their full impact to American psychiatrists. It is the purpose of this paper to give a better understanding of Dutch psychiatry by describing some of its aspects, as follows:

1. The system of domiciliary care or psychiatric first-aid developed by Professor A. Querido and in effect since the mid-thirties.[3,4] If suitably adapted and modified to meet different conditions in the United States, this system may offer a practical solution to the problem of a steadily increasing hospital population.

2. A unique research study for the treatment of mentally disturbed criminals—mostly psychopaths who have not responded to more conventional psychiatric treatment methods. The observations and ultimate results of this group of researchers, headed by Professor Dr. P. A. H. Bann,[5] may be expected to have considerable bearing on the future disposition and handling of delinquent psychopaths in this country.

3. The use of work therapy in mental hospitals, as observed at the mental hospital at Santpoort under its medical superintendent, Dr. W. Ploegsma.[6-8] This hospital serves as an outstanding example of the usefulness of a well-formulated and organized application of the principle of meaningful work and monetary compensation to patient-workers.

4. A novel, if not revolutionary, theory of the origin and treatment of neuroses developed by Dr. A. A. A. Terruwe. This theory provides an acceptable and intellectually satisfying explanation of Freud's basic discovery, the repression. This thought-provoking study with its far-reaching therapeutic implications will be introduced to American psychiatry in the near future when P. J. Kenedy & Sons, New York, publishes the Eng-

lish translations of two books by this author, "Psychopathic Personality and Neurosis" and "The Neurosis in the Light of Rational Phychology." For this reason, as well as for that of space limitation, a discussion of this most important topic will be omitted in this paper.

Domiciliary care, an experiment in mental health.—This system was gradually developed in the city of Amsterdam after the first World War as part of a new program of social reform which included the reorganization and extension of the city's public health department. It is based on the theory that the cure or the rehabilitation of the mentally disturbed person can be accomplished only in society itself, and that a successful stay in society is the only real test of any therapeutic endeavor. This implies that the removal of a mentally ill person from his social background must be considered as an illogical procedure unless indicated for strictly medical reasons.

One of the most important features of this psychiatric first-aid "on-the-spot" service is the opportunity for the psychiatrist to study the conflict in its proper setting. When the psychiatrist and his social worker are called out, they are able to observe and evaluate first-hand the interplay of all factors related to the mental conflict. Without any special effort, the total socio-economic picture, i.e., quality of surroundings, attitude of spouse, parents, siblings or children, the tensions caused by poor living conditions and poverty, lies before them. They can see how the patient is feared, loved, respected or rejected. They see the reactions of the neighbors and the attitude of the patient toward authority. They see signs of hobbies, of interest in social or cultural activity. They get an inkling of the burden of material care that rests on the family.

With all this information readily at hand the expert psychiatrist is able to decide immediately whether rehabilitation of the patient in his own surroundings is feasible, or whether for medical reasons hospital stay is necessary. If the former decision is possible he will find that the attempt to re-establish the disturbed equilibrium is usually of shorter duration, cheaper, more efficient, and more directly concerned with the fundamental conflict, therefore offering more chance of success.

For a better understanding of this unique mental health service which obviously provides social rather than medical treatment in the strict sense of the word, it is helpful to take a closer look at the manner in which the system operates in Amsterdam. This city of approximately 900,000 is rather compactly built, the farthest distance across being not more than six miles. There are twenty-two out-patient treatment centers or "poliklinieken" at which the ambulatory patient can receive specialized therapy provided by his group health insurance program. Each of these twenty-two centers has one psychiatrist among its medical specialists. There are two treatment centers for psychotherapy operating with public grants. The number of psychiatrists in private practice is approximately seventy-five, and the two general hospitals which admit psychiatric patients have together about 300 beds in addition to large out-patient departments.

The mental health service consists usually of twelve psychiatrists, always four or five psychiatrists in training and about twenty-five social workers. Two psychiatrists and two social workers are assigned to each of the six sectors in which the city has been divided. They work on a rotating twenty-four-hour schedule. At night, from the hours of 6:00 p.m. until 8:00 a.m., and on weekends, there is one psychiatrist on duty all the time. There are, on an average, about 3000 adults under supervision, most of whom are living in their own homes and some of them in foster homes. The service receives an average of 250 inquiries daily. Some of these can be dealt with by telephone through quick reference to case records. Others require a home visit by the psychiatrist and his social worker assistant for more detailed investigation.

When an official of the police, social welfare, or any other agency or private party calls the center to report a person who is considered mentally ill, and when this person is not yet known to the service, the psychiatrist on duty is bound to go out and investigate. He is not allowed to deal with such a case by telephone. In the middle of the night this may be a very heavy duty. It may take two or three hours, talking with the patient and the family. Yet it is the only way in which the psychiatrist can get the total picture promptly. On the other hand, his task may be finished in ten or fifteen minutes by a decision that this is a patient for the hospital.

It is absolutely necessary that the first "on-the-spot" contact with the patient is made by a psychiatrist because the responsibility for the decision and the authority required to back this decision, often under emotionally charged and difficult cir-

cumstances, can only be assumed by the expert physician. Although the psychiatric social worker will be valuable in carrying out the necessary case-work and further investigations, he cannot replace the psychiatrist. Experience has taught that such a service with too many social workers relative to the number of psychiatrists lowers its effectiveness to the point of becoming utterly useless. To the often-heard objection that there could not be enough psychiatrists to carry out this kind of work, the only answer is that one psychiatrist in this service has been found to be more effective than all the personnel of a fifty-bed ward.

Another important aspect of this service is its educational impact on the patient who must be educated to accept society, as well as on society and its representatives who must be educated to accept the patient. Every time the service comes into action, it teaches by example how to deal with the mentally ill patient. Usually the first emotion felt by the uninitiated bystander on seeing a mentally disturbed person is one of fear. Often he feels an urge to overpower that person in order to make him harmless. When a psychiatrist, properly trained for this work, enters upon the scene, he demonstrates by his own behavior that a certain situation can be changed by a certain attitude; that by treating the patient with understanding and honesty, *especially honesty*, and without showing fear or using force, it may be possible to reduce existing tensions in such a manner that they can be dealt with. The ubiquitous sensation-seekers soon disappear shame-facedly. Instead of seeing a screaming bundle of misery dragged to the ambulance or struggling between two policemen, they watch the patient calmly accompanying the doctor to the hospital or left at home when things have been smoothed over for the moment. It is obvious that such an occurrence cannot fail to leave a deep impression on those who witness it and is apt to change the layman's concept regarding mental illness more than any lectures or newspaper articles.

Asked about the problems involved in setting up a similar service elsewhere, Professor Querido emphasized that it should be started on a small scale and be allowed to grow gradually by itself. Although the need for such a service will usually be most pressing in the larger cities, it could be equally well established in rural communities. Because of the fact that the service must be ready to meet every personal emergency at any time, there must be no delay or bureaucratic machinery between the moment a problem comes to the attention of the service and the time when the first contact is made by the psychiatrist. Much will depend here on the relations between public authorities and various agencies already in existence. The personnel in this service must show a warm understanding of human needs and a matter-of-fact equanimity toward any of the multitude of incredible situations which may occur at any time.

It is immaterial whether such a service be set up by state, county, city or private bodies or organizations. All of them are possible and equally feasible. It may be run by one hospital alone, or by a group of hospitals; or private organizations and voluntary societies may unite to set up such a service. In the beginning it would be advisable for the service to limit itself to one or two groups of patients such as those suffering from alcoholism, suicidal tendencies, drug addiction, or the disturbed geriatric patient. The speed with which the service should be allowed to develop itself will depend on its initial success with these patients, the cooperation the service will obtain from other organizations, and the time it takes to overcome the opposition from the patients' families, hospital administrators, psychiatrists in private practice, and others.

Although it is naturally impossible to estimate the total number of hospital beds that have been saved by this service, or the number of hospitals that did not have to be built, or any of the other savings that have been made possible, the over-all success of this domiciliary system in Amsterdam (as well as in other Dutch cities and communities during the approximately thirty years of its existence) has been such that its principle warrants close study and investigation for eventual applicability in various American communities.

Investigation of treatment methods of mentally disturbed criminals.—A unique research program in forensic psychiatry has been in progress since April 23, 1955, at the Dr. van der Hoeven Clinic in Utrecht. On that day the clinic opened its doors to the first group of twenty mentally disturbed delinquents of all types, mostly psychopaths who had not responded to previous attempts at therapy and rehabilitation. In August, 1957, when I had an opportunity to visit the clinic and to learn about its operation from the clinical director, Dr. A. M. Roosenburg, and the socialogist, Dr. J. L. Jessen, the population of the clinic was close to

its maximum of 100 patients. Prompted by the steadily increasing cost of crime prevention and control and the urgent need of a more effective rehabilitation of mentally disturbed criminals, the idea for this particular clinic was based upon the hypothesis that behind the mask of the psychopath is hidden a deeply disturbed neurotic personality which is treatable by as yet unknown psychiatric methods. Thus, the clinic's goal is a form of neurosis center where psychopathic delinquents can be casually treated.

The very close relationship between the staff of the clinic and the patients who are organized in a patient government reminds one of the therapeutic community of Maxwell Jones' Belmont Hospital in England. The important difference, however, is that at the latter only neurotics are treated, while most disturbed criminals and some other types of mentally ill are not admitted. At the Dutch clinic only mentally disturbed criminals are admitted and studied. The importance of this difference is well demonstrated by the fact that the application at the Dutch clinic of Jones' principle of maximum freedom and minimum control proved to be a serious failure with dangerous complications. It had to be replaced soon by a so-called "controlled milieu" with a clear separation of the therapeutic activities and the administrative aspects of the controlled milieu.

In this in-patient clinic, emphasis is placed on individual and group therapy, as well as on training for work and industry. All patients belong to one or more therapeutic social groups, and group therapy sessions are held two or three times a week. There are daily staff meetings, and once weekly all patients meet with the professional staff consisting of four psychiatrists, four psychologists, six to eight social workers, one sociologist, two chaplains and one registered nurse, plus the administrative staff.

The development of attitudes, operative procedures, and therapeutic methods has been most difficult in the first year of this clinic's existence and it is expected to take at least another two or three years before the "children's diseases" inherent in such a novel experiment will have been overcome. It already has become clear that the therapy of these so-called "incurable psychopaths" brings along real dangers. For instance, in spite of many warnings and explanations, some of the less experienced social workers and nursing personnel got emotionally involved with some of the patients, which at times led to grave complications. Some of the seemingly normal patients were even able to deceive members of the staff and to involve them in erotic relationships which led to unpleasant consequences for the parties concerned. Some of these patients had, as a result, to be transferred to another institution, while others developed such tensions that they sought relief in escape.

Most important from the viewpoint of research were the consequences in those persons whose "mask of sanity" was being lifted by the process of therapy. Three distinct types of complicating reactions were observed. First, psychosomatic complications, *e.g.*, the reactivation of subclinical infections such as lung and kidney tuberculosis, aggravation of stomach ulcers and other similar conditions; second, panic reactions, personality disintegration and even psychotic reactions; and third, aggressive or escape reactions resulting in either physical aggression or actual escape from the unbearable situation. All these developments have stressed the need for the personnel to have a sufficient insight into their own emotional difficulties, to continuously exchange ideas and opinions with more experienced staff members, and also to observe and analyze constantly the manifold events occurring in this therapeutic community.

Obviously, merely a beginning has been made and much remains to be done in the development of psychotherapeutic and other treatment methods of those persons designated as criminal psychopaths. The problems to be solved are numerous. The magnitude of the problem of the criminal psychopath demands that the rest of the world follow closely the results of this courageous group of investigators under the leadership of Prof. Dr. P. A. H. Baan.

Work therapy in mental hospitals.—This form of therapy in the Netherlands deserves special mention because it differs in some important aspects from the system of work assignments prevailing in most American institutions. This particular system of work therapy was first introduced in the Netherlands at the Santpoort Hospital in 1926 by Dr. W. M. van der Scheer, its medical superintendent. He followed the method of Dr. H. Simon, medical superintendent of the German institution at Gütersloh. In many respects it must be considered the backbone of all forms of psychiatric treatment in the Dutch institutions, just as an occupation or profession may be considered the

backbone of an individual's adjustment in normal daily life.

Although in most Dutch, English, and American hospitals many of the less handicapped patients had been engaged in work activities for years, it was not until later that the experiences at Gütersloh revealed that work therapy could be practiced by all patients, even the most disturbed ones, provided that there is constant supervision and help from trained personnel which has to engage in the same type of work as the patient themselves. Moreover, the work itself has to be useful and must never be devised merely to keep the patient busy. In giving the patient a meaningful work assignment, his total condition has to be considered; and although it is necessary for him to work on a level within his capabilities, it must take some effort for him to accomplish the work. Usually the patient has to start with a simple form of activity and progress gradually to more difficult work. To change the patient's work assignments at the appropriate time, it is necessary that his accomplishments and his behavior are observed closely. For, if the patient is made to work above his level of ability, it will increase his resistance against reality and make him seek refuge in his psychotic experiences. If, on the other hand, he works below his level, it will be too easy for him and he will do his work automatically, giving him the opportunity to wander off into his pathologic dream life.

To provide this close supervision, it is necessary that patients work in groups which are not larger than approximately fifteen patients. The group may be directed by a nurse or psychiatric aide, an occupationally trained employee such as a gardener, electrician, baker, or even by another patient who naturally must be more nearly well and capable than the patients in his group. It is furthermore necessary that the medical staff receive regular reports about the achievements, behavior and attitude of each patient engaged in work therapy. This is usually done through weekly reports. The institution must have a rich variety of work activities at its disposal in order to provide each patient with a suitable work assignment which takes into consideration his background, experience, interests and present mental condition.

It is advisable for the group leaders to be trained in the work that the patients in their group perform in order to be able to give them the maximum assistance. Many of the Dutch hospitals provide special programs for psychiatric aides, registered nurses and student nurses to be trained as work therapists. Santpoort, for instance, offers the student nurses courses in handicrafts, sewing, darning, crocheting and knitting. All personnel at this hospital are required to get at least one year of actual work experience in one or more of the crafts or work assignments employed at the hospital, be it with the lawn crew, tailor shop, toy repair shop or other work shops. It is also advisable, though not absolutely necessary, that adequate work space be provided. Such was done recently at the Santpoort hospital when a new work therapy building was erected with separate rooms for wood work, shoe repair, book bindery, tailor shop, paint shop, toy making and toy repair shop, and various rooms for making brushes and sweepers, rushing baskets and bottoming chairs, mat making, weaving, knitting and crocheting. The principle that all work has to serve some useful purpose—that is, it must never be designed for the sole purpose of keeping the patient busy!—is adhered to rigidly at all levels, even the work of the most deteriorated patient. So, for instance, the simplest type of little productive craft work which I observed was fluffing rope; several groups of chronic schizophrenic patients were occupied with this work, the end product of which is used to fill, together with tar, the cracks in ship hulls.

All actively engaged patients receive a weekly monetary reward up to a maximum of 2½ guilders. The size of this reward, which is not a salary, is determined by the psychiatrist in charge of the patient. He relies on his own observations and the reports he receives from the group supervisors about the patient's achievements and demonstrated interest, as well as his social behavior in the group. The patient gets paid in regular currency if he is able to handle it. If this is doubtful, he gets tokens which he can use just like currency in the hospital shop—or throw it into the water if he is inclined that way. The patient is free to spend the money earned in whatever way he pleases. At the same time it presents him with an opportunity to learn to save and thus to postpone his urge to spend. However, he is never forced to save.

This system of monetary reward for work well done has been proven to be of great importance in the over-all therapeutic program of the patient. The following pedagogical principles of such a system are easily detected: (1) The recognition of the value of the patient's work, (2) The recog-

nition of his good behavior, (3) The opportunity to teach him that good behavior is at least as important as his work achievement, (4) The learning to handle money or tokens by spending wisely and usefully or by saving so that later he may purchase larger and more expensive articles such as shoes, suits, books, and so forth.

The finished products of the patient's handiwork are sold in the attractive hospital shop, but not outside of the hospital. Their price is comparable to prevailing retail prices in the community, and "dumping" never occurs. These articles are always in great demand, for naturally each piece has been given much individual attention and is of excellent quality. All money from sales in the hospital shop is used for the purchase of new supplies of raw materials, as well as for the rewards distributed each week to the patient-workers. Deficits in this "work therapy fund" are supplemented by yearly or biennial appropriations. It is worthy of note that legislators in the Netherlands have never been stingy with their appropriations to this fund, that Dutch manufacturers and retailers have never objected to the sale of articles produced by the patients, and that Dutch farmers have never considered the hospital-run farms as unfair competition. Such potentially short-sighted views never developed in the Netherlands, because members both of public and private industry, learned early that the long-term savings inherent in this form of work therapy would be much greater in terms of shortened hospital stays than any small savings which could be realized by other systems of work assignments, or lack of a system.

For a better appreciation of this Dutch system of work therapy it is well to digress for a moment and to analyze the system of combined industrial and occupational therapy as known in most American state hospitals. In America the patients are expected and urged to engage in some type of work for two main reasons: (1) because "it is good for the patient" and because "he must be occupied," and, (2) because the hospital cannot be run without his help.

A sick person who is disturbed in his relationship to himself, to society or to both, will find it difficult to understand why it is so good for him to work. Usually he became ill in spite of a lifetime of work, and he fails to see why working should contribute to his recovery.

Asking him to work for the good of the hospital is tantamount to calling upon his sense of duty and obligation toward the common good. If he does not respond to this motive, it is usually because he is too sick to be concerned with the welfare of others; yet his refusal will cause him to experience feelings of guilt and shame. If he does accept the invitation to work, it is often because this work offers him an opportunity to expiate his feelings of guilt or to counteract feelings of worthlessness. This is an excellent indication for prescribing work therapy in many patients, but sooner or later, these patients, too, realize that by working in the hospital industries they are paying off a debt to the state which is giving him something for nothing, or at least for less than cost, namely, psychiatric treatment in addition to room and board. The ensuing psychologic reaction is obvious: deepened feelings of inferiority for having to accept charity.

But by giving him a chance to work for a monetary reward—the closest one can get in similarity to the salary earned for work done in society—one obviates the harmful psychologic effect associated with being left no alternative but to accept charity. Now the patient works for money with which he can buy his own cigarettes, candy or soap; he can write as many letters as he wants, since he is not limited by the hospital's gift of one stamp per week. He has tangible proof that his work is valuable, that he is not made to do things just to be kept busy or out of trouble and mischief. He gains pride and self-confidence when he sees that he is able to produce something useful and wanted by others, for the product of his hands is offered for sale in the hospital shop and sold sooner or later. When the patient has been assigned to a hospital industry, such as the laundry or the bakery, he may not know that this is the best place for him from a psychiatric point of view, but he will know that his work is as valuable as that of the patient in the toy shop, because he can earn as much as the other. He is not made to feel that he owes it to the state to work—if so, why should it pay him a reward?—although this may be hinted at if indicated for therapeutic reasons, for example, in guiltridden, self-accusatory depressed patients.

Later, when the patient begins to realize that he actually produces much more than the value of the reward, it means also that he is well enough to appreciate values and to foster higher qualities in himself, such as a sense of obligation ("the money from the sale of my handiwork helps to

buy raw material for other patients") or gratitude to the hospital staff for taking care of him ("by working in the garden or the machine shop I help them to operate the hospital").

It should be mentioned that in some Dutch mental hospitals, industrial concerns provide orders for various types of work, such as assembly work, sorting and brush making. This work is performed for a fixed price, but the time needed to accomplish it and its total amount is determined by the medical staff. Work for outside industries is an exception at Santpoort because it is felt that the hospital becomes too dependent on the industrial organization. Moreover, little of this type of industrial work is suited for work therapy because mechanical routine jobs are indicated therapeutically in only a small number of cases. And finally, in too many forms of industrial work, there is not enough opportunity for inventive creativeness on the part of both patients and supervisory personnel.

Undoubtedly much of the therapeutic value of the Dutch system of work therapy lies in the fact that the patient gets considerable individual attention. The empty dormitory wards in the Dutch mental hospital are a striking sight to the person who visits during the morning or afternoon hours. So are the many busy groups of patients engaged in different activities, the variety of which is not only stimulating to the patients themselves, but also to the supervisory and actively participating personnel. These sights are in striking contrast to the still too familiar sight of wards in some American hospitals where patients hang around in idle boredom, while the ward personnel does not appear to know what to do with its time. The visitor schedules are also geared to the importance of this superbly organized system of work therapy, the visitors being encouraged to come only in the early evening hours, or being limited to visits on one or two afternoons a week.

Limits of space preclude mention of those aspects of work therapy which are similar to those existing in this country, such as the giving of other rewards, more liberty and responsibility, independent work assignments on responsible posts, nor the many other therapeutic activities, including the physical "movement therapy," which are smoothly integrated with the highly perfected system of work therapy. (In 1956, 87 per cent of the total Santpoort hospital population participated, while in 1955, the total value of articles produced and income for services rendered amounted to almost 54,000 guilders.)

Finally, an over-all comparison between Dutch and American mental hospitals may be of some value. The medical staffs of the Dutch hospitals, though small in absolute numbers, were found to be of the highest caliber, since all members have been fully trained in psychiatry after completion of their medical education. Many hospitals employ physicians who as part of their psychiatric training have to spend six to twelve months in a mental hospital. Other medical specialists are employed also, although in reduced numbers; for instance, Santpoort has, in addition to six qualified psychiatrists and neurologists, one specialist in internal medicine, one in pathologic anatomy, one psychologist, one biochemist and one electroencephalographist. Prestige as well as professional standing were found to be high, both in the eyes of their medical colleagues and in the eyes of the public. Undoubtedly much of this prestige is due to the fact that, contrary to the custom prevailing in many of our state hospitals, the Dutch hospitals will not employ physicians retired from private practice or those with limited or suspended license to practice medicine because of alcoholism, drug addiction, unethical behavior, personality problems, or other reasons. Although the purpose of the employment of such physicians with personality difficulties, namely, the rehabilitation of these physicians, is laudable in itself, such employment has, in my opinion contributed significantly to the inferior standing and lack of prestige which the state hospital physician has in the eyes of his colleagues in this country. Besides, such rehabilitation could be carried out much better and under much more intensive supervision at university rather than at state mental hospitals.

Unlike prevailing conditions in our civil service system, no physicians in the Dutch mental hospitals are called psychiatrists unless they have completed their specialty training. Our practice in this country of providing a non-trained physician with the title of psychiatrist after only one year of work in a state hospital has done much to give the false impression to the public and the legislative bodies that our state hospitals have an abundance of psychiatric specialists.

Salaries of psychiatrists in Dutch mental hospitals were found to be comparable to ours: that is, too low as compared to incomes in private practice. However, these low incomes are largely

compensated for by much higher professional standards in these hospitals, greater opportunities for research and for application of highly specialized psychiatric treatment methods. Often this is not the case in America where the non-qualified physicians, as well as their colleagues with limited license, pull down the level of scientific achievement. This superior professional standing in the Dutch mental hospital was well reflected at the Santpoort hospital in the thorough evaluation of the newer tranquilizing drugs, emphasizing quality rather than quantity. These drugs have been, and are, investigated only in comparatively small numbers of patients; yet, the psychiatrist follows and studies each patient in a more intensive and thorough manner than is possible when one employs an extraordinarily large group of patients. Complete reports of drug effects are made for each patient under investigation, and these are gathered together by the medical director and put in print for the purpose of reference and study rather than of publication. Consequently, the conclusions of these investigations bear much more weight than the mass investigations customary elsewhere, for such mass investigations necessarily lack the thorough study of factors other than the drugs themselves which may also have a bearing upon the patient's response to the drugs.

Reflecting on the merits of the Dutch system of work therapy, it occurred to me that if this system had been developed in the United States, the Dutch and other Europeans would undoubtedly have considered this as another typical example of the power of the American dollar. Most likely they would not have given it another thought. The fact that the reverse took place should make us pause and ask ourselves how this system might enrich the particular therapeutic programs in our state hospitals.

My Dutch colleagues expressed, not unexpectedly, surprise at the glaring discrepancy existing in this prosperous country between the magnitude of the problem of mental illness and the relatively slight financial efforts to cope with it. Only a historic review of the growth of American mental hospitals with their emphasis on custodial care rather than treatment, and an explanation of the particular place these hospitals take in American culture and political structure made these physicians see why it had not been until after World War II that an outraged public had demanded a major overhaul of the "snake pits," and Federal and state agencies had begun to see the need for greater financial support. They found it hard to believe that many a dedicated medical superintendent had fought for this in vain for decades, frustrated as he had been in all his efforts by indifferent politicians. They came to realize that it would take many years of steadily increasing appropriations, as well as a basic change in mental hospital administration, before an adequate number of trained psychiatrists would be attracted to state hospital employment in order to treat patients, to conduct research and to train other personnel.

At the same time, these Dutch psychiatrists came to realize and appreciate the tremendous importance of conditions they had come to accept as a matter of course in their own countries. These are: freedom of interference by political parties or incompetent persons in the administration of mental hospitals, and a balanced value system of giving priority to medical, nursing and other personnel rather than to provisions for better-than-average food and clothing, and thus a correct emphasis on psychiatric treatment rather than on physical comfort.

In this regard I hopefully predicted to my colleagues in the Netherlands that the next several decades in America would witness a tremendous progress as several state governments had already begun to make a concentrated effort to effect a shift from custodial care to active psychiatric treatment, while in the past several years Congressional appropriations had been increased yearly to meet the problem on a national basis.

Yet, from what I observed in the Netherlands it is obvious that money alone will never fully accomplish this tremendous task. Moral, social, scientific and spiritual forces will have to lend a helping hand. Fortunately for the future of our mentally ill sincere, unselfish, competent, and non-partisan persons in some states have already begun to realize this and are meeting the challenge of more intensive psychiatric treatment by studying and suggesting changes in commitment laws, in appropriation procedures, in civil service regulations, by proposing reduction of political control in favor of medical administration of state hospitals, and by freeing medical staffs from unnecessary encumbrance and restrictions.

Blue Shie Its

MM

• Here is a summary of the history and principles of the Minnesota Blue Shield from its beginning to the present written by a physician who was, and is, active in the total planning.

THERE is so much misinformation and lack of information about Blue Shield that a few words might not be amiss. The basic principles are so simple and straightforward that when they are known, usually they are easily accepted and enthusiastically supported.

The Minnesota Medical Service, Inc., began operation in November 1947. Before that date, however, there is quite a history which has a bearing on subsequent history and progress.

In 1944 we had a rather socialistically-inclined government. In fact the Federal Bureau of Investigation was busily engaged in investigating medical societies here and elsewhere. Earlier in Washington, D. C., such organizations had been accused of violating the Sherman Anti-Trust Law and had been found guilty. They were even classed as a business and not as a profession! So, when Dr. Richard Crammer in Minneapolis and I in Saint Paul conceived the idea of a medical service plan patterned after the Blue Cross, we had these previously-mentioned conditions in mind. We started at the same time, unknown to each other.

My idea was to start in Ramsey County and spread from there, as the Blue Cross had done. So I investigated and, in fact, on February 23, 1942 was given an evening by the Ramsey County Medical Society to present two out-of-town men—Mr. Mac F. Cahal, then of Chicago, and Dr. Jason Hannah of Toronto—to talk to us about their experiences and to give us the benefit of their advice. The subject of the evening was entitled "Pre-payment Plan for Medical Care." The Ramsey County Medical Society was so interested they authorized $500 for further research. We were soon ready to go ahead.

In the meantime at the annual meeting of the Minnesota State Medical Association in Rochester, Dr. Crammer introduced a resolution in the House of Delegates for a Service Plan and it was passed *unanimously.* We in Ramsey County were asked to "hold everything" in view of the plans for state-wide participation and coverage. This we did.

As usually happens, if one evidences interest in a subject it means more work. So I was included in the organizing committee. We went to Detroit to visit the Michigan Plan, to California to visit that plan, and to Boston to visit the Massachusetts Plan. The Committee, consisting of twenty-four men, met and the fight was on. Everybody agreed that such coverage was necessary, mostly because

Saint Paul, Minnesota

of the threat of socialization of medicine—*a real threat at that time*. It was felt that if we, the doctors of the state, offered a good prepayment plan, a method of budgeting for medical expenses, it could go far to stymie the trend toward socialization. The big argument was whether we should hire insurance companies to do it and we specify the terms, or if we should do it ourselves. Previous to this, insurance companies had been approached and all turned it down as a bad and uninsurable proposition—"we can't risk our policyholders' money on such a scheme." No comprehensive prepayment medical coverage existed before Blue Shield paved the way.

Finally, after days of meetings and much talk, it was decided nineteen to five that we, the Association, should go it alone. (The irreconcilable minority, favoring Insurance Companies, organized and took pot shots at us for a long time.) The money for the previous investigation, amounting to about $7,500, was furnished by the State Medical Association.

In 1945 the Legislature, prodded by Mr. F. Manley Brist, then attorney for the State Association, passed the special enabling act which created the Blue Shield. It stated that any twenty-one, duly-licensed and qualified, practicing Doctors of Medicine could start such a company, but that it had to have a minimum of $25,000. That looked formidable. Our critics said we should have $100,000. But with a little publicity, we sold notes of from $25 to $500 to members of the medical profession, and in a short time raised over $88,000, with much more being available. Response came from 920 physicians. The flood of checks was very inspiring. Criticism stopped at once when it was seen how easily and quickly the money was being raised.

At the suggestion of The Council it was decided to divorce the Blue Shield from the State Association as much as possible in order to avoid any legal entanglements. Blue Shield was an absolutely independent corporation. That is why the Blue Shield is a separate corporation and why the original Board of Incorporators (twenty-one men, two from each district and three at large) elects the Board of Directors from its membership (eleven men, one from each Councillor district and two at large). This division was made to keep the representation equal throughout the state and to avoid having domination by any part of the state. This was in response to a promise made to the Legislature, and we have tried to live up to that ever since.

We lifted the list of payments *en masse* from the Massachusetts Plan. They in turn had had specialty groups present figures from their respective members and had developed their list of payments from that. We asked the Blue Cross to run it for us until we could develop our own machin-

ery. They did and we prospered. We paid back the State Association its $7,500 and each and every doctor got his money back with 4 per cent interest. *So we owed no one.* In fact, the only money now in Blue Shield is that paid in by the policyholders. In remembering the long hours of work during those days I wonder, now, how we did it. Meetings lasting from two or three in the afternoon to one, two or three o'clock in the morning were the rule. We were all amateurs and had to learn the hard way. We learned "to make haste slowly." We knew it was not our money that we were handling and that insurance companies (and others) figured Blue Shield, being run by amateurs, would fall flat on its face.

The first premiums were $1.00 per individual and $2.25 per family, per month. We sold only in groups to start with. The first group was the Farm Bureau Federation with 40,000 people. We have been grateful to them ever since. Then we spread out.

In 1950 Dr. Edwin Simons of Swanville was asked to be our Executive Director on a full-time basis. He did a splendid job and still does. Then in January, 1954, we cut loose from the Blue Cross and now run everything ourselves except the actual mechanics of the operation and sale of policies. Today we process over 1,800 claims every working day. We paid out almost $7 million to the doctors of the state in 1956, over $9 million in 1957, and have paid over $40 million since 1947. Over 880,000 people are now covered. In 1954 the "B Plan" was presented, after over two years of study and planning had gone into it. Since the Blue Shield had started, inflation had occurred, so that by that time, only 20 per cent of the people of the state were covered. The Board thought everybody would welcome the changes incorporated in the "B Plan"—a 50 per cent increase in premiums and a 50 per cent increase in payments to doctors. So the controversy which developed in Duluth was a surprise. However, wisdom prevailed and the "B Plan" remained in effect. It now covers over 90,000 people. It is a self-supporting part and is doing well.

The Blue Shield is a going concern. But do you know *that it is not insurance?* It looks like insurance, *but it is not!* Six State Supreme Courts have so decided. It is a *pre-payment service plan* to help people to budget in advance for medical service. That is why we are *not* under the Insurance Commissioner, who is an *appointed* officer. But the Insurance Commissioner inspects our books and records once a year and makes suggestions. When we want to make a change in premiums or benefits we must receive the approval of the State Attorney General. This is a nice arrangement and so far has worked well.

Payments to doctors have been increased steadily year by year as fast as we could seem to afford it. Over 250 such increases have been made. We have met with the specialty groups for the last three years and have tried to incorporate their suggestions into our thinking. Utilization had increased and with increased payments the margin between income and outgo had narrowed down so much that something had to be done about it. So again, after long and careful deliberation, it was decided to increase our premiums by 15c per month for the individual and 50c for the family.

This is our *second* rate increase in nine and one-half years, and went into effect on July 1, 1957. This improved the financial structure and made possible more increased payments. That should be pleasing to doctors and subscribers alike. Nowhere else does the subscriber get as much for his money. The overhead remains at about 10 per cent so the subscriber has 90c out of every dollar available for payments.

Minnesota ranks about eighteenth in population of all the forty-eight states and our Blue Shield is tenth in size of all the similar organizations in the United States. The Blue Shield has about $5 million in government securities and other investments. The income from this is used currently to help make payments and is not allowed to accumulate. The Board thinks that the money is the subscriber's and should be used for his benefit.

There are about sixty-eight Blue Shield Plans throughout the country and they have organized a national organization. This organization was formed for three reasons:

(1) To talk over mutual problems and to exchange experiences.

(2) To take over national accounts, such as General Motors, Ford Motors, U. S. Steel and so on, who have many employes throughout the country and who want uniform coverage.

(3) To take care of national advertising. It has been found that this costs so little, and the benefits are so great that it has paid to advertise not only nationally, but locally as well. Advertising, for instance this year, was 22 cents per contract

per year. I mention this because the question has been asked if Blue Shield couldn't pay more if the advertising was cut out. This amounts to $64,000 per year or .5 per cent a month per contract.

In addition, there is a district organization, composed of Plans from Nebraska, Iowa, North Dakota, Wisconsin and Minnesota, organized for the same purpose as the national one, but on a more limited scale. This is the 10th District group.

What is the Future for Blue Shield?

The Blue Shield has carried the medical profession away from a disastrous situation—government insurance. But, there is still grave danger of getting back into it again. That danger is far from over. In the days before the depression and the threat of socialization in the 30's there was a good doctor-patient relationship with no concern for health insurance or Blue Shield. Doctors liked to practice medicine with no government interference. This was the relation of *one* doctor to many patients. Most of them paid, some paid a little, and some not at all. But in those days it balanced off and no one worried much about it.

Then came the depression. The doctor took care of as many people as ever, but the paying part dwindled fast. It is well known that the low income group need the most care per capita for obvious reasons. The situation got worse and worse.

Doctors then turned to insurance companies and this is what happened. Some years ago Dr. Elmer Hess, past president of the AMA said:

"Several years ago, before there was any idea of a Blue Shield and there was not much of what is now known as the Blue Cross, I was among a delegation of physicians who went East to confer with high officials in the insurance industry. Our mission was to try to encourage the insurance companies to enter a new field of endeavor that some of us thought would soon become popular and also serve a socio-economic need. That mission did not provide us with too much fondness for the so-called big insurance interests. My colleagues and I were sent by the then officials of the AMA to try to interest some high officials of the insurance companies to enter the field of hospital expense and possible surgical expense benefits. We had an audience that was dignified. With firmness that was equal to the dignity with which we were received, we were told that we were proposing something about which little was known. Moreover, the insurance men implied there were other problems of pressing importance and there was little reason to enter uncharted seas and risk unnecessarily policyholders' funds entrusted to them for safekeeping."

Well, you see, as I mentioned before, the doctors tried, but the insurance companies said "no" and for good basic reasons. These are the *principles* underlying all risk coverage:

(1) The rate must vary with the risk, (2) The rate must be equitable, (3) The risk must be certain for the group, but uncertain for the individual, (4) A person *must not benefit from the loss,* and (5) The loss must be sizable and infrequent.

The insurance companies saw the risk was predictable and that the risk was enormous. The people about whom the doctors were most concerned were those to whom they were offering care and free care at that. These people were sick and had to be taken care of and the doctors did it. The doctors were not asking the insurance companies to take care of the well, but to help to care for the sick. Those who needed it got it, but couldn't pay for it.

Something had to be done, and the Government offered to do it. The situation was rather desperate. So community coverage—Blue Shield—was the answer and still is. This means good risks and poor risks—all covered. The good ones carry the poor ones. (Complete coverage was tried in Michigan and Massachusetts and abandoned in 1942 as being unrealistic because at that time it would have cost $10.06 per month per person. A complete coverage means house and office calls and all medical services—diagnostic and therapeutic.) In 1945 and 1946 when we were starting medical service programs, we were relatively inexperienced. The basis of Blue Shield was limited coverage to start with, and a spread from there as experience warranted.

The Blue Shield (1) is organized in the community interest; (2) is sponsored by physicians; (3) is non-profit (no stockholders, no dividends); (4) is low in cost of administration (10.1 per cent now); (5) has community enrollment (good risks and poor risks alike, to spread costs); (6) has the same rate for any age and either sex; (7) has no increase in family rate because of growth of family (Blue Shield covers any sized family without any increase of premium; a family is a man and wife with no children, or any number of children); (8) has coverage *throughout life* (any person now covered may keep his coverage indefinitely if he keeps up his payments).

. . . *and just as important.*—(1) Fee for service.

(2) Free choice of physician. (3) No third-party interference.

This worked fine because of the principle of integrated risk. Sick people were protected and well persons covered. Then employers began to contribute and they wanted to vary coverage with their experience with "good" groups paying less and groups with higher utilization paying more. This breaks up the community risk idea. The trend towards this is increasing. As one man (Carl Fischer, Professor of Insurance at the University of Michigan) said, "Each company endeavors to secure as favorable a portion of the community as practicable . . . ." Now, the danger is that the good risks are being pulled away. The insurance companies are under-bidding for good risks and refusing to cover the poor risks. This destroys the community concept which is basic with Blue Shield.

The Health Foundation indicates that throughout the nation only 41 per cent of persons with incomes under $3,000 are covered and 80 per cent of families with an annual income of $5,000 or over. Poor risks can't support themselves. Therefore, again I stress the importance of community coverage.

A new factor is developing and the voice of the doctor is being stilled by attempted third-party domination—*employers* who pay and *unions* which dictate terms for employes by demanding broader and broader coverage of the individual.

Structure of Blue Shield

We now have (besides the Board of Directors consisting of eleven men, all Doctors of Medicine):

1. The Board of Incorporators. At first this consisted of twenty-one men chosen by The Council. The Board of Incorporators is being increased as rapidly as possible in multiples of nine in order to maintain the relative representation throughout the state and to keep faith with the Legislature. Nominees are appointed by The Council and elected by the Board. It is hoped that eventually the Board of Incorporators will be about as large as the House of Delegates and will include every component society in the State.

2. An Executive Committee composed of four members of the Board of Directors which meets between meetings of the entire Board.

3. A Finance Committee composed of three members.

4. An Enrollment Committee, of four members.

5. A Medical Advisory Committee.

6. A Liaison Committee.

Then we have organized:

1. A special Advisory Committee on Fees which has met with specialty groups to talk over their recommendations, most of which appear in our new schedule of payments.

2. Physicians' Review Committee, which consists of a member from each specialty group and two from the general practitioners' group, to review unusual claims.

The present plan is to draw on the Board of Incorporators to serve on these committees. This still has not been completely worked out.

We have now decided that physicians serving in hospitals and paid by them such as pathologists, roentgenologists and physiatrists are going to be paid by the Blue Shield. We feel that these are specialists in medicine and should be paid by Blue Shield and not by Blue Cross. This will increase the number of beds available and cut down on the expenses of Blue Cross a great deal.

Where You Come In

What can *we,* members of the medical profession in Minnesota, do about Blue Shield? *First,* we can become informed. The biggest difficulty is *lack of interest* and *lack of information* on the part of the average doctor. He has *opinions* but not *facts.* This is the universal complaint of those concerned with all Blue Shield plans. *Second,* we can *stress service benefits.* We can tell the people that *immediately apparent* benefits offered by insurance companies will not compare with the long-range benefits of Blue Shield, for example, subscribers can continue *after age sixty-five.* This non-cancellable feature is to be stressed. We can tell the people that *no one has had his Blue Shield policy cancelled because of heavy usage.* We can tell the people the greater proportion of good risks are in the middle income group, and if you sell them the idea of *service benefits,* Blue Shield will prosper. We can tell the people that Blue Shield pays out a larger proportion of their premium dollars in benefits than any insurance company.

Tell them of your plan, *one plan, the community plan, the Blue Shield.*

● *The creation of arteriovenous fistulas in children to cause lengthening of a short leg is but one of the many facets covered in this paper. The orthopedic surgeon, as well as any physician who deals with injured extremities, is particularly concerned with vascular trauma, because injuries to blood vessels can complicate what otherwise would be a relatively simple problem in orthopedics. This paper summarizes orthopedic interest in vascular surgery.*

Peripheral Vascular Surgery from the Standpoint of the Orthopedic Surgeon

JOSEPH M. JANES, M.D.
Rochester, Minnesota

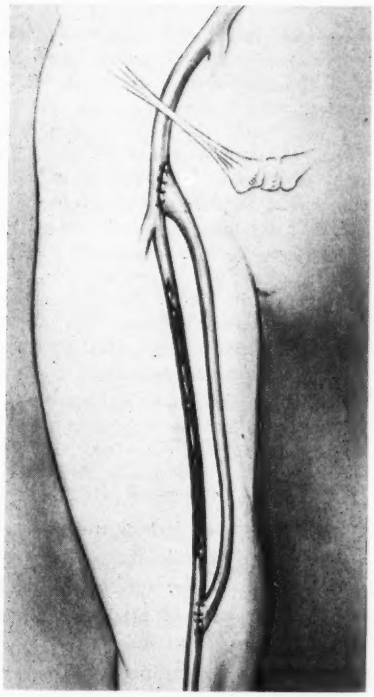

Fig. 5. Diagrammatic sketch of the bypass procedure.

SINCE World War II, renewed interest has arisen in vascular surgery in general. Orthopedists are particularly concerned with vascular surgery as it applies to the extremities with respect not only to traumatic conditions but also to other entities that shall be discussed in this presentation.

The importance of surgical treatment of blood vessels in orthopedics was well stated by Murray[1]: "Bones, muscles and nerves are necessary for function of an extremity but without blood vessels none of these will survive or function." There are three main reasons why orthopedists should be able to recognize and deal with almost every condition that affects the vascular system of the extremities. These are (1) diagnosis (when something is wrong with an extremity, the patient is often seen by an orthopedist), (2) treatment (if an operation is required, it is the orthopedist who should be most familiar with the anatomy of the extremities) and (3) aftercare (the orthopedist is most familiar with rehabilitation of the extremities).

From the Section of Orthopedic Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

Congenital Vascular Problems

Of all the vascular lesions in the extremities concerning orthopedists, the congenital types are probably the most difficult with which to deal.

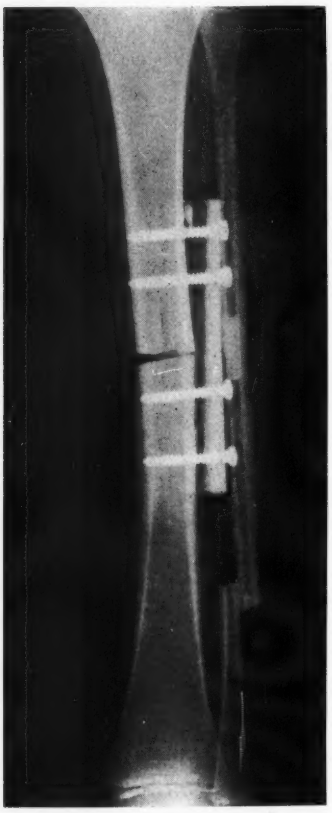

Fig. 1. Anteroposterior roentgenogram showing homologous onlay graft to tibia after resection of 4 cm. of that bone and osteotomy of the fibula.

Congenital Arteriovenous Fistula.—This condition is usually made manifest by an increase in the length and girth of an involved extremity when compared with the contralateral limb. The fistulas are usually multiple and, therefore, it is difficult to treat them surgically. Arteriography may be of use in the diagnosis. If these lesions show any localization at all, every effort should be made to remove them, even if removal requires multiple procedures. Amputation occasionally may be necessary.

The following concerns a patient who had congenital arteriovenous communications about the right astragalus.

A girl, aged eleven years, came to the Mayo Clinic in September, 1950. Her right lower extremity was 2.5 cm. longer than the left. The typical bruit of an arteriovenous fistula was heard just below the right ankle. The arteriogram showed arteriovenous communications about the right astragalus.

Three separate surgical procedures were necessary in order to remove all of the fistulous tissue. Stapling of the upper right tibial epiphysis was done in January, 1951. By June, 1952, the right lower extremity was only 1.3 cm. longer than the left. In 1955, at age sixteen, the right upper tibial epiphysis had closed; no thrill or bruit was present in the right foot, and the lower extremities were equal in length by direct measurement.

Even when it is impossible to remove all of the arteriovenous communications, stapling or epiphysiodesis may be done to check the abnormal longitudinal growth of bone.

Arteriography occasionally demonstrates that the arteriovenous communication is single. This is a fortunate circumstance in that the lesion may be removed by quadruple ligation excision or block dissection of the lesion.

An eight-year-old girl came to the clinic because her left lower extremity was 4 cm. longer than the right. The veins of the left leg were distended, and a port-wine stain was present over the heel. A to-and-fro murmur was heard over the lower portion of the left popliteal space. Roentgenograms of the left tibia showed a cystic zone in the middle portion of the shaft. An arteriogram showed what appeared to be a fistulous communication in the medullary cavity of the midtibia. There also appeared to be increased vascularity in the posterior portion of the foot. Resection of 4 cm. of the tibia, including the site of the fistula, was done, and the fibula was osteotomized, allowing the fibular fragments to override. A homologous tibial bone graft was applied to the tibial fragments (Fig. 1).

The bruit was abolished and the discrepancy in leg length was corrected at the same operation. It is possible that this patient may have trouble in the future because of the vascular anomaly in the foot.

As has been mentioned, amputation occasionally may be necessary, especially if an ulcer develops that refuses to heal. If the congenital arteriovenous communications are confined to a finger, amputation of the finger is all that is required. Amputation must, of course, be proximal to any arteriovenous communications. This may not be possible in diffuse disease that extends from an ex-

tremity into the trunk. Patients are encountered in whom the differentiation between multiple small arteriovenous fistulas and diffuse hemangiomas is extremely difficult.

Hemangiomas.—These are benign soft-tissue tumors of endothelial origin composed of blood-vessel elements in varying states of maturity. They are usually thought to be congenital and are commonly found in the extremities. They may be discrete or diffuse. Histologically, they are capillary or cavernous. Of ninety-three hemangiomas of the extremities reviewed by Johnson and associates[2] at the clinic, twenty were diffuse and seventy-three were discrete. In patients having discrete tumors, pain and the presence of a tissue mass were the commonest symptoms, while the presence of a palpable tissue mass was the commonest physical finding. In patients with diffuse tumors, pain and swelling, with obvious cosmetic changes, were the commonest features of the history, while a tender tissue mass was most often found on physical examination.

Roentgenographic changes that may be noted include the presence of a soft-tissue tumor, generalized osteoporosis, periosteal thickening, bony erosion and the presence of phleboliths.

All ninety-three patients reported on by Johnson's group underwent surgical excision of the hemangiomas. After operation, 75 per cent of those whose tumors had been discrete became symptomless but all of those whose tumors had been diffuse still had symptoms, illustrating the difficulty of treating diffuse hemangiomas surgically.

Other types of treatment for hemangioma have included (1) injection directly into the tumor of sclerosing agents such as a solution of urethan and quinine hydrochloride and a 50 per cent solution of glucose, (2) topical application of agents such as carbon dioxide snow, (3) roentgen and radium therapy (although it is doubtful if this should be used in children) and (4) electrocoagulation.

Traumatic Vascular Conditions

It is in the field of trauma that the relationship of the arterial supply to surgery of the extremities is most vital to the orthopedist. Although most of the vascular lesions due to trauma are seen in wartime, physicians are seeing more and more of these problems in civilian life due to increased mechanization and high-speed travel, not to mention accidents with firearms.

The four cardinal principles in dealing with a peripheral arterial emergency are (1) do not delay, (2) do not heat, (3) do not elevate and (4) do not refrigerate.

Supracondylar Fracture of the Elbow in Children.—As in all fractures and dislocations of the major bones and joints of the extremities, the status of the nerve and blood supply distal to the injury should be determined immediately. If the radial pulse is not palpable after a supracondylar fracture, it may become so after closed reduction of the fracture. If this is the case, routine treatment may be followed, care being taken to watch the state of the circulation closely for at least 48 hours. If the pulse does not return after manipulation or if it disappears after manipulation and signs of early ischemia begin, such as pain, swelling, coldness, cyanosis or pallor and loss of finger motion, definite action is indicated. If evidence of circulatory embarrassment persists after the flexion of the elbow has been lessened and the constricting bandages removed, the lower portion of the brachial artery should be explored. Some surgeons[3] advocate preliminary traction and sympathetic block, but I sleep better when I know that the cause of the trouble has been eliminated. On exposure of the brachial artery, one of the following conditions may be found: (1) the artery may be in spasm, (2) it may be contused, with resultant thrombus formation, (3) it may be lacerated or (4) it may be completely severed.

If the artery is in spasm, bathing it with warm isotonic solution of sodium chloride or procaine hydrochloride or wrapping it with a sponge soaked in a 2.5 per cent solution of papaverine sulfate[4] often brings about relaxation of the spasm. If the artery has been contused so that the intima has been damaged, leading to thrombus formation, arteriectomy is advised.[5] My associates and I have not found it necessary to restore the continuity of the artery in this region; instead, simple ligation of the divided ends of the artery has sufficed, because the collateral circulation about the elbow is adequate.

If the artery has been lacerated by a spicule of bone, it is better to divide the vessel completely. Complete division is preferable because the vessel is small and suturing of the laceration would reduce the size of the lumen, thus predisposing it to the formation of a thrombus. If the artery has been divided completely, each end is ligated. We

prefer to use transfixing sutures of number 0 braided silk. If the artery has been lacerated or completely divided, there will, of course, be a hematoma to be evacuated. After the artery has been dealt with, the fractured bone usually can be held in place without internal fixation. The wound is loosely closed, and a massive dressing is applied with a posterior plaster splint to hold the elbow joint at an angle of about 90 degrees.

Rupture of the brachial artery may occur as a result of dislocation of the elbow.[6] This situation is dealt with as has just been mentioned. After vascular injuries in the region of the elbow, or anywhere in the extremities for that matter, the postoperative blood pressure should be maintained at or near a normal level. Heating or elevating the involved limb should be avoided. A heat cradle over the abdomen, together with the administration of papaverine or alcohol, may be utilized to advantage in promoting collateral circulation, providing the blood pressure is maintained at a normal level. Alcohol should not be given to children. Paravertebral sympathetic block is transient in effect and is not considered necessary, as pointed out by Linton,[7] since division of the artery in itself accomplishes an effective periarterial sympathectomy, to which sympathetic block or sympathetic ganglionectomy as an emergency procedure adds little benefit.

Dislocation of the Knee.—This occurs more rarely than does dislocation of the elbow. When anterior or posterior dislocation of the knee occurs, the popliteal vessels are in grave danger of rupture. When the knee has been extended to a right angle and the leg is swollen, bluish, cold and pulseless, it is almost certain that vascular damage has occurred. After reduction of the dislocation, immediate exploration of the popliteal space is indicated. The artery may be in spasm, it may be damaged so that no blood is flowing through it or, more likely, it may be completely severed. Measures already enumerated in connection with injuries to the brachial artery are indicated except that an effort must be made in this situation to restore the continuity of the artery. If the popliteal artery has been ruptured, a huge amount of clotted blood will burst forth under pressure on exploration and bright-red blood will appear.

As just mentioned, a supreme effort should be made to restore the continuity of the artery under such conditions if this is technically feasible. An autogenous vein graft, a homologous arterial graft or possibly an Edwards-Tapp teflon prosthesis[8] may be used to bridge the gap. It is important to débride any damaged artery. This usually precludes bringing the ends together for direct suture.

If grafting is not possible and ligation of the divided ends of the artery is necessary, all the means available to promote collateral circulation should be used. The limb is placed in a modified Robert Jones protective dressing to which a posterior plaster slab has been applied. The limb is not elevated nor is heat applied. In general, results of arterial injury after dislocation of the knee have not been good so far as saving the extremity is concerned.

Fracture Through the Upper Third of the Tibia.—This fracture can jeopardize the arterial supply to the distal portion of the leg and the foot because of the proximity of the bifurcation of the popliteal artery. Amputation as a rule is necessary when an extremity has been fractured at or beyond the arterial injury. In such cases, however, the surgeon should make a supreme effort to restore the arterial continuity; if that is not possible, all means should be used to promote the collateral circulation to its highest state of efficiency. West and associates[9] reported a successful outcome in a case of fractured femur and disruption of the superficial femoral artery in which arterial continuity was restored by means of an autogenous vein graft.

To illustrate how closely allied peripheral vascular surgery is to orthopedics, I should like to mention the effect of a ridge in a cast in the popliteal region. In this instance, the cast apparently had been allowed to bend while it was being applied. The patient, who had sustained a simple fracture of the tibial shaft, complained of severe pain for two days. When the cast was removed, the leg was gangrenous and amputation above the knee was necessary. Examination of the specimen revealed pronounced venous thrombosis likely due to venous obstruction.

Direct Injury to Vessels.—The orthopedist may be confronted with an extremity that has been penetrated by a bullet, a knife or other sharp objects; wounds caused by miscellaneous sharp objects are increasing in this era of faster travel. The main artery may be completely divided, lacerated or contused, with resultant thrombosis, or put into a state of spasm.

Complete Severance.—As a first-aid measure,

direct pressure on the artery above the wound will control most of the bleeding when an artery is severed. Immediate exploration is indicated in such cases. When a large artery, such as the common femoral or popliteal, has been completely severed, consideration must be given to restoration of the continuity of the vessel. The divided ends of the artery occasionally may be brought together for direct suture. When this is not possible, a graft is necessary. This may take the form of an autogenous vein graft, for which the companion vein,

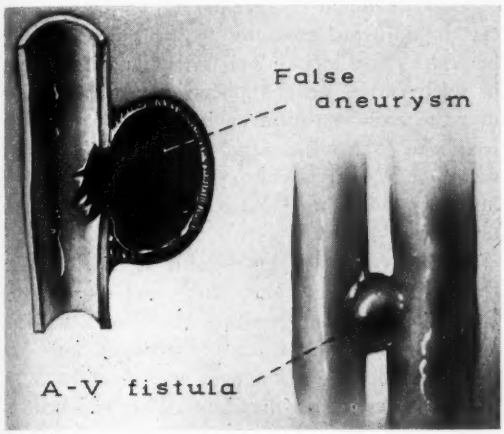

Fig. 2. False aneurysm and arteriovenous fistula.

the external jugular vein or a section of the saphenous vein may be used. In grafting the vein into the arterial system, the vessel should be reversed so that valves, if present, will not impede the flow of blood. A homologous arterial graft may be used. Currently, I am using a woven teflon prosthesis. In the case of smaller arteries, such as those below the elbow and the knee, ligation after complete severance usually may be done without impairing the distal arterial supply.

Laceration.—Arteries may be lacerated from a sharp object, such as a spicule of bone. If the condition is recognized early and repair of the laceration is carried out, the development of a false aneurysm or an arteriovenous fistula may be forestalled.

When the laceration involves a major artery, it is often possible to close the rent by lateral vascular suture with 00000 or 000000 silk on an atraumatic needle. Care must be taken not to constrict the lumen. It is often better to divide the artery completely and bring the ends together for end-to-end suture.

In laceration of smaller arteries, it is best to divide the vessel completely and ligate the ends rather than attempt to suture the rent.

Fig. 3. Arteriogram showing traumatic, or false, aneurysm.

If it is known that spurting bright-red blood or rapid expansion of a limb has occurred after a penetrating injury, it is best to explore. If this is not done, the surgeon may be confronted later with the problem of a delayed traumatic aneurysm or a traumatic arteriovenous fistula, depending on whether the artery or both the artery and vein have been perforated (Fig. 2).

Traumatic Aneurysm.—The clinical features of an aneurysm are globular pulsating swelling, distinct thrill and systolic murmur, congestion and edema of the distal parts, pain and disturbance of sensation, and erosion phenomena. Not all of these features may be present in every case.

Arterial aneurysms are more difficult to deal with than are arteriovenous fistulas because the collateral circulation does not develop as well in the former as in the latter. In the upper extremity,

extirpation of the aneurysm is usually a safe procedure.[10] If in doubt, the appropriate type of sympathectomy may be done. In the larger arteries

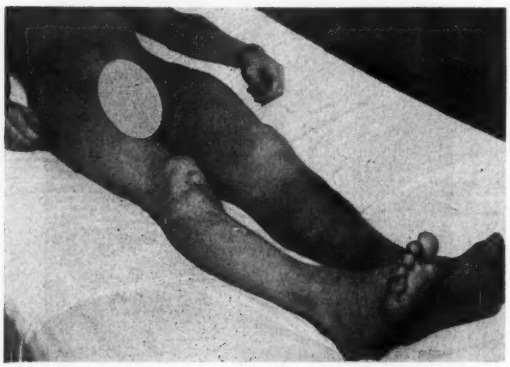

Fig. 4. A sixteen-year-old boy with a traumatic arteriovenous fistula of the left common femoral artery and vein.

of the lower extremity, extirpation and grafting may be necessary.

Figure 3 is an arteriogram of a traumatic, or false, aneurysm. In this case, the superficial femoral artery had been lacerated by a jackknife. The bleeding was controlled by pressure. Immediate exploration, with repair of the vessel, was not done. Later, pulsatile swelling developed indicative of a traumatic aneurysm, and a surgical procedure was then necessary to repair the vessel. The ultimate result was satisfactory.

Arteriovenous Fistulas.—Acquired arteriovenous fistulas seen in the past most often were caused by gunshot or stab wounds. With the increased incidence of serious automobile and airplane accidents, arteriovenous fistulas are being seen from these causes.

The local signs of an arteriovenous fistula are a pulsating lump, dilatation of veins, and a characteristic thrill and murmur. Arteriography is useful in arteriovenous fistulas in indicating the site of the communication.

Figure 4 shows a sixteen-year-old boy with an arteriovenous fistula following a gunshot wound two years previously. Note the enlargement of the involved extremity in both circumference and length.

Collateral circulation develops well in the presence of arteriovenous fistulas. This allows for treatment by the so-called quadruple ligation excision procedure.

It has been advised recently that the continuity of the artery be restored.[11] This procedure appears to be more applicable to recently acquired arteriovenous fistulas than to those of many years' duration. When the communication is a direct one, as in the case of a created arteriovenous fistula, the aperture in the artery may be repaired by a transvenous approach. The artery is repaired as one would repair an arterial laceration, and the vein is sacrificed.

Adjuvant Measures.—In addition to the direct surgical treatment of peripheral vascular injuries, certain adjuvant measures of treatment may be helpful. These include heparinization (if this can be safely carried out), application of a heat cradle over the abdomen, intravenous or intra-arterial injection of papaverine, administration of alcohol by mouth or by vein, use of oxygen, and wrapping the limb loosely in a modified Robert Jones protective dressing.

The ingredients of this dressing are as follows in the order of application: sheet wadding to hold the wound dressing in place, abundant absorbent cotton, eider-down or Kerlix bandages, and Ace bandages. The Ace bandages may be omitted. A posterior plaster slab may be applied and kept in place with a 10-cm. gauze bandage that has been soaked in water.

Occlusive Vascular Disease

As the average age of the population continues to increase, physicians will be confronted more and more with patients having symptoms due to occlusive vascular disease.

Arteriosclerosis Obliterans. Segmental Occlusion.—The clinical picture in segmental occlusion may vary considerably depending on the site of the early lesion and the degree of occlusion produced. Arteriography is helpful in determining the site of the occlusion. Blockage of the distal part of the aorta or great iliac arteries may give rise to pain in the back or to claudication about the hip.

Orthopedists often are asked to see patients who are considered to have a protruded intervertebral disk in the lower part of the lumbar region. After a history has been taken carefully and examination and aortography have been done, such a patient may be found to have occlusion of the terminal portion of the aorta or of one of the great arteries within the pelvis.

Occlusion of the femoral artery may cause claudication in the thigh, but more often the pain occurs in the calf of the leg.

Time does not permit discussion of the various surgical procedures that may be done in segmental arterial occlusion. When the involvement is above the inguinal ligament as well as below, it is desirable to co-operate with a general surgeon who is interested in vascular surgery.

In the management of segmental occlusion of the superficial femoral artery, it is our practice at present to bypass[12] the occluded segment with either a homologous arterial graft or a woven teflon prosthesis. There must be a good "run-in" of blood as well as a good "runoff" before the bypass operation is considered (Fig. 5).†

Rob[13] has stated that arterial reconstruction is the treatment of choice for patients who have pain at rest and gangrene, because the alternative is usually a major operation. In his experience, such a procedure is possible in about 20 per cent of patients with gangrene of the toes and feet. He pointed out that a patient with gangrene and clinical evidence of aortoiliac and femoropopliteal thrombosis should have an arteriogram to see if the limb might be saved.

Diffuse Involvement.—When diffuse involvement is present in arteriosclerosis obliterans and intolerable ischemia exists, the surgical treatment is amputation. In such an event, it is desirable that amputation be done so that the stump is below the knee. Our practice in most instances is to begin at the site of election below the knee. If brisk bleeding does not occur and the muscle is pale and bloodless, amputation above the knee is carried out. We have had poor success with amputation of the toes in arteriosclerosis obliterans and not much better success with the transmetatarsal procedure in this disease.

Peripheral Arteriosclerotic Aneurysms.—These lesions should be dealt with before complications appear. The complications include thrombosis, embolism, gangrene, pressure on veins and nerves, and rupture. Treatment of such an aneurysm of the common femoral artery is difficult. It may be accomplished on occasions by extirpation or obliteration of the aneurysm, with restoration of the arterial flow by the bypass technique. When the arteriosclerotic aneurysm occurs elsewhere than in the region just mentioned, it has been our practice[14] to do the appropriate sympathectomy or alcohol sympathetic block and extirpation of the aneurysm at the same operative session. In a few cases of arteriosclerotic popliteal aneurysm, we have bypassed the aneurysm and either extirpated it or obliterated it.

Thromboangiitis Obliterans. — This condition usually occurs in younger persons than does arteriosclerosis obliterans. Direct surgical attack on the vessels in thromboangiitis obliterans as a rule is confined to biopsy of an easily accessible artery to establish a diagnosis. Such a specimen most often is taken from the distal portion of an occluded ulnar artery. Major surgical treatment in thromboangiitis obliterans usually is limited to sympathectomy. Whereas conservatism in amputation in the presence of arteriosclerosis obliterans is not advised, quite the reverse is true in thromboangiitis obliterans. Amputation of all or a part of one or more digits often will succeed in thromboangiitis obliterans, even though at times the healing will be slow.

Arterial Embolism.—This is the most dramatic form of arterial occlusion. The common origins of the embolus are (1) left auricular clots that form during fibrillation, (2) ventricular mural thrombi present over a myocardial infarct and (3) aortic mural thrombi forming over ulcerated atherosclerotic plaques. The clinical features of peripheral arterial embolism are pain, blanching, tingling, cold, anesthesia, loss of power and loss of pulsation.

Early vigorous medical treatment may prove successful. If, however, signs of returning circulation are not evident in two or three hours, it is probable that embolectomy should be done. The common site of lodgment of the embolus is at one of the major bifurcations.

Embolectomy in most cases can be done with the patient under local anesthesia. The incision should be adequate and should be made over the line of the artery. Bony parts, such as the clavicle or upper part of the fibula, can be removed to gain good exposure, as advised by Elkin and Cooper.[15] The incision is developed so that an adequate segment of normal artery is present above and below the site of obstruction. Cotton tapes or arterial clamps are placed around the artery above and below the intended site of arteriotomy to control the flow of blood and to prevent distal embolization.

A word of caution is in order in concluding this

†See page 105.

discussion of occlusive vascular disease. Patients suffering from this condition are not good candidates for elective orthopedic procedures on the extremities.

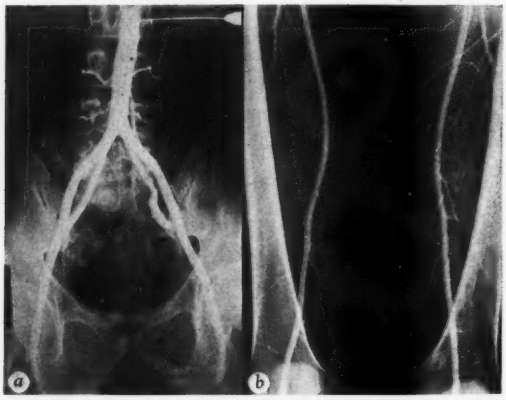

Fig. 6. *(a)* Aortogram showing normal pelvic arteries. *(b)* Aortogram showing normal thigh arteries.

Arteriography

The first arteriogram on a living person was carried out in 1923.[16] It has been said that about 85 per cent of the affections of the peripheral arteries can be diagnosed correctly after a good history has been taken and physical examination has been done. According to Learmonth,[17] the purpose of outlining the peripheral arterial tree by an opaque medium includes the demonstration of (1) its anatomic arrangement, whether normal or abnormal, (2) the presence of local irregularities in caliber in arteriosclerosis or thromboangiitis obliterans, (3) thrombotic blockage of main trunks in obliterative vascular disease, (4) the extent of the collateral circulation, (5) the site and extent of arterial aneurysms and (6) the site of arteriovenous fistulas.

Two methods of injecting radiopaque material into the artery may be used: (1) the needle is inserted through the skin and underlying tissues into the artery (closed method) or (2) an incision is made down to the artery and the needle is inserted under direct vision (open method).

The open method has three definite advantages, namely (1) the artery is entered readily with the needle without undue trauma, (2) the chance of extravascular injection of the radiopaque substance is minimized and (3) a cotton tape may be placed proximally to the point of arterial puncture so that the arterial flow may be occluded at the moment of injection. This allows for a heavy concentration of radiopaque material and thus a better arteriogram.

Although my associates and I use both the open and closed methods, the description of the technique will be limited to the open method. The procedure is carried out in the operating room. A test dose of a 35 per cent solution of iodopyracet (diodrast) is injected intradermally on the volar aspect of one of the patient's forearms. If a cutaneous reaction has not occurred at the end of fifteen minutes, arteriography is carried out.

When arteriography is to be done on one or both of the lower extremities, it is often convenient to use a fracture table, which facilitates quick handling of the cassettes. However, the usual operating table or a regular x-ray table may be used.

The extremity on which the arteriogram is to be made is slightly rotated externally. When the fracture table is used, two x-ray machines are placed so as to take roentgenograms in two planes or two slightly oblique views at different levels of the extremity.

The patient is anesthetized by the intravenous injection of a solution of thiopental (pentothal) sodium. A dose of 1 ml. (20 mg.) of succinyl choline may be given just prior to the injection of the radiopaque material to prevent any motion of the extremity while the arteriogram is being made.

An incision 7.5 to 10 cm. in length is made over the common femoral artery. The artery is carefully isolated and a cotton tape that has been soaked in an isotonic solution of sodium chloride is then placed around it. Approximately 50 ml. of a 35 per cent solution of diodrast is drawn up into a 50-ml. syringe fitted with 25 cm. of rubber tubing to which a 15 or 17-gauge needle is attached. The tubing allows for various motions of the syringe without disturbing the needle within the artery. While an assistant obstructs the arterial flow by gentle traction on the tape, 40 ml. of diodrast is injected and a roentgenogram is made while the remaining 10 ml. of the medium is being injected. Various modifications as to timing and projections are necessary according to the condition that is clinically suspected to be present. Close co-operation with the x-ray technician is imperative. After the needle has been withdrawn, a pledget of gelfoam is held over the opening in the artery until there is no further bleeding.

When the digital arteries of the hand or vessels

of the forearm are to be visualized, the extremity may be kept flat on the cassette by placing a used x-ray film over the hand and pressing each side of this film down to the table with sandbags, one on each side of the hand.

A 7.5-cm. incision is made over the middle portion of the brachial artery with the patient under pentothal anesthesia. Care is taken not to injure the median nerve. The rest of the procedure is essentially the same as has been outlined for arteriography in the lower extremity.

The roentgenologic technique that we have employed is as follows: for the hand and forearm, 20 milliamperes, 80 kilovolts, a distance of 80 cm. (32 inches) and an exposure of 1/20 second; for the lower extremity, 20 milliamperes, 90 kilovolts, a distance of 80 cm. (32 inches) and an exposure of 1/10 to 3/20 second. Examples of arteriograms are shown in Figures 6, 7 and 8.

Fig. 7. *(a)* Arteriogram showing normal popliteal artery pushed posteriorly by a soft-tissue mass. *(b)* Arteriogram showing occlusion of the lower femoral artery due to injury by bird shot. *(c)* Arteriogram of arteriosclerotic popliteal aneurysm.

Persons doing arteriography should have some regard for exposure to roentgen rays. A lead apron should be worn, and sufficient rubber tubing should be used on the syringe so that the hands of the person making the injection may be kept as far out of the field as possible. A lead shield may be placed between the surgeon and the patient.

Problem of Leg Length

An experimental aspect of the relationship between peripheral vascular surgery and orthopedics is the creation of an arteriovenous fistula for the purpose of stimulating the longitudinal growth of bone.

The problem of the short leg in a child, from whatever cause, always has been challenging to orthopedists. It has been observed that patients who have a congenital arteriovenous communication or communications often have a longer extremity on the affected side. Likewise, I have observed longer extremities in patients who have arteriovenous fistulas acquired before epiphyseal closure. Thus, it was considered reasonable to attempt to increase leg length in puppies by creating an arteriovenous fistula between the major vessels of one of the hind legs. Work was begun on this problem in 1947.[18] That this is not an original idea was brought to my attention by Dr. J. R. Moore, who told me that Dr. R. B. Osgood, in 1929, after examining a child with an elongated extremity due to an arteriovenous fistula, mentioned the possibility of harnessing this abnormal vascular correlation to stimulate the growth of bone.

Fig. 8. *(a)* Arteriogram in a case of thromboangiitis obliterans. *(b)* Arteriogram in a case of fibrosarcoma.

Arteriovenous fistulas about 1.25 cm. in length were made between the left external iliac artery and vein in ten puppies. In nine of ten animals, the left femur (side of the fistula) was longer than the right at necropsy. In six of ten animals, the left tibia was longer than the right one. The weights of the left femora and tibiae compared with those of the right femora and tibiae roughly paralleled the differences in size. In four animals in which the difference in temperature in the

medullary cavities of the left and right femora was recorded, the left one was warmer in each instance.

After some delay and with considerable trepidation, my colleagues and I considered applying the procedure to a child with a short lower extremity. Among reasons for the delay were the observations that the increase in the leg lengths of these puppies was not great and that in one case the left hind leg turned out to be shorter than the right, and the fact that we were not sure of the effect on the heart.

The first fistula in such a patient was created at the clinic in 1950, after the parents of the child were fully briefed on the subject. They understood that two operations would be involved, one to make the fistula and a second one later to repair it. They were also made aware of the possible complications.

To date, we have created forty-five such arteriovenous fistulas, ten of which have been repaired. Dr. Howard Burchell, one of the cardiologists at the clinic, has carefully followed these patients. Cardiac complications have not appeared to date. No restriction has been placed on the activities of the children who have undergone the procedure. None of the local complications described in connection with arteriovenous fistulas have been observed, with the exception of mild to moderate venous stasis. In cases of short leg due to anterior poliomyelitis, this stasis has not been unwelcome to the parents or the child, as it has caused filling out of the atrophied limb so that it approaches the other in appearance. It is not intended to allow the fistula to operate for a long enough period to produce unwanted changes resulting from venous stasis.

We are not in a position to give a final report on this series of patients, as many are still in the actively growing period. Stimulation of the growth of the short extremity has varied all the way from zero to a 4-cm. "catch up" over a four-year period. It has become apparent that the creation of fistulas in patients more than twelve years of age is not indicated except when the procedure is accompanied by stapling, or epiphysiodesis, of the normal extremity. The youngest patient in our series was four years of age. The parents or the patients uniformly have noted that the thigh and upper half of the leg on the side of the fistula are warmer than they were before operation.

Several problems with regard to this work remain unanswered: 1. How much stimulation of growth can be expected? 2. When should the fistula be induced? 3. How long should it be left in operation? 4. Will stunting of growth occur in some patients, as was noted in one of the dogs? This method of attempted equalization of leg length is still in the experimental phase, and this must be realized by the parents who submit their children to it as well as by the surgeon who carries it out. We hope to have more data on this work as time goes on. The procedure is not recommended for a shortened upper extremity.

A Community Medical Assistance Plan

● *Medical practice in small towns does not appeal to many eager young graduates of modern medical schools. As a result, many communities are left without physicians as the older generation of practitioners dies. The Sears-Roebuck Foundation has developed plans to aid such communities to establish their needs and obtain physicians on a self-help basis.*

J. ARNOLD BARGEN, M.D.

From the Section of Medicine, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

THE popular picture of rural practice is that of the elderly physician with his little black bag—a man and his community with mutual confidence. Some of us can remember that far back, while others probably have conceived it from watching television "Westerns."

This picture is different from the concept our interns and general-practice residents have of medical practice today. For them the small-town practice is far from attractive, which is why they flock to the already overcrowded cities to start their practice, to the detriment of rural medicine. This is why hundreds of our smaller towns, once adequately taken care of by local physicians, now

find themselves dependent medically on the nearest city. This means driving several miles to see the doctor, and because of the distance frequently the trip is not made when it should have been. Emergency medical care is practically nonexistent.

The Medical Advisory Board of the Sears-Roebuck Foundation (a board of thirteen physicians appointed by the American Medical Association) asked the Foundation to study the problem and if possible to assist in solving it.

The Foundation first checked the experience of young physicians who fairly recently have started their practice in a small town, to find out why they decided on the small town, and what has been their success since they started.

First, they found most of these were originally from small towns or rural areas. They liked the small-town way of life.

Second, some of these physicians were not too successful. A few were even thinking of moving elsewhere. In practically every such case, the physician had quietly moved into town, taken over the office space of the former physician and hung out his shingle. Although the space had satisfied the former physician for twenty to thirty years, it was not a facility where modern medicine could be practiced adequately. It compared ruefully with the facilities occupied by city physicians. During the time since the former physician died and the new one arrived the people in the area had made contacts with the city physicians, and mainly because of the better facilities they continued going to the city for their general ills. Of course they would employ the services of the local physician for emergencies and house calls, but a physician cannot live on that alone.

Now, how does one overcome the medical habits of a community? The Sears-Roebuck Foundation feels that it has the answer. It is the building of a modern medical center. Modern medicine requires modern diagnostic facilities. The day of practicing from the "little black bag" or using space up above the bank or converting a store building simply will not enable a physician to practice the way he was trained. Obviously the physician using such facilities in a rural area will not inspire confidence nor can he compete with the better facilities available in the city.

The Foundation selected one of the outstanding medical architects in the country to develop a functional, inexpensive, modern medical center (Figs. 1-3). It contains features not found in any other medical center in the country. The circular patient-flow pattern provides for better patient comfort, enables maximal efficiency of the physician's time, and provides for central control enabling one person to handle the duties of nurse, receptionist and laboratory technician.

Another feature of maximal importance to a physician is that all "group I" equipment such as instrument cases, filing cases, bookcases, storage areas, and lavatories are all built in and serve as nonweight-supporting wall sections. This "built-in" feature is found only in the Foundation plan.

But how does this guarantee that the people use the services of the physician? First, the facility is modern in every respect and is better than, or at least equal to, any they will find in neighboring towns. But the big reason is that the people—the entire community, not just two or three wealthy leaders—have invested in this building. They intend to pay interest on any indebtedness on the building. How can they pay interest, let alone recover their investment, unless they use the physician and the modern facility?

Only those communities that can support a physician should be encouraged to build modern medical facilities.

The Foundation has developed a way to determine a community's medical habits and ability to support a physician. This is done by means of a person-to-person survey. The Foundation developed the questionnaire, a local organization such as the Lion's Club, Kiwanis Club, Rotary Club or the Chamber of Commerce does the actual contact work, and then the forms are sent to the home office of the Foundation for statistical processing.

The survey findings work two ways. They tell the physician the medical need in the area and the townspeople the economic loss they are sustaining each year they are without a physician.

To the prospective physician they can give such information as:

1. The number of illnesses in the area during the last twelve months.

2. How many of these needed physician care; how many office calls; where did the patients go; how far did they have to travel; and approximately how much did they pay for professional care.

3. How many were hospitalized; in what hospital; how far away and for what.

4. What per cent of the population carries hospital insurance, health insurance.

5. Approximately how much income could the physician expect the first year.

The Foundation is now ready to present these facts to the community. This is done at a town meeting. A representative from the Foundation explains the findings of the survey. He presents

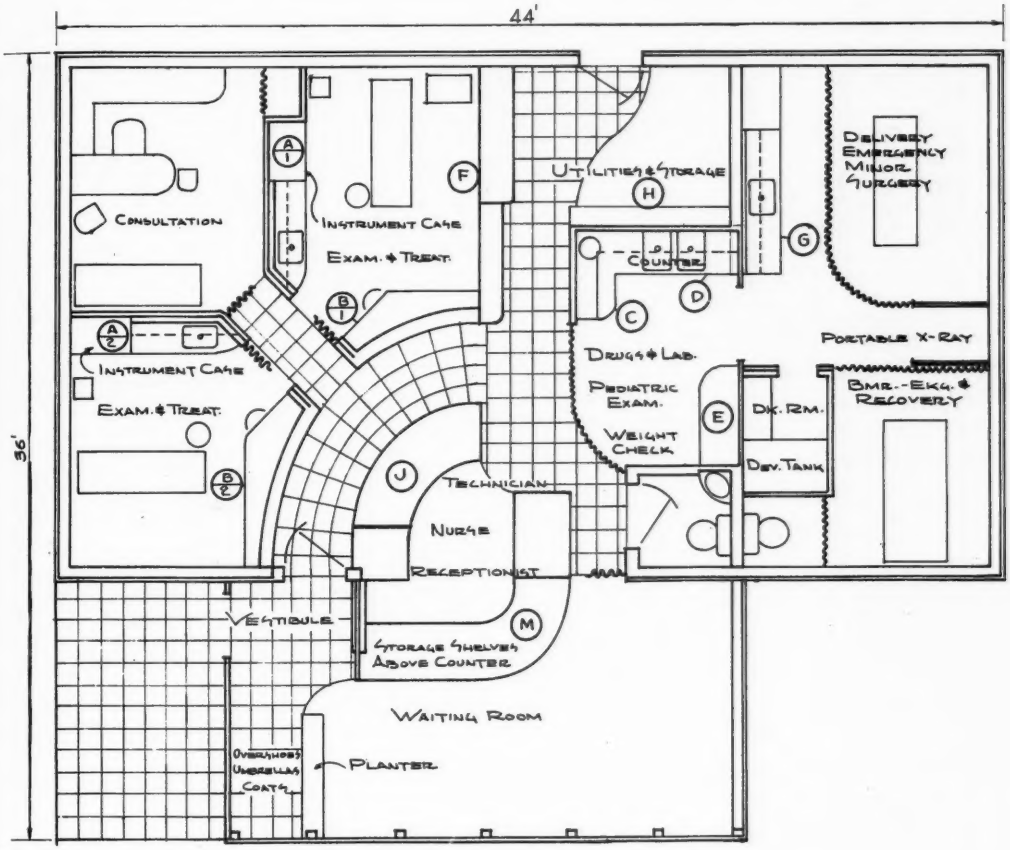

Fig. 2. One-physician plan.

To the community it gives, for example, in Hull, Iowa—a trade area of approximately 5,000 population—the following information:

1. The people of this area are averaging a collective 966 miles per day just going to and returning from their physicians in the surrounding cities.

2. These people are spending at least $33,216 in physicians' office calls alone, $26,500 for medicines purchased in these other towns, and $3,800 for gas and oil alone in going to the physician, making a total annual sum of $63,516.

3. These people also purchase, at the time of visiting the physicians, items that could just as well be purchased in Hull, Iowa; this is estimated to be more than $44,000 additional.

the plans of the building the Foundation has developed and explains that the Foundation will furnish free of charge all necessary plans and working specifications. The community must raise the money and build the facility. The Foundation will also help them in planning their campaign for fund raising, and help them organize a trusteeship or nonprofit corporation to own the building, manage it, and rent it to the physician; the state medical society and the placement agency of the American Medical Association will assist the community in getting the physician; and after the physician arrives the Foundation will send an expert on the business side of medicine to help him get started right.

A vote to go ahead starts the ball rolling.

The most surprising thing in the whole program is the short time it usually takes the community to raise the money. One community found it so easy that as soon as the money for the "Medical Center" was raised they started another drive to raise $40,000 for a community-center building.

The unique thing about the plan is that the Foundation gives only "know-how" and no money. The basic principle guiding the Foundation in this as in other programs is: "Help others to help themselves." The Community Medical Assistance Program is just one of many, but is the only project in the medical field.

This program is fairly new, having been started last February. By November it had twenty-two communities across the country co-operating. Some of these have their building finished and the physician practicing, while others are in either the building or the fund-raising stage. The major limitation is the availability of physicians. As the program becomes better known, even this problem should be solved.

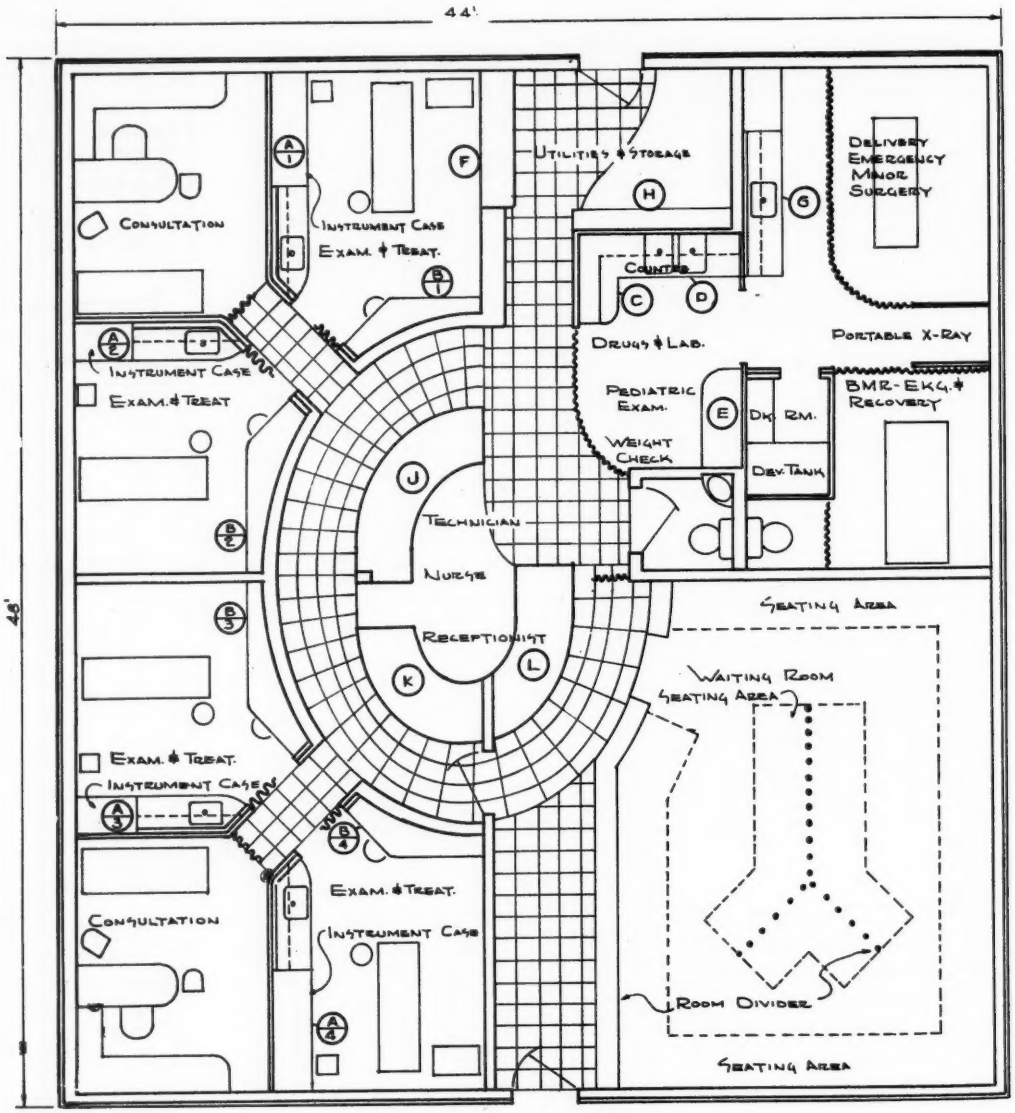

Fig. 3. Two-physician plan.

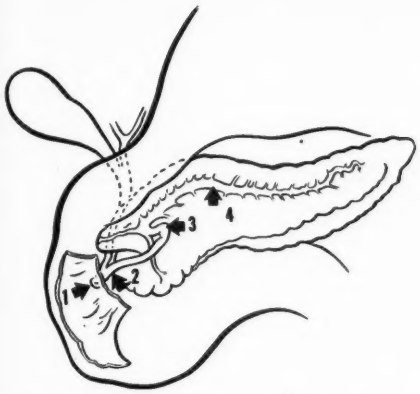

Fig. 1. The sites of pancreatic duct obstruction in chronic pancreatitis.

Surgery of the Pancreatic Ducts

ALAN P. THAL, M.D., Ph.D.
Minneapolis, Minnesota

SINCE the first cannulation of the pancreatic duct by Reynier de Graaf in 1662 surgeons have been dilatory in their approach to this gland. The catastrophic sequelae of meddlesome surgery in this area cannot fail to impress. Over the past twenty years surgical techniques have advanced considerably and major procedures are now commonly undertaken on the pancreas with a low mortality rate. The present communication deals with direct surgical approaches now being utilized in the treatment of chronic pancreatitis.

Necropsy and operative studies have shown that chronic pancreatitis is often the result of pancreatic duct obstruction.[1] The promising results which have followed successful decompression of the pancreatic ducts tend to support this finding.

The Sites of Pancreatic Duct Obstruction.—The etiology of noncalculous obstruction to the pancreatic duct is far from clear. Periductal fibrosis, squamous metaplasia and obstruction by inspissated secretions appear to be important.

The site of the obstruction may vary considerably as shown in Figure 1. Obstruction at the duodenal level may be due to papillary spasm or fibrosis. It is now also apparent that the pancreatic duct orifice may participate separately in this narrowing process. In such cases section of the common ampullary sphincter, alone, does not provide drainage of the pancreatic duct. In treating chronic pancreatitis surgically it is often necessary to enlarge the pancreatic duct orifice separately.

In the more advanced case of chronic pancreatitis the common site of stricture is in the head or body area of the gland. In the advanced case, obstruction may be multiple and even involve microscopic ductules making operation on the main pancreatic ducts futile.

Examination of the Pancreas at Operation.—Superficial palpation of the pancreas is unrewarding and often results in error. This is in part due to fat accumulation in and around the abnormally inflamed pancreas masking the underlying disease. The head of the gland can only be carefully examined after division of the lateral ligament of the duodenum and mobilization of the transverse mesocolon. The body is best inspected through an incision in the anterior wall of gastro-hepatic omentum and the tail is best approached through the gastro-colic omentum.

From the Department of Surgery, University of Minnesota, Minneapolis, Minnesota.
Inaugural thesis presented before the Minneapolis Surgical Society, March 6, 1958.

Localization of the Site of Duct Obstruction.—The approach to the origin of Wirsung's duct is made through the ampulla of Vater. When there are no indications for common duct exploration the papilla of Vater is identified after cholecystectomy by passing a ureteral catheter through the cystic duct into the duodenum. A 2 cm. longitudinal incision is made in the duodenum over the papilla and by means of stay sutures the papilla is extruded through the duodenotomy. Sphincterotomy is then performed simply to expose the pancreatic duct orifice. Figure 2 demonstrates the various positions of this orifice. It should be emphasized that cholecystectomy should always accompany sphincterotomy to prevent the development of chronic cholecystitis.

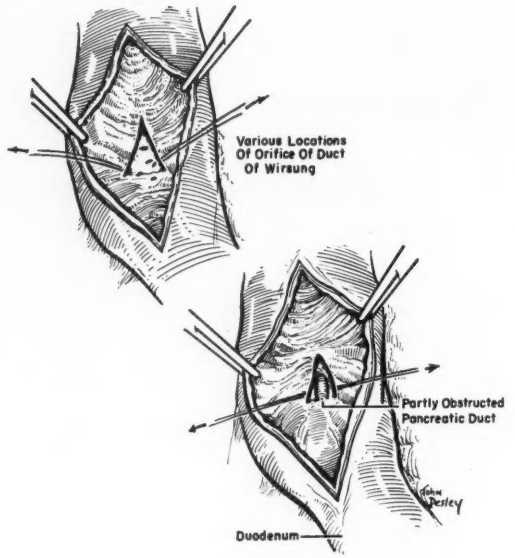

Fig. 2. Various locations of the main pancreatic duct orifice as seen at spincterotomy. In the lower illustration the pancreatic duct, obstructed at its orifice is seen bulging through the posterior wall of the ampulla.

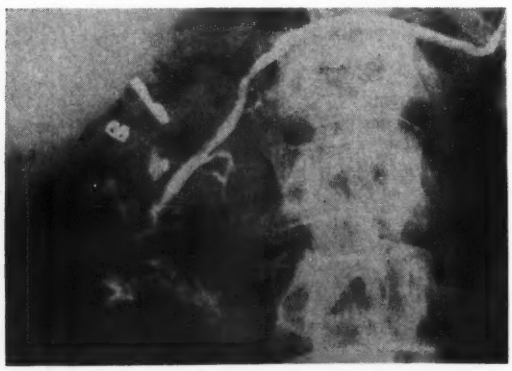

Fig. 4. Pancreatogram of a slightly dilated pancreatic duct. In this case the obstruction was brought about by fibrosis of the pancreatic duct orifice in the ampulla. This patient responded nicely to separate sphincterotomy of the pancreatic duct.

Where the pancreatic duct is chronically obstructed in the head of the gland the dilated duct assumes a superficial position on the anterior surface of the body of the pancreas behind the antrum of the stomach and may be palpated readily (Fig. 3).

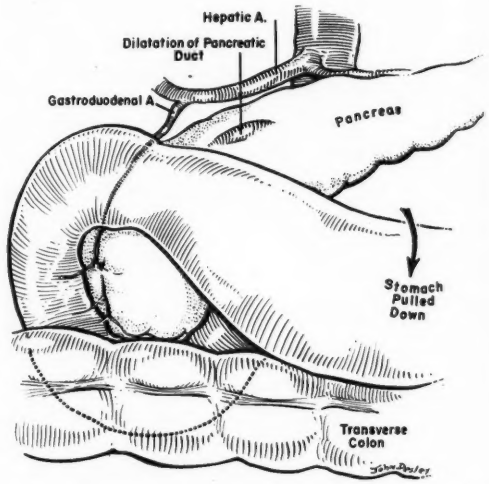

Fig. 3. The anatomic position at which the chronically obstructed pancreatic duct becomes palpable.

For retrograde decompression the duct may be identified easily after distal pancreatectomy.

Pancreatography.—This technique may be extremely useful in localizing the site of obstruction. Initial cholangiogram may reveal obstruction at the papilla. Direct pancreatography is indicated when gentle probing of the pancreatic duct reveals an obstruction. A fine polyethylene ureteral catheter (#3 or #4 French) is gently introduced into the pancreatic duct. Where obstruction is incomplete the catheter will often traverse the main duct throughout its length. Renografin 38 per cent is then allowed to gravitate through the tube. The small size of the catheter allows reflux back into the duodenum and prevents undue pressure elevation. X-ray will demonstrate the dilated distal pancreatic duct. With increasing experience in this

area pancreatography may be dispensed with in the majority of cases. The catheter may also be of value in sampling pancreatic juice beyond the site of obstruction. Juice taken from an obstructed duct is often frankly purulent.

The Operative Approach to the Problem of Pancreatic Duct Obstruction.—The type of procedure performed will of necessity depend on the site of obstruction.

1. Obstruction at the ampulla of Vater. The

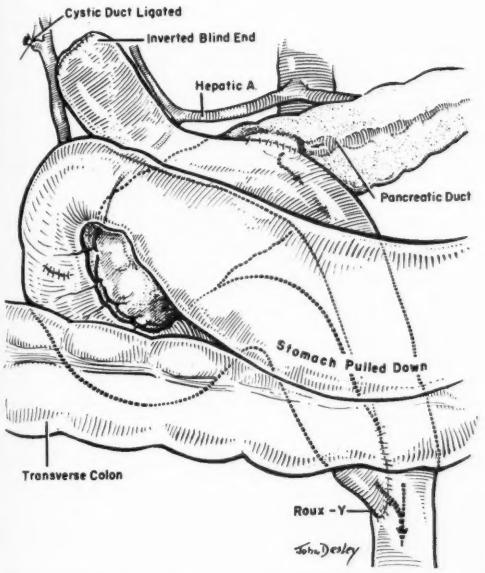

Fig. 5. Side-to-side pancreato-jejunostomy. There is no sacrifice of pancreatic tissue in this procedure.

pancreatic and bile ducts may be separately or commonly involved by spasm or fibrosis at the papillary level. In the former instance the pancreatic duct sphincter must be separately divided after papillotomy. In the absence of intrapancreatic obstruction a soft metal probe will traverse Wirsung's duct into the tail of the gland with ease. It is mandatory that the pancreatic duct orifice be located when sphincterotomy is performed for drainage of the pancreas.

A small calculus may be removed through this approach using otologic alligator forceps.

2. Stricture in the head or body of the pancreas. After an obstruction has been demonstrated at a distance from the duodenum the duodenotomy is closed and cystic duct ligated. With longstanding obstruction the dilated main pancreatic duct comes to lie quite superficially on the anterosuperior surface of the gland behind the antrum of the stomach. If this duct can be palpated readily we favor a side-to-side anastomosis of the dilated duct to a

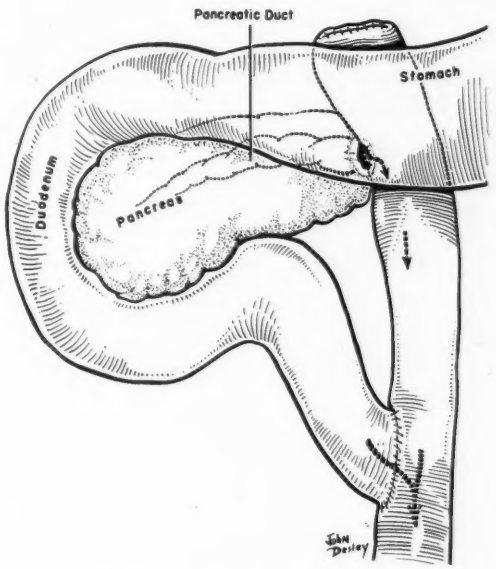

Fig. 6. Caudal pancreatectomy with pancreato-jejunostomy. The tail of the pancreas is resected to give access to the dilated duct.

Roux-Y loop of jejunum as illustrated in Figure 5. The advantage of this operation is that pancreatic islet tissue is preserved and a wide anastomosis can be made. When a dilated duct cannot be readily palpated we prefer distal pancreatectomy and Roux-Y drainage (Fig. 6) an operation originally proposed by Robert Coffey in 1909.[2]

3. Diffuse inflammatory disease of the head of the pancreas. In these cases there are often multiple strictures and many calculi in the head of the gland. Here the procedure of choice is partial pancreato-duodenectomy. The operation can now be performed with a low mortality rate and the results are excellent particularly when the islet and acinar tissue of the tail is not completely destroyed.

Techniques of Pancreatic Duct Anastomosis.—The cut surface of the pancreas should be handled with as much care as an opening in the bowel. All bleeders and ductules are carefully grasped with mosquito forceps and tied with fine silk. The main duct is then isolated and the cut surface of the

pancreas is then carefully inverted around the pancreatic duct. In general no tube is necessary for duct anastomosis which is made with interrupted arterial silk. A buttressing row of 5-0 silk is laid posteriorly and anteriorly to approximate the inverted surface of the pancreas to the serosa of the bowel. It is an experimentally proven fact that these anastomoses remain patent only when other avenues of drainage are partially or completely obstructed.[3]

TABLE I.
CHRONIC PANCREATITIS TREATED SURGICALLY
(36 Cases)

	Number	Good Results	Poor Results	Operative Mortality
Sphincterotomies	29	24	5	2 (7%)
Pancreato-duodenectomy	2	2		0
Retrograde drainage	4	4		0
Marsupialisation of pseudocyst	1	1		0
Negative exploration	2			0

Explorations revealing disease other than pancreatitis:
1 carcinoma third portion duodenum.
1 carcinoma head of pancreas.

Results of Surgical Treatment of Chronic Pancreatitis.—The results of the last thirty-six operations for chronic pancreatitis are summarized in Table I. From this table it will be seen that the majority of cases were approached by the ampullary route.[4] The remaining cases represented examples of more advanced disease where the obstruction lay in the head or body of the gland. Diagnosis is often a problem, and four cases, listed in this table, were misdiagnosed as chronic pancreatitis. Exploration in two of these cases revealed unsuspected neoplasms.

The results of decompressive surgery in chronic pancreatitis must be measured in several parameters. Early in the course of the disease therapy is aimed at the prevention of recurrent attacks of acute pancreatitis. At this stage the obstruction is often localized to the duodenal area and can be treated easily by sphincterotomy. In the majority of cases successful decompression prevents recurrence.

Late in the disease, therapy is aimed largely at treating pain, exocrine insufficiency and in preventing or retarding the development of diabetes. Where the duct can be adequately decompressed the results are most gratifying. In some cases of advanced disease the pancreas is a fibrocalcific mass containing multiple isolated abscess and decompressive operations are without value. Early treatment is important in this disease and decompression of an obstructed duct protects both acinar and islet tissue. Nevertheless, even in advanced disease, partial return of exocrine activity may follow a drainage procedure.

Discussion

When obstruction due to stone or stricture occurs within the head of the pancreas, the pancreatic juice in the obstructed duct is frequently grossly purulent and yields coliforms, streptococci or staphylococci on culture. Repeated bouts of pancreatitis are of grave portent both in regard to exocrine and endocrine function. Indeed, the latter deficit as shown by an abnormal glucose tolerance test, may long precede any demonstrable exocrine deficiency. Surprisingly, far-advanced chronic pancreatitis may exist in patients showing little or no digestive defect. Steatorrhea is a very late sign of advanced disease. When clear-cut ductal obstruction is relieved there is good evidence of regeneration of acinar tissue even after long-standing obstruction.

Decompressive surgery of the pancreatic ducts has great merit in the treatment of chronic pancreatitis and should certainly be preferred over indirect procedures such as sympathectomy, partial gastrectomy or transplantation of the bile duct. Precise identification of the point of obstruction and careful technique are the most important factors influencing a successful outcome.

As a group, the chronic pancreatitis patients are difficult to manage. Often they are discouraged by the results of previous surgery, many are addicted to opiates or alcohol, some have frank diabetes, anemia or malnutrition. They are pain-racked and depressed. These problems only serve to heighten the dramatic effect of successful surgery.

LARGE GASTRIC LESIONS

TWO CASE REPORTS

PHILIP W. BROWN, M.D.
Rochester, Minnesota

Gastric cancer and gastric ulcer continually present critical differential problems in diagnosis. It has long been realized that as the size of a gastric lesion increases, the percentage of benignancy decreases. In a study of 759 cases of gastric ulcer Comfort and associates[1] found that only 2 per cent of the ulcers had a diameter of more than 7 cm. By contrast, in a group of 924 cases of gastric cancer, 42 per cent of the lesions were 7 cm. or greater in diameter. This figure of only 42 per cent of lesions more than 7 cm. in diameter presents an interesting angle concerning gastric lesions, in that it reflects the attitude of the Mayo Clinic staff of considering these lesions as surgical problems. In our opinion a gastric lesion is guilty until proved innocent, granting the exceptions that apply to any such categorical statement.

From the Section of Medicine, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is part of the Graduate School of the University of Minnesota.

Read at the meeting of the Minnesota Society of Internal Medicine, Duluth, Minnesota, October 20, 1958.

Certainly all physicians agree that the earlier a gastric cancer is diagnosed and the patient is operated on, the better the chance of cure. However, a corollary of this commendable attitude is the occasional pronouncement that a large gastric lesion is malignant, when such is not so. So many hopeless situations are encountered among patients having gastric lesions that the salvaging of any patient is a source of much rejoicing for the patient and satisfaction for his physician. Two remarkable cases have recently come to my attention and are presented briefly forthwith.

Report of Cases

Case 1.—A man, aged sixty-three, came to the Mayo Clinic on March 6, 1958. In November, 1957, he had begun to have severe sharp pain in the epigastrium. This pain would occur three or four days per week and came on several times a day, usually thirty to sixty minutes after meals, and might last as long as thirty minutes. The patient had thought that the pain was worse if he ate meat and so-called heavy foods. Vomiting afforded relief, and he had begun to induce it. Likewise, a bowel movement seemed to relieve the pain. Milk and alkalies

Fig. 1. Case 1.

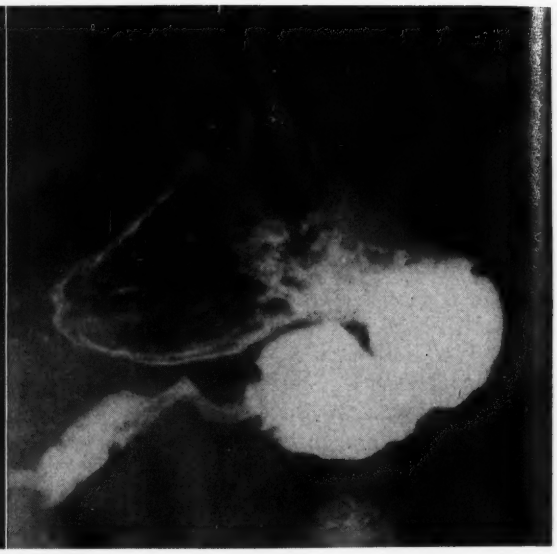

Fig. 2. Case 2.

did not afford relief. The pain radiated to the lower portion of the abdomen and also through to the back; this latter pain had awakened him at night.

He further stated that he had undergone operation on December 4, 1957, because preceding x-ray studies of the stomach had revealed definite pyloric obstruction. At operation the surgeon reported finding a large carcinoma of the pylorus with a mass which was so large and extensive that resection was not feasible. A third of the stomach was involved with a lesion which had eroded through the serosa and had extended posteriorly and involved the retroperitoneal lymph nodes. Hence, the abdomen was closed after exploration. No tissue was removed for histologic study.

After operation the patient's condition remained static. The epigastric distress persisted. His appetite was poor, and yet he did not have as much discomfort as might be expected in three months' time. Some members of his family urged that further opinion be obtained; others felt the situation was hopeless.

On the patient's arrival at the clinic, about three months after operation, his weight was 107 pounds compared to 145 pounds the previous fall. He was pale, weak and emaciated. An indefinite fullness could be felt in the upper part of the abdomen, but there was no definite hard mass or any enlargement of the liver. The pertinent laboratory studies disclosed a hemoglobin of 11.6 gm.; erythrocytes numbered 4,900,000 and leukocytes 12,700 per cubic millimeter of blood. The sedimentation rate of the erythrocytes was 44 mm. for the hour. The result of the bromsulphalein dye-retention test was zero. X-ray studies of the thorax did not show evidence of any abnormality. X-ray studies of the stomach were reported to show evidence of a large ulcerating carcinoma involving the lower half of the stomach (Fig. 1).

The patient was determined to have further operation if the surgeon was willing. This was agreed upon. Operation disclosed the presence of a large ulcerating lesion on the lesser curvature and posterior wall of the stomach just above the pylorus. This lesion had penetrated through and into the left lobe of the liver, superiorly and posteriorly, as well as into the body of the pancreas. No nodules were felt in the liver. Numerous specimens for biopsy were taken from various sites, but malignant cells were not found. Therefore, subtotal gastric resection was carried out with removal of the lower two thirds of the stomach and wide excision around the ulcerating lesion. The anastomosis was accomplished as an anterior Hofmeister-Polya modification. The patient's postoperative course was satisfactory. During the operation he received two pints of blood; the usual fluids and electrolytes were given until oral feedings were begun. The temperature did not rise above 100° F. or the pulse above 90. Drainage from the wound had practically ceased when he left for home.

The patient was dismissed from the hospital on the tenth postoperative day, and he left for his home ten days later. The pathologic study of the resected specimen confirmed the benign lesion, which was primarily an ulcer which measured 8.5 cm. in diameter. The lesion was located on the posterior wall and lesser curvature of the stomach. The ulcer base involved the pancreas and the liver. Several lymph nodes showed inflammatory reaction. This reaffirmed the absence of any carcinoma.

Case 2.—A man came to the Mayo Clinic on April 3, 1958, after a phone call from his physician requesting an emergency appointment, because it was the opinion of the consultants that the patient had a scirrhous carcinoma of the stomach of doubtful operability. The pa-

tient's symptoms were vague discomfort and fullness in the epigastrium. He had been able to eat about as usual. He had not suffered from nausea or vomiting, and his bowel movements were normal. Because of the gastric distress and indigestion, x-ray studies had been made of his stomach the preceding October and also in January, 1958, but the results were negative. However, x-ray studies done in April, 1958, at home, showed a filling lesion which was reported by the radiologist to be a scirrhous carcinoma of the stomach. The patient was placed on an ulcer diet for four weeks because of these symptoms. He then decided to come to the clinic for another opinion and to see if an operation would offer him any hope.

He stated that his normal weight was around 175 pounds, but his weight had increased to 186 pounds, probably owing to the midmeal feedings for the ulcer regimen. Physical examination did not show any significant abnormality. The x-ray films which he brought with him were interpreted by radiologists at the clinic as showing a filling constriction in the midportion and proximal end of the stomach. The x-ray of the thorax gave negative results. The hemoglobin and blood counts were normal. Gastric analysis revealed total acids of 42 units and free hydrochloric acid of 28 units.

Our x-ray examination showed evidence of an infiltrating carcinoma in the body of the stomach extending from about the level of the esophagogastric junction down to near the angle of the stomach (Fig. 2).

In view of x-ray studies at the clinic and the x-ray films the patient brought from home, the question was posed as to whether or not the lesion was operable. In such cases our policy has been to explore a lesion if other conditions permitted; therefore the patient was seen in surgical consultation and exploration was carried out on May 2, 1958. On first opening the abdomen nothing of significance could be seen. Two or three loops of small bowel were adherent to a right upper rectus incision, which was the site of a prior cholecystectomy. The stomach was then easily exposed and, in spite of most careful palpation, no lesion was detected within it. The glands in the region were not enlarged. The greater omentum was reflected off the transverse colon, but no disease process could be found. The surgeon finally decided to open the stomach to be sure that there was no such condition as carcinoma en nappe, which might account for the curious x-ray distortion in the absence of a palpable lesion. Absolutely nothing was found, and the abdomen was closed after exploration. A specimen from the stomach was removed, and it was entirely normal.

Comment

In a sense, these two patients presented comparable preoperative situations, namely, extensive lesions of the stomach. In Case 1 exploration elsewhere had confirmed the preoperative opinion of an extensive carcinoma. In Case 2, however, on exploration at the clinic no lesion was demonstrated. This case represents one of the exceedingly rare instances in which evidence of a nonexisting gastric deformity is apparent on the roentgenogram. Case 1 illustrates the rule that a positive diagnosis of cancer with our present knowledge must be based on accurate pathologic study. This is a recurring lesson that applies to all of us. Both cases illustrate the wisdom and fairness of surgical exploration, even though all preoperative signs are unfavorable. I have no explanation for the amazing and weird roentgenologic findings in Case 2. Yet if we had failed to heed the findings which were reported by radiologists both at the patient's home and at the clinic, the unproved diagnosis of cancer which did not exist would have remained. It is from such cases as these that cancer cures are obtained by quacks who prey on sorrow and fear.

Such medical reports are obtained and offered by the charlatan as proof that cancer did exist, and yet we, ourselves, are guilty if we have not pursued our study to its limits. Many well-documented instances are available of charlatans who have produced medical reports or photostatic copies of records in which a positive diagnosis of cancer has been made, and yet actually it was never proved.

The basic studies of cell structure originally carried out by Dr. William C. MacCarty, emeritus member of the Mayo Clinic staff, have led the way to advanced study and correct diagnosis of cancer. In a sense, all cytologic studies, which are now attracting so much attention, have their roots in his work.

Cases such as the two that I have reported emphasize vividly what Dr. MacCarty has taught over many years. The diagnosis of cancer must be made by the trained pathologist as he studies the cell. Both of these cases are offered not in any sense of criticism, but to increase our awareness of the differential problems in the diagnosis of gastric cancer and gastric ulcer and of the necessity of proving benignancy or malignancy of such lesions. Thereby we can help to avoid the inroads of state medicine and the claims of cures made by charlatans.

Hemangioma of the Ileum

HARRY B. NEEL, M.D.
Albert Lea, Minnesota

Presented at the meeting of the Minnesota Surgical Society, Rochester, Minnesota, May 9, 1958.

IN the great majority of cases, hemorrhage from the gastrointestinal tract originates in lesions of the esophagus, stomach or duodenum. In a smaller number of instances, leiomyomas, carcinomas and carcinoids of the small bowel, and Meckel's diverticula, are sources of gastrointestinal hemorrhage. One of the most unusual causes of bleeding from the gastrointestinal tract is hemangioma of the small bowel.

In 100 consecutive cases of gastrointestinal hemorrhage reported by Osborne and Dunphy,[1] ninety-nine were peptic or esophageal in origin; one was caused by a small bowel aneurysm. In a study of 673 cases of gastrointestinal hemorrhage at the Cook County Hospital, hemangioma was not mentioned. Shepherd[2] stated that prior to 1953 only two cases of hemangioma of the gastrointestinal tract had been recorded in the *British Journal of Surgery*. He reported a case of recurrent, severe hemorrhage from the intestine of a patient, aged twenty-two, with hemangioma of the ileum.

A hemangioma is a vascular lesion, congenital in origin, consisting of endothelium-lined spaces packed together and varying in size and shape. It is bluish or purplish in color, and soft and spongy. Blood can be squeezed from the cut or ulcerated surface. Gentry, Docherty and Clagett[3] have given the following classification of vascular lesions of the gastrointestinal tract:

A. Telangiectasis (hereditary and non-hereditary types)
B. Hemangioma
1. Capillary hemangioma (simplex, mostly single)
2. Mixed capillary and cavernous hemangioma
3. Cavernous hemangioma.
   a. Multiple phlebectasis (small cavernous)
   b. Simple polypoid (single cavernous)
   c. Diffuse expansive (single contiguous)
   d. Diffuse expansive (multiple non-contigous)

In the series of benign tumors of the small bowel reported by Olson, Docherty and Gray,[4] hemangioma was the rarest. Only four of seventy-seven tumors were hemangiomas; only two of these four produced symptoms. From one there was bleeding, and the other produced obstruction.

Raiford[5] reported eighty-eight cases of tumors of the small intestine collected from 11,500 autopsies and 45,000 surgical specimens. There were three hemangiomas. In a review of 1,400,000 case records, Gentry, Docherty and Clagett[3] found 106 vascular lesions of the gastrointestinal tract, forty-six of which were observed at the time of surgical treatment.

Rarely is the diagnosis of hemangioma of the intestinal tract made preoperatively. Hemorrhage and obstructive symptoms are the most common manifestations. Madell[6] has emphasized the diagnostic value of unusual localized clusters of phleboliths in the abdomen as a sign of unsuspected hemangioma of the ileum and mesentery. Goldfarb, Gould and Eickner[7] have reported the case of a white man, aged thirty-two, who, after many hospital admissions because of anemia and weakness over a period of ten years, was found by x-ray examination to have a polypoid alteration of the mucosal pattern in a short segment of the proximal ileum. At operation an angiomatous mass was found.

The following case report illustrates some of the interesting features of this unusual lesion.

Case Report

A white man, aged fifty, was admitted to the hospital on August 11, 1957 at 10:15 p.m. During the morning he had noticed some blood in his stool. Throughout the day he continued to bleed from the bowel, had five or more stools, and the blood was both dark and bright. He became "weak and wobbly," his heart beat rapidly and he became faint. He did not vomit.

On examination, the patient was found to be very obese. He was alert, cooperative, and pale. The pulse rate was 92 per minute. The blood pressure was 82/46 mm. of mercury. The abdomen was rounded, symmetrical and there was a McBurney's incision scar. There was slight tenderness in the epigastrium. Rectal examination was negative except for the presence of tarry stool.

The results of laboratory examination were as follows: Hgb. 9.45 gm./100 cc., hematocrit 28 per cent, leukocytes 11,450 per cu. mm. Urinalysis was negative except for the presence of an occasional hyaline cast. X-ray of the chest was negative.

This patient had been under our observation for many years. He was known to have a duodenal ulcer

for which he had been treated medically. As recently as February 29, 1956, the roentgenologist reported, "Duodenal ulcer with crater and marked deformity of the duodenal bulb."

It was assumed that the gastrointestinal hemorrhage originated in the duodenal ulcer. Medical treatment was instituted and the patient was given a transfusion of 500 cc. of blood.

On August 13, the patient felt good, his pulse rate was slow, the hemoglobin was 9.15 gm./100 cc. and the hematocrit 24 per cent.

At 4 p.m. on August 14, the patient became faint, weak and nauseated but he did not vomit. He was found to be in mild shock with a hemoglobin of 7.1 gm. and hematocrit of 20 per cent. On this day and the following day, 3,000 cc. of blood were administered. The pulse rate remained between 120 and 130 per minute and the blood pressure varied from 98/54 to 120/80 mm. of mercury. The hemoglobin dropped to 6.85 gm. and the hematocrit to 20 per cent. At 3 P.M. on August 15, the patient was taken to the operating room.

Under general anesthesia an upper midline incision was made. On inspection of the duodenum no evidence of recent activity was found and the scarring was not as great as anticipated. There was no blood in the stomach or in the upper reaches of the small intestine. There was a great deal of blood in the colon and in the lower segments of the small bowel, however. There was no Meckel's diverticulum. An examination of the small bowel was begun and in about the middle of the ileum there was an area in which the blood vessels beneath the serosa were dilated and there was slight thickening of the bowel wall. This segment of ileum was resected and continuity was re-established by end-to-end anastomosis. The wound was closed anatomically. During the procedure, a transfusion of 500 cc. of blood was continued, bringing the total amount of blood received to 4000 cc.

Convalescence was essentially uneventful. The patient was dismissed from the hospital on August 23 with a hemoglobin of 11.3 gm. and a hematocrit of 35 per cent. He has remained well.

The pathologist, Dr. E. C. Menefee, gave the following report: The specimen consists of 8 cm. of ileum. Along the mesenteric edge there is a loose network of greatly enlarged blood vessels extending up the wall of the bowel over an area measuring 2 x 1.5 cm. There is some irregular thickening in the bowel wall palpable from the outside. There are two submucosal nodules, one 0.5 cm. in diameter and the other measures 1 x 1.5 cm. These are visualized through the mucosa as dark purplish areas. On the surface of the larger mass there is a small defect in the mucosa through which old blood oozes. When these lesions are cut across they appear to be submucosal hematomas. Microscopically, the enlarged vessels are seen to have a capillary structure consisting only of endothelial cells and a small amount of loose connective tissue about them. The submucosal nodules are hematomas. The remainder of the bowel appears essentially normal.

Diagnosis.—Subserosal capillary hemangioma and submucosal hemorrhages with one area of mucosal ulceration.

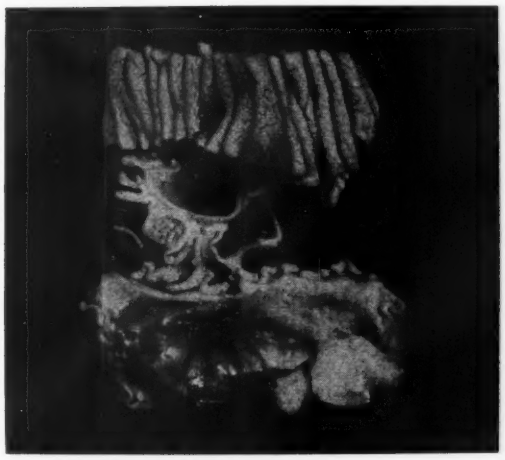

Fig. 1. Segment of ileum, 8 centimeters in length, containing submucosal hemangiomas.

Summary

Hemangioma of the gastrointestinal tract is a rare lesion. Hemorrhage and obstruction are the most common symptoms. Preoperative diagnosis is difficult but not impossible in some cases in which a cluster of phleboliths can be demonstrated by x-ray. A case is reported in which a massive gastrointestinal hemorrhage in a patient with a known ulcer was thought to be peptic in origin but proved to be from a capillary hemangioma of the ileum. Resection of the lesion was followed by complete recovery.

Delivery by Cesarean Section After Strassmann's Operation for a Bicornuate Uterus

WALTER A. BAER, M.D.
Saint Paul, Minnesota

THE obstetrical significance of a bicornuate uterus is often minimized. The deformed uterus, resulting from faulty midline fusion of the Müllerian ducts, has a poor gestational capacity. The result is a high incidence of abortion, prematurity and fetal loss.[1] Strassmann[2] with his unification operation wanted to help those women to become mothers.

Not every double uterus requires unification; about 30 per cent of women with a split uterus are fertile and carry to term, but various complications like premature labor, postpartum hemorrhage, prolapsed cord and retained placenta may occur and should be anticipated. The main indication for the Strassmann's operation is habitual abortion. Two abortions are enough to justify the operation.[2] When a patient presents herself with the history of habitual abortions at the third to the sixth month of pregnancy we have a strong suspicion of a malformation of the uterus. The following case report illustrates these criteria.

Case Report

Mrs. B. I., aged thirty-one, married for seven years, had been treated for infertility by specialists for six years. She presented problems of habitual abortions. She had one abortion after twenty-five weeks, one after fourteen and another abortion after fifteen weeks of pregnancy. The last two abortions happened within one year and each was followed by dilatation and curettage. Her double uterus had not been detected.

The patient consulted me on June 30, 1953, discouraged but still hopeful about having children. Physical examination gave essentially negative findings but the hystero-salpingogram revealed a uterus bicornis unicollis and patency of the tubes (Fig. 1).

Mrs. B. I. underwent surgery on October 4, 1953, with the performance of the Strassmann operation (Figs. 2-5). The uterine bodies were incised along the median ridges (Fig. 2). The cavities were opened all the way down into the common cervix and the septum removed (Fig. 3). The transverse incision was converted into an anterior-posterior suture line (Figs. 4-5). By this method the raw surfaces, which were created by excising the partition, were kept away from each other. This is the secret of the success. One layer of interrupted mattress sutures was used to close the incision. A single uterine cavity with normal reproductive space was obtained by this operation[2] revealed in the postoperative hystero-salpingogram (Fig. 6).

Our patient became pregnant about one year after surgery. Her pregnancy was undisturbed. The fetal head was not engaged at the term of pregnancy, the pelvic measurements were adequate. We expected complications in an elderly primipara. We preferred a delivery by a low cervical Cesarean section. A living healthy boy of seven pounds and three ounces was delivered. A careful examination of the uterine walls during the operation revealed that the placenta was adherent to the fundus and the fundus muscle was extremely thin. A previous Strassmann's operation is actually not an indication for a Cesarean section, but the implantation of the placenta in the scar area provides a condition of a possible uterine rupture.

Discussion

Strassmann's operation is relatively simple and is usually well tolerated. It is a constructive procedure which provides a physiologic union that nature forgot to complete. It should be noted that in a case where there is a double vagina and a double cervix, a vaginal approach to sever the septa between these organs has to precede the

Presented at the meeting of the Minnesota Obstetrical and Gynecological Society, Rochester, Minnesota, May 3, 1958.

abdominal operation. A waiting period of at least six months after surgery is recommended before the patient becomes pregnant.

would be a great fetal salvage[3] along with the rewards of parenthood for some otherwise infertile couples.

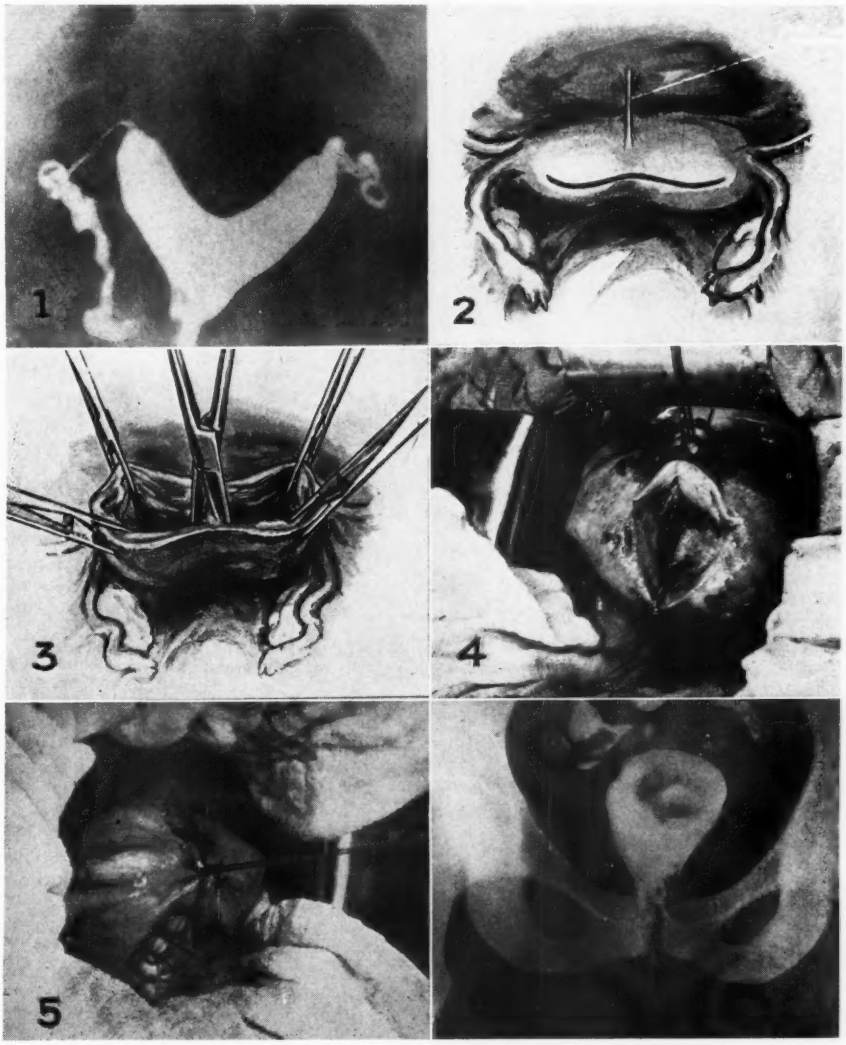

Fig. 1. Hystero-salpingogram revealing a uterus bicornis unicollis and patency of the tubes.
Fig. 2. Illustration of incision along the median ridges of the uterus.
Fig. 3. Illustrates the opening of cavity and removal of the septum.
Fig. 4. Transverse incision being converted into an anterior-posterior suture line.
Fig. 5. Conversion into anterior-posterior suture line.
Fig. 6. Hystero-salpingogram revealing a single uterine cavity with normal reproductive space.

The occurrence of uterine deformity is not rare and those physicians called upon to perform obstetric practice (both general practitioners and specialists) should be prepared to recognize such malformation early in their study of women who present a history of repeated abortions. The result

Fatal Bone Marrow Aplasia Associated with Celontin® Therapy

ROBERT A. GREEN, M.D.
MAURICE G. GILBERT, M.D.
Minneapolis, Minnesota

ANTICONVULSANT drugs which are free of side effects have not yet been discovered. Although some are described as "risk" drugs in the sense that they produce more frequent and more serious side effects than others, nevertheless they should all be used with caution and invariably under strict supervision. Any deviation from such procedure on the part of patient or physician may lead to disaster.

The similarity of chemical structure of the commonly used anticonvulsants has been noted by Zimmerman[1] and the fact that toxic reactions may occur from any of them probably can be explained on the basis of this similarity of molecular composition (Fig. 1). It appears that the addition of methyl groups (example: Tridione®) or combinations of methyl and phenyl groups (Mesantoin®, Celontin®) * may increase the incidence of toxic reactions.

Among more recent drugs with anticonvulsant activity and greater margins of safety, the succinimides appear to be quite effective.[2] The two which have had widest clinical application are Milontin® (n-methyl-a-phenylsuccinimide),[1] and Celontin, (n-methyl-a, a-methylphenyl succinimide) which was first reported by Zimmerman and Burgemeister.[3] Milontin has been reported to have "relatively low toxicity."[3] Celontin has been reported to produce greater toxic side effects than Milontin, but the therapeutic advantage has been

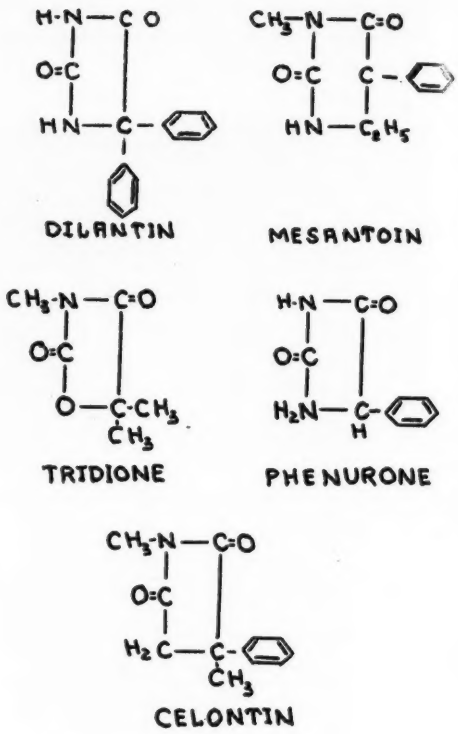

Fig. 1. Clinical structure of five commonly used anticonvulsants.

considered to outweigh this disadvantage. The incidence of toxic reactions to Celontin was 11 per cent in a series of 100 cases and of these there were no reported instances of blood dyscrasias.[4] To the writer's knowledge, no fatal reaction to this drug has been reported to date.

The following is a case in which death was considered to be due to bone marrow aplasia induced by Celontin.

Case Report

The patient, a thirty-five-year old, single woman, had a left radical mastectomy in December, 1954, for carcinoma. She was quite well until the early fall of 1956 when she developed an ataxic gait and slurring speech. A neurologist made a diagnosis of probable metastasis to the nervous system, particularly to the meninges in the region of the cerebellum, on the basis of widespread abnormalities on neurologic examination and the finding of an elevated spinal fluid protein. Bilateral oöphorectomy was done in January, 1957, but this failed to improve her status and the neurological symptoms became worse.

*Celontin® is a product of Parke, Davis & Co., Detroit, Michigan.

In May, 1957, she was examined elsewhere and it was the opinion then that the diagnosis of metastatic disease could not be substantiated but rather that she had a type of cerebellar ataxia of uncertain etiology (inflammatory, demyelinating, or degenerative).

Because of myoclonic jerking which had developed, she was started on Celontin in late May, 1957, in dosage of 600-900 mg. daily. Her myoclonia and speech both improved on this therapy. The dose was increased to 1200 mg. daily for a short period of time in June but the patient reduced it to the former dose because she thought she was too drowsy and "sick" to take more. Throughout this time she had endless complaints referrable to almost every system of the body, was constantly depressed, tearful and anxious. Other medications given for short periods for symptomatic relief were Donnatal®, Probanthine®, Premarin® and occasional doses of meprobamate.

On September 14, 1957 she was admitted to the hospital for observation and at this time the hemoglobin was found to be 2.5 gm. There was no evidence of blood loss. The white count was 4,200 with 59 per cent lymphocytes and 41 per cent neutrophiles. Marked thrombocytopenia was noted in the peripheral smear. Despite seven units of whole blood and large doses of prednisone, her hemoglobin rose by the fourth day to only 8 gm. and the white count had fallen to 800 with 64 per cent lymphocytes and 36 per cent neutrophiles. The platelet count was 16,000 on direct count and virtually none were seen on smear examination. At this time she began to show extensive hemorrhagic phenomena. Sections and smears of the bone marrow showed nearly complete hypoplasia, consisting almost entirely of lymphocytes, plasma cells and some tissue mast cells. Virtually no normoblasts or developing granulocytes were found.

On September 18, she had a grand mal convulsion, failed to regain consciousness and expired on the following day. Postmortem examination showed hemorrhages into the heart, lungs, abdominal viscera, kidneys and bladder. Extensive subarachnoid hemorrhage was present over the left temperoparietal area and diffuse petechial hemorrhages were found throughout the brain substance. No central nervous system or other metastases were found. Unfortunately the cerebellar pathology was not described.

Comment

It appears from this case that Celontin is capable of producing fatal marrow injury. It appears equally obvious that such an outcome might have been prevented had appropriate observations been made to detect early signs of bone marrow toxicity. Rather than to condemn the use of a valuable drug, this case report serves to emphasize the importance of being ever-mindful of the potential toxicity of such drugs and of making those observations which will detect toxicity at early and reversible stages.

OUR AMA HOUSE OF DELEGATES AND MEDICAL POLITICIANS

If you are a "doubting Thomas" concerning the contributions to Medicine by the American Medical Association, you can afford one or two days of your professional life visiting selected reference committee hearings and at least a part of the session of the "House." To organize this study economically you should request by mail in advance of the meeting a list of the fifteen or more resolutions submitted by the various State Medical Societies for consideration by the House of Delegates. On the day or two prior to the reference committee meetings, you might seek out delegates of State Medical Associations submitting resolutions in which you are particularly interested. Here is a source of background information on deliberations of many physicians on county and state levels sometimes involving several states and frequently over an interval of years. On the proper day, budget your time to cover several of the reference committee hearings by checking the order of presentation of the various resolutions to which you are particularly attracted. If you wish time to mix an exposure to the advancements in medical science at the AMA meeting with your personalized introduction to the business and political side of medicine, choose the proper part of the House of Delegates meeting which you wish to attend on the following day.

Whether you are a research professor in one of the basic disciplines of medicine or a busy physician in the largest or smallest community in the state as a neophyte, you are in for a pleasing surprise and a lasting conviction. Although mistakes could be made even with such thorough discussions and democratic procedures the overwhelming chances are: first, that the medical care of the people will be improved or not altered by the final decisions of the House of Delegates and, second, that the physicians of the country have been properly represented. Any complaints to the contrary are most likely from physicians "too busy" to attend a "political" meeting or whose opinions are not in agreement with more than a small minority. Thirdly, you will realize beyond a doubt that the "politically" inclined physician is making every bit as important a contribution to the medical care of the future as the physician devoted to medical research with its alleged low financial returns or the busy and successful practitioner. In both of these groups, there are many who pride themselves on their strict attention to medical science and belittle the "self-seeking" intrests of the medical politician. Is there a little self-sanctioned dishonesty in all of us?

My hat is off to the productive, logical, honest, yes—often altruistic, medical politician who is also devoted to the best possible care of his patients. The chances are, in these days of two diametrically opposing political forces, that he will make a greater contribution to his fellow man than any of the rest of us physicians. He frequently makes a greater personal sacrifice in his efforts with a much smaller chance of gaining prestige and security than any of us.

While we are in a philosophical vein, let us not confuse the picture with theoretical values. The changes of our contributing materially or metaphysically after death are about five times less than that of a dead horse. Best we recall the saying of Emerson to the effect that men can be divided into two groups, the doers and those who sit back and criticize. Today, most of us can do more than provide security for ourselves through doing well by our patients, and our teaching or our research. If we have decided that our selected occupation in medicine requires our entire time and mental effort for a maximum contribution in this brief life, then let us at least boost the good medical politician.

PROPOSED CHANGES IN CONSIDERATION OF RESOLUTIONS BY THE HOUSE OF DELEGATES, MSMA

Through the years, the resolutions considered by the House of Delegates of the Minnesota State Medical Association have become more numerous and have assumed expanding implications. These changes reflect medicine's greater complexity and

its more numerous contacts with other facets of the society in which we live. Resolutions adopted by our House of Delegates reflect the opinion of that body and of the entire Minnesota State Medical Association. It is the responsibility of the House of Delegates, therefore, to be assured that each resolution receives sufficient consideration and thoughtful study for a sound decision concerning any action to be taken.

Heretofore, resolutions often have been received no earlier than the initial session of the House of Delegates. On occasion, a resolution has reached a committee only after it has adjourned. With this situation, it is remarkable indeed that the resolutions committees in recent years have acted with such wisdom.

Resolutions may contain only material of an essentially noncontroversial nature; under such circumstances, prompt consideration will be achieved despite a last-minute introduction. On other occasions, however, careful study may be necessary to probe all of the implications of a resolution. A committee may wish to schedule hearings so that additional information and the views of other interested parties may be sought. In the past, interested delegates have, at times, first been apprised of a resolution only as it has been presented by a committee for final action in the House of Delegates. Interested delegates unaware of a resolution often have additional pertinent information. Such delegates might wish to attend scheduled hearings. Above all, it is invariably the wish of the delegates to be adequately informed in order to vote wisely and to contribute generously to the discussion of any proposed action.

For the above reasons, the format of the annual session of the House of Delegates will be modified, if such changes meet with the approval of the delegates to the Minnesota State Medical Association. These changes will enhance the opportunity for delegates to study material under consideration but will not limit the right of any person, group or society to exercise its privilege of submitting resolutions for consideration by the entire House of Delegates. Such changes will make our procedure for considering resolutions similar to that followed by the House of Delegates of the American Medical Association.

It is requested that resolutions be submitted to the office of the Minnesota State Medical Association no later than 2 weeks prior to the opening session of the House of Delegates. This is the minimal time required for material to be duplicated and mailed to delegates with the assurance of its arrival in adequate time. Likewise, accompanying each resolution will be a statement as to the reference committee to which a resolution has been assigned. Such a statement will be helpful because reference committees customarily hold many of their deliberations prior to the opening session of the House of Delegates. At the opening session of the House of Delegates, each resolution already distributed will be read by title only, with mention being made of the committee charged with its consideration.

Resolutions that have been received too late for printing and distribution to the delegates will be read in their entirety at the opening session of the House. The committee to consider them will be assigned at the time of this reading.

Resolutions received late in the annual session of the House of Delegates still may be considered, provided time is sufficient for an adequate committee hearing of the resolution. The committee studying a resolution may recommend its adoption, its rejection, that no action be taken, or that action be deferred until the next meeting of the House of Delegates if, in the judgment of the committee, inadequate time exists for study of the measure.

It is hoped that the effectiveness of the House of Delegates may be enhanced by these proposed measures.

HADDON M. CARRYER, M.D.,
Speaker, House of Delegates, MSMA

THE VALUE OF STUDIES BY COMMITTEES OF THE MINNESOTA STATE MEDICAL ASSOCIATION

Members of the Minnesota State Medical Association generally do not appreciate the fact that numerous committees put in many hours of cooperative effort in worth-while studies. In the November issue of MINNESOTA MEDICINE, a report on cardiovascular disease in industry† presented some thought-provoking facts regarding policies of rehabilitation of cardiac patients. As industry represents an increasingly larger portion of the working population of our state, the policies that were reported on will assume greater importance.

†Mathy, W. E.: Survey of "cardiovascular disease in industry" in the state of Minnesota. Minnesota Med., 41:805-811 (Nov.) 1958.

This study was conducted by the Minnesota Department of Health, in conjunction with the Heart and Tuberculosis Rehabilitation Committee of the Minnesota State Medical Association. This report gives some insight into the methods used to assess certain aspects of the health of our populace. Recommendations in the published report for improvement of legal tools and social attitudes concerning the responsibility for the health and welfare of workers in industry are a result of this study. The medical profession should take a leading role in decisions regarding policies of rehabilitation. Only by the accumulation of facts can authoritative recommendations be given to those responsible for the employment of this important segment of the population.

This committee of our state medical society is to be commended for this interesting investigation. Their report should set an example for other committees for bringing information directly to the members of the state association. It is hoped that this and similar future reports will stimulate more Minnesota physicians to better citizenship through activities in the state medical association that serve the state as a whole.

R. Drew Miller, M.D.

ADRENOCORTICAL STEROIDS

Allergic manifestations are protean, ranging from the relatively minor discomforts or cosmetically objectionable skin conditions to life threatening anaphylactic shock and bronchial asthma. Many agents, such as the antihistamines, have found a well deserved place in the symptomatic control of minor allergic conditions, but it was not until the appearance of the adrenocortical steroids that all allergic conditions could be satisfactorily controlled.

All of the corticoids have been widely applied in allergic disorders, and the response to this form of therapy has been very gratifying. In many cases, the duration of treatment is so brief that physiologic hormonal side effects do not develop even with the short term use of the older steroids, cortisone and hydrocortisone. However, in certain cases, long-term therapy of allergies is necessary and side effects sooner or later develop. It may be of some interest to review briefly two papers on the management of allergic disorders with the newer corticoids. Grater (Antibiotic Medicine and Clinical Therapy, February, 1958) treated 115 cases of asthma, rhinitis, and dermatitis with methylprednisolone, of whom 107 had a favorable response. Side effects were limited to six patients and these were all of a very minor nature. He felt the potency of this corticoid was one and one-half times that of prednisolone.

Sherwood and Cook (*Journal of Allergy*, March, 1957) reported on the use of triamcinolone in a series of seventeen patients with asthma or rhinitis, and were able to observe a satisfactory clinical response, and established increased potency associated with a low incidence of side effects. Weight loss of a marked degree (10½ pounds) was, however, noted in one patient. This confirms the observations of Hellman and his associates (American Rheumatism Association meeting, Bethesda, November, 1956).

These studies serve to focus attention on the increased potency, high therapeutic effectiveness and low incidence of side effects seen with new corticoids.

The mechanism of action of the corticoids in quieting the allergic response is a very fascinating one and has been illustrated beautifully by DiRaimando and Forsham. Following the fixation of antigen and antibody to the cells, histamine-like substances are produced with resultant swelling of the cells and histamine-like effects on distant sites. The presence of excess amounts of hydrocortisone reduces the production of these histamine-like substances and thereby prevents changes both within the cell and also in the more distal structures.

The corticosteroids have enjoyed a wide and enthusiastic application in the field of ophthalmology, both topically and systemically. In general, the systemic use of these compounds has been limited to inflammatory diseases of the posterior segment, although certain workers have employed them for allergic conditions of the anterior segment which were refractory to topically applied steroids. The acute inflammatory lesions of the posterior segment respond rapidly, the chronic types demand more prolonged therapy often at higher dosage levels. Here again the newer corticoids, such as methylprednisolone, by virtue of their lower incidence of side effects offer definite advantages to the patient.

Systemic lupus erythematosus has become recognized over the past decade to be a much more common condition. The discovery of the L.E. cell and its diagnostic value in doubtful cases, fol-

This is the third of four editorials on steroid therapy.

lowed by evidence of the ability of corticotropin and cortisone to induce remissions has led to a greater interest in this disease. Systemic lupus erythematosus is characteristically a chronic disease, often subject to spontaneous remissions, but almost invariably fatal in its outcome. Despite the ultimate result much can be done to aid these patients. The use of adrenocortical steroids in systemic lupus erythematosus often results in a prompt improvement in the clinical picture, followed at length by an improvement in laboratory findings. The dosage of corticoids necessary to produce this picture of a clinical and laboratory remission has often been somewhat startling—doses up to 3,500 mg. per day of cortisone being used on occasion. Needless to say, doses of this magnitude rapidly resulted in the development of many of the more severe side effects of steroid therapy. Even with the newer corticoids, prolonged therapy at such high levels must inevitably result in the appearance of these physiologic manifestations, but it is encouraging to note that thus far they do exhibit adequate control of the disease and show a tendency to spare the patient these side effects to a greater degree.

The use of the adrenocortical steroids has extended into many other fields and to many other diseases such as acute rheumatic fever, psoriasis, intractable cardiac edema, supportive therapy in severe fulminating infections, leukemia, malignancies, the adrenogenital syndrome to mention but a few. The confines of space prohibit a discussion of each of these diseases individually, but again it cannot be doubted that increased potency and a reduced incidence of side effects make the newer corticoids more potentially acceptable in the management of these conditions.

NUCLEAR POWER AND FREE ENTERPRISE

Electrical Industry

"A political stranglehold on commercial atomic energy could eventually spell the doom of private enterprise as the free world has known it," the Guaranty Trust Company of New York warned recently.

Government power advocates are conducting a systematic campaign to obtain large sums of public money for unnecessary government nuclear energy projects. They aim to draw the government deeper into the electric power business in competition with investor-owned electric companies.

The *New York Daily News* has called these public power moves an open attempt to create a public nuclear power empire like TVA.

Investor-owned electric companies are doing the job of developing nuclear power in this country. Today sixty-nine investor-owned electric companies are participating in fourteen projects which are expected to have a generating capacity of more than 1.5 million kilowatts, constructed at a cost of well over $400 million.

At the current pace of nuclear expansion by private enterprise, it is estimated that by 1975, the total outlay for nuclear energy power plants will be more than $8 billion.

Regarding unnecessary government spending on nuclear power projects, The Guaranty Trust Company says.

> "If economic experience can be taken as a guide, the path of progress lies in further steps toward a regime of free enterprise in atomic-power development.
>
> "It certainly does not lie in the squandering of resources and energies in the establishment of government-in-business that could eventually fasten a socialist dictatorship upon the country's economic life."

DONALD UNDERWOOD

HEALTH CARE FOR OUR SENIOR CITIZENS

Prepayment of medical care for the elderly has long been a matter of urgent and continuing concern to the medical profession and its Blue Shield Plans. Within the past year, however, this problem has been made something of a political issue through the introduction of such legislation as the Forand Bill, which, if adopted, might radically affect the future of the entire voluntary health care movement in America.

What are the facts concerning Blue Shield coverage of senior citizens? What has the medical profession accomplished, through Blue Shield, to meet this challenge?

The answers to these questions will be of immediate interest as a New Congress meets—a Congress in which social welfare programs are certain to be accorded a high priority.

Some of these answers, as reported recently to AMA Council on Medical Service by the national association of Blue Shield Plans, are truly encouraging.

For example, in 1951, among a total Blue Shield enrollment of 21 million persons, nearly a million,

or a little less than 5 per cent, were over sixty-five years of age. Six years later, in 1957, among the total of 40 million persons enrolled, 2½ million (6.5 per cent) were over age sixty-five. Thus, in these six years, the number of Blue Shield members over sixty-five increased 170 per cent, while total Blue Shield enrollment increased only about 85 per cent.

Attention was called also to the fact that of the total number of people past sixty-five who have medical-surgical insurance coverage, about two-thirds are covered by Blue Shield.

Of all the people in the United States, it is estimated currently that about 15 million are over sixty-five years old, and are not cared for by an established institution or agency. This represents approximately 8 per cent of the total population. Thus Blue Shield's ratio of 6.5 per cent over age sixty-five is reasonably related even now to the ratio of the total population in that group—and is rapidly approaching parity with it.

Blue Shield has always sought to serve medicine's inescapable responsibility to the whole community. It was until recently almost an exclusively Blue Shield feature that any member on retirement, or on leaving an insured group, could retain his coverage by "conversion" to a "direct-pay" basis. Few Plans impose any age limits on initial group enrollment, and an increasing number of Plans are accepting non-group members regardless of age.

In Minnesota, an analysis based upon a 10 per cent sampling of all contracts in effect January 1, 1958, showed that 6.9 per cent of all Minnesota Blue Shield participant subscribers were sixty-five years of age or older. For Minnesota Blue Shield, there are no age limits for group subscribers. Persons up to age sixty-five years who provide a satisfactory health statement are eligible for non-group Blue Shield enrollment in Minnesota. When once enrolled, Minnesota Blue Shield coverage is never cancelled because of age. Retirees are allowed to convert to non-group contracts with full contract coverage.

MEASLES

Deaths caused by measles outnumbered poliomyelitis deaths in 1957, for the first time in fourteen years. In 1957, there were an estimated 410 measles deaths, 220 from polio. In 1944: measles 1,923; polio 1,361. Number of measles cases reported through late November, 1958: 733,000—a sharp jump from the 464,000 cases reported in all of 1957. Drug companies hope to perfect measles vaccine within a year.—*AMA News.*

Minnesota State Board of Medical Examiners

DRUG ADDICT POSING AS PHYSICIAN GIVEN SEVEN-YEAR PRISON TERM

On December 8, 1958, Donald Gerald McGregor, forty-six years of age, 801 W. 3rd Street, Yankton, South Dakota, was sentenced by the Hon. Earl J. Lyons, Judge of the District Court of Hennepin County, to a term of not to exceed seven years in the State Prison at Stillwater for attempting to obtain narcotic drugs by fraud. Judge Lyons stated that pleas had been made to him on behalf of the defendant to place him in an institution for treatment but in view of the defendant's past record the Court did not feel justified in extending leniency. McGregor, who has convictions for forging narcotic prescriptions dating back to 1933, had previously entered a plea of guilty before Judge Lyons on October 28, 1958, to the charge on which he was sentenced.

The defendant was arrested on October 20, 1958, after asking for a "shot" of demerol or a prescription for demerol tablets at an Osseo, Minnesota, clinic where he represented himself as a doctor of medicine from Alma, Georgia, stating that he had retired from practice because of a heart condition. McGregor's request for narcotic drugs was not complied with, and a subsequent investigation revealed that he was not a doctor of medicine, the defendant was charged in a criminal complaint signed by a representative of the Minnesota State Board of Medical Examiners with fraudulently attempting to obtain narcotic drugs.

Upon being questioned by the Court before sentence was pronounced, McGregor stated that he was born in Seattle, Washington, on June 15, 1912. The defendant further said that after graduating from high school, he attended Pennsylvania State College where he studied chemistry. When asked what type of work he was trained in, McGregor admitted he was not a physician and gave his occupation as that of a mechanic specializing in the repairing of business machines.

Because of having prior felony convictions, the defendant could have been given a longer prison term as provided for by law if he had been charged with those convictions in this proceeding. However, this was not done because the authorities were of the opinion that a maximum sentence of seven years in prison was sufficiently severe to fit the crime in this case. The defendant's criminal record is as follows: December 11, 1933—placed on three years probation in San Francisco, California, for forgery, November 9, 1940—sentenced at Salt Lake City, Utah, to a term of two years in the United States Penitentiary at McNeil Island, Washington, for impersonating a federal officer. On November 20, 1945, and again on June 19, 1946, the defendant was given prison terms for forging narcotic prescriptions. On the first occasion, McGregor was sentenced to a term of fifteen months in the United States Penitentiary at Leavenworth, Kansas, and in 1946 he received a sentence of eighteen months in prison at McNeil Island, Washington. On March 24, 1949, at St. Louis, Missouri, the defendant was sent to the United States Public Health Center at Lexington, Kentucky, for a period of three years, and on December 8, 1955, McGregor was sentenced at Tampa, Florida, to serve two years in the State Prison at Raiford, Florida.

President's Letter

MEDICINE AND A MEDICALLY MINDED CONGRESS

The collective eyes and ears of the nation's medical profession are focused on the 86th Congress early in its two-year existence. Medical and public health legislation, which received only token attention in the 85th Congress in 1957-58, is expected to become an important item of business during the current session.

President Eisenhower, in his budget message, called for $77 billion budget, forecasting a spending cut of nearly $4 billion, and a possible surplus of $70 million. Various spokesmen in the predominantly Democratic congress have already expressed themselves as setting their sights beyond that amount.

The welfare of the senior citizen will continue to receive added attention. The Forand Bill for financing hospital-surgical care of all social security beneficiaries is expected to gain speedy momentum with the full blessings of the liberal elements of Congress. Labor has already gone on record earmarking passage of the Forand Bill a "must" for the present session of Congress. Some observers predict that the Eisenhower administration will introduce a watered-down version of the Forand Bill. However, the big push for enactment of this bill may be postponed until 1960, an election year ripened for harvest. Look for the introduction of bills which would grant subsidies or preferred treatment to voluntary non-profit health prepayment plans which encourage enrollment of older persons. Republicans and Democrats alike could give the nod to this type of legislation.

Passage of the AMA supported Jenkins-Keogh Bill will be urged by the American Thrift Assembly this session. The bill which passed the House last session, but got lost in the Senate, would grant the self-employed a tax status similar to that of corporation employees by allowing them to refer income tax payments on earnings placed in retirement plans.

Expect an extension of the doctor-draft. The current bill due to expire June 30 may be needed to bolster the dwindling ranks of M.D. volunteers in the military services.

Medicare's $72 million congressional appropriation will be far spent by the end of the current fiscal year, which ends June 30. A deficiency appropriation may be required to defray the deficit. At the same time, it could be a show-down involving the number of Medicare benefit restrictions imposed by the last Congress, particularly those which impose military medical care rather than free choice of private physicians and hospitals.

Whether U. S. grants should help subsidize ordinary operating expenses of medical schools or be limited to construction assistance is a question bound to confront legislators.

Look for the AFL-CIO to pressure enactment of U. S. Employees Health Insurance for the nation's more than half million civil service employees.

Minnesota Senator Hubert Humphrey will combine his joint efforts with other internationally minded congressional leaders to urge the stimulation of U. S. interests in the participation of world-wide medical research.

Regardless of the outcome of legislation, anticipated or unexpected, enacted by this Congress, the free practice of medicine in the United States is destined to follow a course of no return. Your diligent consideration will be required to keep abreast of medicine—1959 on the march.

MORE SOCIAL SECURITY MEANS A BIGGER STAFF

An estimated increase of approximately 3,000 additional staff workers will be required by the Bureau of Old Age and Survivors Insurance to process the increased work load due to the 1958 amendments to the Social Security Law. 1,600 Civil Service employes have already been hired. The remaining number will be required as the number of OASI recipients increases. These anticipated needs were recently disclosed by Health, Education and Welfare Secretary Flemming. It has been estimated that 12.3 million persons are now receiving OASI benefits.

STATE OF MEDICINE UNDER SOCIALIZATION IN ENGLAND

Following is a letter from a Northampton, England, doctor to the editor of the *British Medical Journal*. It points up the low state to which the medical profession has sunk in Great Britain under socialization.

SIR.—The refusal of the Government to allow us access to the courts is surely the final proof that we can expect no justice until we can negotiate from strength. Having been refused negotiation, arbitration, and now law, can we possibly regard the Royal Commission as anything but a time-occupying manoeuvre?

No other body of employes has been treated in this manner for many, many years, and to submit meekly yet again is to yield more power to our overlords and accept the will of dictatorship. This is no idle phrase. Since the lodging of our claim 2½ years ago, two steps only have been taken: The setting up of the Commission, and the 5% increase. Both of these decisions were entirely dictatorial; the profession was not consulted, the merits of the case not considered, and past promises disregarded. We acquiesced, and the power of the Government over us grew with each submission, so that when we claimed that last bastion of democracy, a court of law, that too was denied us.

Where do we go from here? One thing is certain—divided we fall. Yet so divided have we been that our leaders feel unable to take any major step without special conferences, referendums, et cetera, wasteful in time and money, and giving ample warning of our intentions. But if our leaders could be assured of our support, could have our unqualified pledge to take such action as they might recommend, then indeed they could negotiate as equals. In the end we must choose; either we trust those we elected to lead our erstwhile great profession or we abandon ourselves and all who come after us to the mercies of the politicians.

Will our leaders ask for such a pledge? Should they do so I believe the response would be overwhelming, and, given that, they assuredly have the ability to restore justice and fair dealing, and we have never looked for more.

Yours respectfully,
J. Leahy Taylor

INCREASED POPULATION MEANS INCREASED PROBLEMS

According to the Population Reference Bureau, the number of people on earth increased in 1958 by 47,000,000. This increase exceeds the total population of all the New England states, plus those of New York, New Jersey, Pennsylvania, and Maryland. In addition, the bureau points out that if the present birth rate continues, by 1980 the world population will be more than four billion, an overwhelming percentage of whom will be living in what are now known in the West, as under developed countries. How will this affect the future responsibilities of medicine? The Health News Institute points out that the nutritional problem in this prospect is obvious. Less apparent is the health problem. Millions of people will be huddled together under conditions which will be open invitations to epidemics and medical disaster.

In long-range anticipation of this population growth, a score or more of American pharmaceutical houses have in the past year announced plans to expand their overseas operations on five continents, building plants, hiring native personnel, with only American know-how in local charge.

DEATH TOLL DROP NOTED

The reduced death toll among women during pregnancy and child birth, may be ranked as an "almost unparalleled achievement of medical progress," according to Health Information Foundation reports. The Foundation points out that the maternal mortality rate in this country has dropped 93 per cent in the last four decades—from sixty-one deaths per 10,000 live births in 1915 to 4.3 deaths in 1957.

One maternal death occurs in approximately 2,300 live births today, compared with one maternal death for each 165 live births in 1915. Last year, the foundation stated, 4,200,000 babies were born in the United States; there were 1,600 maternal deaths. Had the rate of one generation ago still prevailed, the number of maternal deaths would have run as high as 28,000.

In actual fact, pregnancy and childbirth have become very minor causes of death in this country, accounting for only one-tenth of 1 per cent of all deaths and only 4 per cent of all deaths among women of childbearing age. Accidents alone cause three times the number of deaths among women of reproductive age as maternity does.

Although maternal death rates have dropped among women of all the childbearing age groups, the greatest gains have been made by women at the younger ages. The safest age group is that between twenty and twenty-four years, only 3.2 maternal deaths per 10,000 live births occur in this group. Next come women under twenty and those in the twenty-five to twenty-nine groups, each with a rate of 4.3.

Birth order is also related to safety in childbearing the foundation added. "Second births are safer than first, and third even safer than second. With fourth births maternal mortality rises again, and the hazards connected with later births begin to exceed even those in the first."

"Much of the improvement in childbirth safety," says H.I.F., "is attributable to the high level of prenatal care and hospitalization for birth now customary in this country." In 1955, 94 per cent of all live births occurred in hospitals, and 97 per cent of all births came with a physician in attendance.

The basis for today's standards of childbirth safety was established during the 1920's, the foundation pointed out. During this period, great gains were made in hospital standards of sanitation, medical research, postgraduate instruction in obstetrics, and knowledge of nutrition, obstetrical surgery, and anesthesia. Later, the improvement accelerated with the introduction of the sulfas, penicillin, and the broad-spectrum antibiotics.

If present trends continue, the Foundation concluded, "risk may be virtually eliminated from childbearing. The lowest maternal mortality rates achieved anywhere today may come to seem high, as those of former years seem now."

U. S. FUNDS FOR MEDICAL SCHOOLS?

Could this prove contagious? A dean from one of the nation's leading medical schools, has recently suggested that the time has arrived for the Treasury to help defray operating expenses of medical schools as well as subsidize physical plant improvement. This was the opinion expressed recently by Dr. Lowell T. Coggeshall, dean of the University of Chicago Medical School. The remarks of Dr. Coggeshall were part of his presidential address at the 69th Annual Meeting of the Association of American Medical Colleges held in Philadelphia. The University of Chicago Medical dean minimized fears of Federal control sequelae.

Observers have pointed out that while the Coggeshall stand does not bind AAMC, its executive council has authorized the staff to launch a one-year comprehensive study of the costs and financing of medical training. Data will be ready for Congressional inquirers.

HEW SECRETARY FLEMMING WANTS MORE DATA ON MEDICAL EDUCATION

In another development, Secretary Flemming of the Department of Health, Education and Welfare, during one of a series of conferences with health and welfare leaders, indicated he may ask various voluntary health agencies for their views on medical education. He particularly wants to know what they consider to be "fair shares": of medical education to be met by federal, state and local governments and private groups and institutions.

Conference subjects included the need for attracting more and better young people to medical careers, in the face of competition from "space, rockets and engineering;" the problem of drawing talented researchers into medicine at the college level, also in the face of scientific competition; and need for compiling a complete inventory of both government and private medical research in all its aspects. Surgeon-General Burney said the latter task was beyond the capability of Public Health Service.

DOCTOR-PRESCRIBED TRAVEL IS TAX DEDUCTIBLE

A prescribed travel expense to visit a child in a treatment center may qualify as a tax deductible medical expense item if such travel is made on competent medical advice "as an essential part of

therapy and medical management," according to a new ruling by the Internal Revenue Service. Recently this ruling involving parents of a child under psychiatric therapy at a private treatment institution some distance from the parent's home was granted. The IRS decision was based on Rev. Rule No. 58-533.

HEALTH INSURANCE RECEIVES PUBLIC APPROVAL

Seven out of every ten persons with health insurance express "complete satisfaction" with it.

This is one major finding of "Public Attitudes Toward Health Insurance," a research study by Eliot Freidson and Jacob J. Feldman based on a Foundation-supported survey by the National Opinion Research Center of the University of Chicago.

The survey consisted of detailed interviews with a representative cross-section of the American public—almost 2,400 persons in all—as well as with some 500 doctors named by the public as their family physicians.

The NORC study, still in preparation, deals with a wide range of topics relative to health and health services. The Foundation's report is limited to what the public and family doctors said about voluntary health insurance.

At the time the survey was made, in 1955, two out of every three persons interviewed had some form of hospital, surgical, or medical insurance. Seven out of ten insured persons were completely satisfied with their policies. Even among the minority without health insurance, three out of five thought that such insurance was a good idea.

About a quarter of the insured persons mentioned specific ways in which they felt existing coverage could be improved. Common suggestions were that insurance should cover more services (such as doctors' home and office visits) and a higher proportion of the total bills for presently covered hospital-surgical services. One person in six complained that premiums were too high.

Does having health insurance make a difference in the way you are treated when sick? Almost four-fifths of the public said no, according to HIF. On the other hand, 94 per cent of the doctors interviewed believed that having insurance affects the way a *patient* behaves when ill.

Insured patients, family doctors said, are more willing to undergo needed hospitalization and surgical treatment, and are more likely to seek medical attention in time. Only one doctor in five felt that having health insurance encourages patients to get unnecessary medical care. And three out of five physicians claimed that their own handling of a case is *not* influenced by the fact that a patient is insured.

"The public's regular doctors appear less satisfied with present health insurance than are their patients," the HIF report states. When these doctors were asked whether insurance should cover any costs it doesn't cover now, "only 35 per cent expressed satisfaction with present benefits. Fifty-nine per cent felt that benefits should be increased."

What added benefits are needed, as these doctors see it? The main suggestion dealt with coverage of diagnostic procedures and medical care outside hospitals. A less urgent need, physicians said, was for extension of coverage of hospital and surgical services.

RURAL PHYSICIAN SURVEY MADE IN PENNSYLVANIA

Interesting are the results of a recently completed study entitled "Rural Physicians—Their Satisfaction with Medical Practice." The report of the study was presented by Dr. William G. Mather, Head of the Department of Agricultural Economics and Rural Sociology of the Pennsylvania State University, who directed the four-year study which was initiated by The Medical Society of the State of Pennsylvania.

These findings were presented at the Eighth Annual Public Relations Conference, held in conjunction with the 108th Annual Session of the Medical Society of the State of Pennsylvania.

The purpose of the survey was to learn more about the advantages and disadvantages of rural practice, in order to advise physicians in their choice of location as well as advise communities in their attraction or retention of physicians. The survey revealed that rural physicians are well satisfied with their place of practice and that, although rural practice is hard work, it is rewarding. In addition, the survey showed that almost all babies are now hospital delivered and few major surgeries are performed outside the hospital. The report stated the rural physician is called upon to complete automobile mileages from 10,000 to 30,000 miles a year. The report recommended that the further use of partnerships and clinics should be studied, as they could relieve the phy-

sician and allow time for study and recreation. The report also stated that a community seeking a physician should analyze itself, particularly with respect to its schools, churches, recreational life; its willingness to accept a newcomer of advanced and cultural standards; and the way in which the community is accustomed to support its hospitals.

Of the 662 Pennsylvania rural physicians studied, all but eleven were men, 93 per cent were married, 69 per cent were in the age group of thirty to fifty-four years, and 70 per cent had practiced only in their present location. More than 86 per cent were engaged in general practice and only 10 per cent were registered as specialists. Ninety per cent of Pennsylvania's rural physicians were born in the state.

AMA, AHA DENOUNCE LOOK HOSPITAL STORY

The American Hospital Association and the American Medical Association have jointly taken issue with an article on practices in hospitals which appeared in the February 3 issue of *Look* magazine.

A joint release was authorized by the organizations.

Dr. Crosby, Director of the American Hospital Association, wrote a letter to Vernon C. Myers, the magazine's publisher, commenting on the article by Roland H. Berg, *Look* medical editor. He said:

"One needn't believe that everything is perfect in our hospitals—as it is not in other public service programs—to conclude that the handling of an admittedly difficult problem by Mr. Berg and *Look* was most unfortunate."

Dr. Crosby termed the article's opening sentence—"A hospital is not a fit place in which to be sick"—as "an outrageous misstatement." He said:

"This statement is disproved by an abundance of evidence; the growing acceptance by the public of the hospital as the place to get well; the direct relationship between the drop in maternal mortality rates and the increasing frequency with which hospitalization is sought for child-birth."

Dr. Crosby told the *Look* publisher that although "Mr. Berg devotes much space to patient dissatisfaction . . . the very study he quotes is at odds with his findings." The study on five hospitals in California was sponsored by the California Medical Association. Dr. Crosby said 95 and 94 per cent of the patients in the two hospitals studied in greatest detail were generally satisfied with their care and treatment.

The AHA director pointed out that hospitals for the last decade, have been continuously striving "to keep abreast of the explosive growth in medical science and to bring those advantages to the American people." He observed:

"It is difficult to keep apace, to meet the demands of the patients and physicians for even better and ever more complex care and at the same time solve the subtle human relations problem in a hospital."

"I am fearful that you may have unwittingly intensified a problem already difficult enough," Dr. Crosby wrote. He added:

"Hospital administrators face the continuous problem of fitting inadequate amounts of money to increasing great needs. It is understandable that they trim in the area of scientific needs only as a last resort. We believe that there is a major national problem in the underfinancing of hospital care; a tremendous service deficit in our hospitals. The budgets are balanced somehow. We suspect that this balance is at the expense of the kind of hospital care that medicine and hospitals could provide and the kind of hospital care we believe that a properly educated public would finance."

Dr. F. J. L. Blasingame, executive vice president of the American Medical Association, speaking for the AMA, said:

"By taking isolated examples from a limited survey and drawing general inferences from them, *Look* not only has done a grave injustice to the medical profession and to hospitals but to the readers of the magazine.

"The blanket condemnation of all hospitals, based on a survey of five hospitals out of 5,640, is deplorable. Actually, the survey reported a tremendous degree of patient satisfaction, the lowest cited figure being 94%. This was not mentioned in the *Look* article.

"While the article purportedly calls for better physician-patient relationships, it actually harms the patient's confidence in the care he will receive from his physician and in the hospital, so essential for the best in medical care. The article cannot help but increase the natural insecurity of the afflicted and the suffering.

"The article also violates the basic concepts of sound reporting. Matters such as these cannot be considered adequately or accurately covered until both sides of the question are reported fidelity and without distortion.

"The medical and hospital professions have been sincere in devoting their efforts to a continuing program of self-improvement designed to benefit our patients. We welcome constructive suggestions to help us do even better. For the sake of our patients, we must object to those we believe will be harmful."

Public Health

MINNESOTA PUBLIC HEALTH CONFERENCE LAYS PLANS FOR 1959 PROGRAM

The Minnesota Public Health Conference at its twelfth annual meeting at the St. Paul Hotel, September 18 and 19, 1958, re-elected Robert D. Ragsdale, executive secretary of the Hennepin County Tuberculosis Association, as its 1959 president. Others elected were: Dr. Robert K. Anderson, St. Paul, first vice president; Mrs. Mildred Benson, St. Paul, second vice president; and Dr. Stewart C. Thomson, Minneapolis, treasurer. Dr. John Smiley, Dr. Henry Bauer, and Richard Bond, Minneapolis, and Richard Sha, Rochester, were elected to membership on the Conference executive committee. The organization will hold its 1959 annual meeting September 24-25 at the Radisson Hotel in Minneapolis.

Recipient of an honorary membership in the Minnesota Public Health Conference for "outstanding and meritorious achievement in public health in Minnesota," was Dr. Adolph G. Liedloff, retired Mankato, Minnesota, physician and health officer. The presentation was made at the Conference's annual Albert J. Chesley, M.D. Memorial Banquet, held September 19. Making the presentation was Dr. A. B. Rosenfield of the Minnesota Department of Health.

The eighty-year-old doctor retired as part-time district health officer of District II at Mankato, in February 1956 after nearly fifty years of service in public health. He was a charter member of the Minnesota Sanitary Conference which was organized in 1907. He served one term as president of the Sanitary Conference which later became the Minnesota Public Health Conference, an affiliate of the American Public Health Association.

Dr. Liedloff served as Blue Earth County health officer from 1932 until his appointment as District II health officer on a part-time basis on May 1, 1944. His appointment to the district office was repeatedly extended beyond the normal retirement age at the request of the late Dr. A. J. Chesley and other health department officials. In one such request, Dr. Chesley stated, "He is doing a splendid piece of work for us."

A 1902 graduate of the University of Minnesota Medical School, Dr. Liedloff practiced medicine in Mankato for forty-one years beginning in 1903. In 1952, he received a fifty-year award pin from the state medical association. He was also Blue Earth County coroner from 1908-1916 and served as a captain in the Mexican Border Service from 1916-1917 and as a major in the Army Medical Corps from 1917-1919. From 1935 to 1947, he was president of the Blue Earth County Health Association.

Dr. A. B. Rosenfield (left), Director of the Division of Special Services, Minnesota Department of Health, presents Dr. Adolph G. Liedloff, Mankato, Minnesota, physician with an honorary membership in the Minnesota Public Health Conference. The eighty-year-old retired physician and health officer devoted nearly fifty years of service to medicine and public health.

NEW TV CODE BANS "MEN IN WHITE"

Men in white who look like physicians or dentists on TV commercials may be on their way out of your living room, according to **Safeguard,** official publication of the Better Business Bureau.

The clamp-down refers to the tonic and toothpaste ads that try to lend credulity to messages delivered by dressing up actors as doctors or dentists and putting them in mock offices.

The Television Code Review Board of the National Association of Broadcasters has issued a ban on these ads. Previously, the board permitted such promotion as long as the words **"A Dramatization."** appeared for at least ten seconds on the screen.

The new ban precludes:

Appearances in ads of physicians, dentists or nurses, even though such portrayals are visual only.

Use of props or settings which might give viewers the impression the individual speaking is a member of the medical, dental, or nursing profession when, in fact, he is not.

References by announcers and TV pitchmen to scientific research, studies or surveys may be used only if there is actual evidence such took place, and is on record.

The board said filmed commercials, produced before June 18, 1958, could be used until January 1, 1959. No films newer than that may be used.

PRESS-PHYSICIAN SURVEY CITED

Findings of a recent survey of seventy-three newspaper editors and 320 physicians conducted by Professor Roy Carter of the University of North Carolina Journalism Department were as follows:

(1) More than one half of the editors did not know about local medical society's information services. The most frequent suggestion was that the society provide a list of spokesmen.

(2) Almost all of the editors believed that a press code would help, but only half of them were familiar with such a code.

(3) Only one third of the editors believed that adequate medical care was available for indigents.

In most cases medical society officers, public relations chairmen and older physicians included in the survey expressed fair treatment by the press. A society spokesman who had developed good relationships with newspapermen over a period of years was considered the ideal news contact by the majority of persons interviewed.

SURVEYS MAY HELP PATENT MEDICINE HUCKSTERS

Beware of surveys warns an editorial in **New York Medicine.** The editorial points out that the man in the white coat—due to intervention by medical societies, The Federal Trade Commission, and perhaps a rise in the conscience level of ethical TV broadcasters—is dwindling. However, the medical survey technique is now appearing and the insidious thing is that this is accomplished by the unthinking co-operation of physicians themselves.

Under the guise of scores of different titles with high sounding names like information bureaus, patent medicine drug companies are sending physicians questionnaires on their prescribing habits—what drugs they prescribe for what ailments. Usually these are sent on a nonpayment basis. However,

some of the more elaborate surveys will pay the physician for filling out the forms.

One end result is that we now have a new crop of patent medicine advertising on TV and radio the "Medical Survey says . . ." type of commercial. Another variation makes its pitch that Kokotomahawk or whatever the name, is just what the doctor ordered for it contains the ingredients which eight out of seven doctors recommend, according "to the latest survey."

This knowledge should at least forewarn the physician. In answering any survey on your prescription habits, make sure that the survey is under proper medical sponsorship and not just the screen for some clever advertising agency and patent medicine manufacturer.

Physicians can legitimately complain if white coat dramatizations fool the TV public on patent medicines. Physicians can blame no one but themselves if they fall for the "survey" type of advertising exploitation and provide the data that made the survey possible.

TEEN GROUP TO STUDY ALCOHOL AND HEALTH

Since alcoholism is considered more and more a medical problem, your society may be interested in working with a group that discourages drinking among teenagers. The group is Allied Youth, Inc., and its program attempts to show teens that alcohol and adolescents do not and need not mix. In February, Allied Youth groups in high schools all over the country will be studying "Alcohol-Adolescents and Health." Medical societies can help by supplying speakers, securing films and exhibits or just volunteering their services ahead of time for whatever the teens have in mind.

Allied Youth has as its fundamental, a solid core of students in each school who can prove to other teens that they don't need to drink to have a good time.

MICHIGAN OFFERS TRAINING FOR MEDICAL ASSISTANTS

A Medical Assistants Inservice Training Program has been developed by the University of Michigan. The project is sponsored by the Education Committee, Michigan State Medical Assistants Society.

The Michigan Medical Assistants Training Program includes an M.D. advisory committee to the medical assistants at the state and county levels.

The co-operating faculty includes The School of Business Administration, The School of Nursing Medical School, The Department of Psychology, and the College of Literature, Science, and the Arts of the University of Michigan.

Pilot courses will be offered in Battle Creek, Detroit, Flint, Jackson, Lansing, and Pontiac. These centers adjacent to Ann Arbor have been selected to give faculty members of the University the opportunity to work with medical assistants in the area in developing useful and usable course content. Upon completion of the pilot program, published courses of study will become the property of the Education Committee of the Michigan State Medical Assistants Society, to be used by that Committee as the basis for offering the inservice training program in centers throughout the State of Michigan.

Each course will meet for sixteen two-hour sessions. Courses will begin in late September and middle February of each year, generally on Thursday evenings and in the classroom of the nurses' home connected with a hospital in the course center. A fee of $27.00 per course will be charged.

Any member of the Michigan State Medical Assistants Society who has completed the full six courses will be registered with the Michigan State Medical Assistants Society and with the State Office of the Michigan Medical Society as a Certified Medical Assistant.

The Extension Service of The University of Michigan will award a certificate of completion to all students who satisfy minimum attendance requirements for five of the six courses.

Course descriptions include: Medical Information for Medical Assistants, Nursing Information for Medical Assistants, Law and Economics in Medical Office Administration, Medical Office Management, Psychology of Human Behavior and Dynamics of Human Behavior.

when psychic symptoms distort the picture

Dartal helps the patient reintegrate his mental processes

In everyday office practice as well as under hospital conditions Dartal is consistent in its effects as few tranquilizers are.

Dartal promotes emotional balance

Dartal effectively decreases or relieves emotional hyperactivity and psychomotor excitement.

Dartal is unusually safe

At a recent symposium, leading hepatologists* concluded that Dartal is not icterogenic or hepatotoxic.

Dartal is effective at low dosage

One 2-mg. tablet q.i.d. or one 5-mg. tablet t.i.d. in neuroses; one 10-mg. tablet t.i.d. in psychoses.

a superior psychochemical
for the management of both major and minor emotional disturbances

SPONTIN IN SERIOUS

A Special Report from Abbott
to the Medical Profession
on a Year's Clinical Experience
with SPONTIN®
(Ristocetin, Abbott)

In a Spanish province, a patient lay dying of endocarditis. A short wave radio appeal for SPONTIN was intercepted by a Baltimore physician. The antibiotic was immediately flown to this faraway land, and 10 days later—the patient had recovered.

In Chicago, a moribund patient had been administered 18 combinations of 10 different antibiotics without success. Involved was a hospital-acquired staphylococcal pneumonia—plus complications. SPONTIN was substituted and the patient lived.

A five-week-old infant was critically ill with staphylococcal enteritis. Treatment failures included erythromycin and chloramphenicol. Three days of SPONTIN saved this life. The list is long and impressive and it grows daily.

Recently, a study[1] was made of serious and resistant staphylococcal infections reported to Abbott Laboratories. Many of these cases had serious complicating diseases—many were moribund, or almost so, at the time SPONTIN was started. Yet, out of the 160 staphylococcal cases studied, 93 were reported cured and 38 improved after the administration of SPONTIN.

Out of the total of 251 patients with severe infections caused by gram-positive or mixed organisms, 149 were reported cured and 53 others improved. And the record for pediatric practice was every bit as good.

Additionally, SPONTIN continues to exhibit exceptional bactericidal activity against coccal infections[2]. And, according to another study, SPONTIN provides successful short-term therapy in endocarditis[3].

901086

Only last October, at the Antibiotics Symposium in Washington, D. C., a panel of six leading antibiotic experts placed SPONTIN at the top of all other commercially-available antibiotics for treating serious staphylococcal infections. Also, six papers—all dealing with the effectiveness of ristocetin (SPONTIN®) in treating staphylococcal infections—were presented at the Symposium.

One of the most encouraging aspects of the year's literature on SPONTIN is the increasing testimony to its safety. As the months have passed and cases have accumulated by the hundreds, it has become apparent that careful attention to dosage recommendations has practically eliminated toxicity and side effects as serious obstacles to therapy. Also, recent improvements have been made in the manufacture of SPONTIN; the drug is now made from pure crystals.

A recent report[4] in the Journal of the American Medical Association concluded, "It is our opinion that, if proper precautions are observed, ristocetin is a [well tolerated] and potent agent to employ in the treatment of staphylococcal infections." And in another study, after successfully treating 28 patients with a variety of staphylococcal infections, the authors reported[5], "No serious complications were noted."

Few more dramatic records have been written in such a short space of time. SPONTIN has proved itself to be a good answer, perhaps the best answer at present, to the resistant staphylococcal problem—and of real value in other serious coccal infections. It may well be your answer when you're confronted with a serious infection.

Abbott

STAPHYLOCOCCAL INFECTIONS

Excerpts from Reports Read at the Antibiotics Symposium

Spontin In Treating Severe Respiratory Infections —"In 13 of 20 patients the results were excellent, with clinical response being evident within one to four days after institution of therapy. In three additional patients, there was some degree of improvement in pneumonic processes superimposed on tuberculosis in two cases and on pulmonary neoplasm in one. In all other cases, serious antecedent pathology undoubtedly influenced the negative or equivocal response to ristocetin therapy.[6]"

Spontin In Treating Staphylococcal Infections—After successfully treating 28 patients, the authors wrote, "Ristocetin or Spontin has proved to be bactericidal and bacteriostatic, particularly for the *Staphylococcus aureus*, which is often resistant to many other antibiotics.[5]"

Spontin In Treating Seven Difficult Cases – "Ristocetin has produced excellent results in eradicating, mitigating or preventing infection in seven selected difficult cases. Six of the seven cases involved *Staphylococcus aureus* which did not respond to chemotherapy with other antibiotics.[7]"

Spontin Blood Levels In Children – "Ristocetin was administered as a single intravenous injection of 12.5 milligrams per kilogram. This resulted in serum levels ranging from 1.3 to 10.6 mcg. after two hours with a gradual fall to a level of 0.7 mcg. per cubic centimeter or less after 12 hours.[8]"

Spontin In Treating Staphylococcal Pneumonia —"Ristocetin was used in the treatment of 24 patients with staphylococcal pneumonia, 17 of whom had failed to respond to previously administered antibiotics. Complete clearing of pneumonitis was obtained in 16 patients and significant improvement occurred in two others. Two patients died of pneumonia; four others succumbed to other lethal diseases.[9]"

Spontin In Treating Children and Adults – "Ristocetin completely controlled severe staphylococcal infections in 11 adults and six children who received adequate therapy.[10]"

Minnesota Blue Cross—Blue Shield

Dr. Edwin J. Simons, the Executive Director of Minnesota Blue Shield, unexpectedly passed away on December 11, 1958. In his death the medical profession lost a highly regarded member, Blue Shield lost a strong proponent, and the people of Minnesota lost an exemplary citizen dedicated to serving mankind.

Dr. Simons joined Blue Shield as medical director in 1950. On January 1, 1954, he accepted the position of executive director, but continued also to carry out the duties of the medical director. Under his leadership the Blue Shield Plan experienced its greatest growth and progress. The number of participant subscribers increased tremendously. The scope of coverage was greatly broadened consistent with advances in the science of medicine. The reserve structure of the Plan was strengthened, thereby assuring the public and the profession of an economically sound organization, yet the cost of coverage was kept sufficiently low as to be within the financial reach of any segment of Minnesota's population.

Dr. Simons was always deeply concerned with maintaining the free choice of physician and the unfettered relationship which should exist between the doctor and patient. He firmly believed that an effective Blue Shield program would help assure free choice of physician and close doctor and patient relationships. Toward these ends he directed Blue Shield operations.

Prior to joining Blue Shield Dr. Simons practiced general medicine in Swanville, Minnesota, for approximately 25 years. He also served as medical director of the Minnesota Division of Social Welfare for five years.

Dr. Simons was well known by Minnesota doctors, having been a member of the Upper Mississippi Medical Society and the Minnesota State Medical Association. He served the Upper Mississippi Medical Society as president in 1935 and the Minnesota State Medical Association as president in 1946.

Dr. Simons' associates in Blue Cross and Blue Shield are grateful for having had the opportunity of knowing and working with him. His example, devotion and knowledge of Blue Shield affairs served as an inspiration to everyone associated with the Plan.

* * *

The most recent figures compiled by Minnesota Blue Cross indicate that the number of subscribers receiving hospital care through their Blue Cross coverage totaled 215,729 during 1958.

This represents subscriber usage of 504 cases paid per year per 1,000 contracts protected, an increase of nearly 5 per cent over the rate of usage experienced during the preceding year.

During the year 1958, Blue Cross subscribers received hospital care benefits in excess of $34,000,000. This represents an increase of 18 per cent over the benefits provided subscribers during the preceding year.

Days of hospital care provided subscribers during 1958 totaled 1,332,580 which represents over three days of hospital care for every Blue Cross contract in effect during the year.

In Memoriam

DON F. FITZGERALD

Dr. Don F. FitzGerald died December 8, 1958. He was ninety-two years of age at the time of his death.

The deceased received his early schooling in New Orleans, Louisiana, New Haven, Connecticut, Albany and Brooklyn, New York. He came to Minneapolis at the age of eighteen and became a correspondence clerk at the Nicollet National Bank, later absorbed by the First National Bank.

He was a Spanish-American War Veteran and served with the Thirteenth Regiment of Minnesota in the Philippines in 1898. Upon returning in 1899, he enrolled in the University of Minnesota Medical School where he earned his medical degree, a graduate of the class of 1903. In 1953, Dr. FitzGerald was granted a membership in the Fifty-year Club of the Minnesota State Medical Association, and he was a member of the Hennepin County Medical Society. In 1953, also, the University of Minnesota designated him as Graduate Emeritus.

Dr. FitzGerald is survived by his wife, Isabelle, and three sons, Don, Santa Barbara, California; Norman, Corona del Mar, California; and Gerald, West Caldwell, New Jersey.

JOHN H. HIGGINS

Dr. John H. Higgins, a Minneapolis practicing physician for more than fifty years, died December 31, 1958. He was eighty years of age at the time of his death. Born in Milwaukee, Wisconsin, Dr. Higgins had lived in Minneapolis for sixty years.

He was a graduate from the University of Minnesota Medical School in 1903 and practiced medicine until the time of his retirement three years ago.

Dr. Higgins was a member of the staff of Asbury Hospital, a member of the Hennepin County Medical Society, the Minnesota State Medical Association, and the American Medical Association. He was also a member of Workmen's Lodge, Woodmen and Odd Fellows.

Surviving are his wife, Grace L.; a daughter, Mrs. William H. Mahnke; a son, John C.; three grandchildren, and a sister, Marguerite I., all of Minneapolis.

FRANCIS J. SAVAGE

Dr. Francis J. Savage, a long-time St. Paul physician and former president of the Minnesota State Medical Association, died of a heart attack on January 16, 1959. He was eighty-three years at the time of his death.

The deceased, for many years, was a surgeon for the Great Northern Railroad. He was active in the private practice of medicine until the time of his retirement in May, 1958.

In 1954, he received the distinguished service award of the Minnesota State Medical Association. He served as state president in 1934 and was a former member of the council and delegate to the American Medical Association.

In 1951, Dr. Savage became a member of the Fifty-year Club.

A native of Stockbridge, Massachusetts, Dr. Savage received his medical degree from the University of Minnesota in 1901. He interned at Minneapolis General Hospital and served eighteen months as an Army Captain during World War I. In 1927, he served as president of the Ramsey County Medical Society.

He is survived by his wife, Mary; a daughter, Mrs. Townsend B. Pettit, Jr., of Garden City, Long Island, and two grandchildren.

ISAAC F. SEELEY

Dr. Isaac F. Seeley, Northfield physician for forty-two years, died January 3, 1959, at his home in Tucson, Arizona. He was seventy-eight years old at the time of his death.

The former Northfield physician retired in 1950 to his Arizona home after completing forty-six years in the practice of medicine.

Dr. Seeley was born in 1881 in the pioneer Minnesota village of Cordova in Le Sueur County. His father, John S. Seeley, was a physician in Cordova before moving to Faribault. In Faribault, the senior physician served actively in the practice of medicine for forty-five years.

Dr. Isaac Seeley received his medical degree from the University of Iowa in 1904. Following the completion of his education, he practiced for about one year in Elysian. Next, he accepted a position as physician with construction companies building the Milwaukee Railroad lines through the Rocky Mountains. He continued in this phase of his career for approximately two years. He served for many years as health officer for the city of Northfield.

He was a member of the Rice County Medical Society, the Minnesota State Medical Association and the American Association of Railroad Surgeons. A member of the Masonic Fraternity, Dr. Seeley had been presiding officer in all the local bodies, including Social Lodge, No. 48, A.F. & A.M. of Northfield and Faribault Commandery, Knights Templar. He was a member of the Ozman Temple of the Shrine, in St. Paul. He served as Grand Master of the Grand Council of Minnesota and was a keenly interested participant in Masonic work for many years.

Surviving Dr. Seeley are his wife, Alice; his son, Sanford; and two step-daughters, Mrs. Robert Epstein (Audrey) of Tucson, and Mrs. James Young (Patricia) of Albuquerque, New Mexico.

maintenance therapy is still fundamental treatment

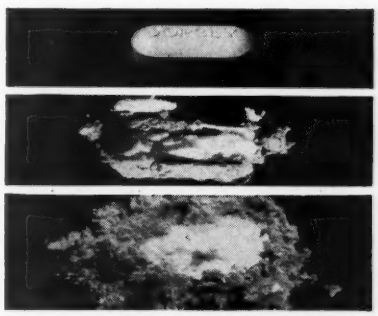
Sound, conservative therapy with salicylates has been consistently reaffirmed as basic, long-term maintenance therapy in the arthritides.[1,2,3]

Buffered Pabirin provides superior maintenance therapy. It epitomizes fundamental long-term basic therapy since it can be given month after month without serious complications and with minimal problems to patient and doctor alike.

Buffered Pabirin is formulated to provide high and sustained salicylate blood levels. Each tablet consists of an outer layer containing a buffer (aluminum hydroxide), para-aminobenzoic acid, and ascorbic acid; a core of acetylsalicylic acid.

In the stomach, the outer layer quickly releases the buffer, which protects against nausea, dyspepsia and other gastrointestinal symptoms so frequently encountered with salicylates alone. The core of Buffered Pabirin then disintegrates rapidly, permitting rapid absorption of the acetylsalicylic acid for faster pain relief.

Report of Joint Committee, Medical Research Council & Nuffield Foundation, Treatment of Rheumatoid Arthritis, British Medical Journal (April 13) 1957. 3. Friend, D. G.: New England J. Med. 257:278 (Aug.) 1957.



Buffered Pabirin® *Tablets*

Each tablet contains:

Acetylsalicylic acid (5 gr.)	300 mg.
Para-aminobenzoic acid (5 gr.)	300 mg.
Ascorbic acid	50 mg.
Dried aluminum hydroxide gel	100 mg.

All Buffered Pabirin is sodium- and potassium-free.

Dosage: Two or three tablets 3 or 4 times daily.

Photographs show 2-stage Tandem Release disintegration.

VENEREAL DISEASES SYMPOSIUM SCHEDULED

The Tenth Annual Symposium on Recent Advances in the Study of Venereal Diseases will be held April 27-28, 1959, at Johns Hopkins University, Baltimore, Maryland. The sessions are open to all physicians and workers in allied fields who are interested in the venereal diseases.

This Symposium, sponsored jointly by the American Venereal Disease Association and the Public Health Service, will precede a Venereal Disease Seminar for public health personnel of fourteen eastern states, beginning April 29.

Anyone wishing to present a scientific paper on a subject related to venereal diseases should mail preliminary abstracts to Dr. William J. Brown, chairman of the Program Committee, by February 15. Address: Communicable Disease Center, Public Health Service, 50 Seventh Street, N.E., Atlanta 23, Georgia. The committee will meet in mid-February to select papers to be presented.

Authors of accepted papers will be notified before March 15.

HEARING SOCIETY ANNOUNCES AWARD COMPETITION OPENING

Competition for the 1959 Kenfield Memorial Scholarship, awarded annually by the American Hearing Society to a prospective teacher of lipreading, will open February 1.

Winner of the scholarship will be entitled to take a course in "Methods and Practice in Teaching Lipreading" from any school or university in the United States offering a course acceptable to the teachers committee. A requirement is that the scholarship be used within one year after date of award.

Rules for competition state that a satisfactory applicant shall be a "well-adjusted individual with a pleasing personality, legible lips, good speech, and voice, and no unpleasant mannerisms." Graduation from college, with a major in education, psychology, and/or speech is a requirement.

Application blanks may be obtained by writing to Miss Ruth Bartlett, chairman of the society's teachers committee, 432 So. Curson Ave., E., Los Angeles 36. Completed applications and recommendations must reach Miss Bartlett by April 1.

RESEARCH IN PREVENTION OF BLINDNESS

The Research Committee of the National Society for the Prevention of Blindness invites requests for research grants in 1959. Funds are available for projects that may contribute to basic understanding of eye function and pathology, or that may improve methods of diagnosis, treatment or prevention of blinding eye diseases. Grants will be made this spring for requests received prior to May 1, and inquiries can be addressed to Research Committee, National Society for the prevention of Blindness, 1790 Broadway, New York 19, New York.

MAYO CLINIC REVIEWS DATES SET

Staff members of the Mayo Clinic and the Mayo Foundation for Medical Education and Research will present again this year a three-day program of lectures and discussions on problems of current interest in general medicine and surgery, April 13, 14, 15, 1959.

Up to twenty-one hours of Category I credit may be

for depression

▲Deprol▲†

Clinically confirmed in over 2,500 documented case histories[1,2]

CONFIRMED EFFICACY

Deprol ► acts promptly to control depression *without* stimulation

► restores natural sleep

► reduces depressive rumination and crying

DOCUMENTED SAFETY

Deprol is unlike amine-oxidase inhibitors

► does not adversely affect blood pressure or sexual function

► causes no excessive elation

► produces no liver toxicity

► does not interfere with other drug therapies

Deprol is unlike central nervous stimulants

► does not cause insomnia

► produces no amphetamine-like jitteriness

► does not depress appetite

► has no depression-producing aftereffects

► can be used freely in hypertension and in unstable personalities

Dosage: Usual starting dose is 1 tablet q.i.d. When necessary, this dose may be gradually increased up to 3 tablets q.i.d.

Composition: Each tablet contains 400 mg. meprobamate and 1 mg. 2-diethylaminoethyl benzilate hydrochloride (benactyzine HCl).

Supplied: Bottles of 50 scored tablets.

1. Alexander, L.: Chemotherapy of depression—Use of meprobamate combined with benactyzine (2-diethylaminoethyl benzilate) hydrochloride. J.A.M.A. 166:1019, March 1, 1958. 2. Current personal communications; in the files of Wallace Laboratories.

LETTERS
TO THE MEDICAL DIRECTOR

Dear Doctor:

Rauvera* was used on five patients with essensential hypertension varying from moderate to severe. The highest blood pressure was 220/130 and the lowest 180/105.

All patients have shown a consistent response to the drug and the continuation therapy has effected a good control so far . . . approximately two to three months. In four patients systolic blood pressure was reduced from 20 to 50 mm. Hg and the diastolic from 10 to 15 mm. One patient, who had a pressure of 220/130 has had a phenomenal response, and I brought the systolic down to 165 and the diastolic to 95.

M. D., Wisconsin

Dear Doctor:

Rauvera has produced satisfactory reductions of blood pressure in every hypertensive case in which I have used it.

M. D., Colorado

Dear Doctor:

Rauvera tabs are my choice for hypertension over 170 . . . they give me the best results.

M. D., Texas

Comment: *It is interesting to note that no adverse side effects were reported in connection with Rauvera's effective antihypertensive action.*

*Rauvera contains 1 mg. alseroxylon (purified Rauwolfia serpentina alkaloid), 3 mg. alkavervir (Veratrum viride fraction) in each scored tablet.

obtained by American Academy of General Practice members who attend.

There are no fees for this program.

The number of physicians who can be accommodated is necessarily limited. Those wishing to attend should communicate with the Clinical Reviews Committee, Mayo Clinic, Rochester, Minnesota.

RESULTS OF COUNTY MEDICAL SOCIETY ELECTIONS

Blue Earth County

Officers for the present year were elected at a dinner meeting of the Blue Earth County Medical Society held at the Century Club in Mankato. They are Dr. G. E. Penn, president; Dr. J. T. Olive, vice president; and Dr. R. A. Sanford, secretary-treasurer. Terms are for one year. Outgoing officers are Dr. J. C. Von Drasek, president; Dr. R. D. Roth, vice president; and Dr. D. B. Swenson, secretary-treasurer.

Clay-Becker Counties

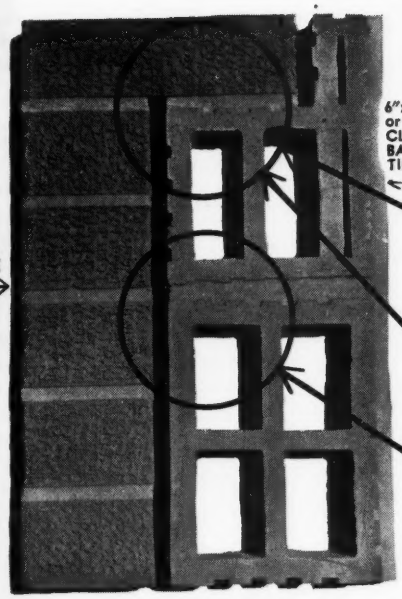
The Clay-Becker Medical Society held its annual meeting in the Hawley Lutheran Church recently.

Business of the evening included the election of officers and committee members. Dr. Arvin Houglum of Lake Park was named to a committee of public relations along with Dr. Arnold Larson, Detroit Lakes, Dr. O. H. Johnson and Dr. James Lucan, both of Moorhead.

Dr. V. J. Carlson of Moorhead was elected president with Dr. Virgil Larson, Detroit Lakes, president-elect; Dr. Carl Siminson, Barnesville, vice president; Dr. James Oliver, Moorhead, secretary-treasurer; and Dr. J. B. Rutledge, Detroit Lakes, historian.

Park Region

The Park Region District and County Medical Society held its annual meeting at the Ranch House in Fergus Falls recently. Dr. Lester R. Parson, president presided, and the scientific program was presented by Dr. Chen En Lu and Dr. Richard Ness of Fergus Falls, who spoke on subjects in their respective fields.



The following officers were elected for the year of 1959: Dr. Henry A. Korda, Pelican Rapids, president; Dr. David J. Sanderson, Fergus Falls, president-elect; Dr. Charles W. Lewis, Henning, vice president; Dr. Peter M. Geiser, Alexandria, secretary; Dr. Carl J. Lund, Fergus Falls, treasurer; Dr. Edwin J. Tanquist, Alexandria, Dr. V. A. Doms, Battle Lake, executive committee; Dr. Glen J. Mouritsen, Fergus Falls, delegate; Dr. Norman H. Baker, Fergus Falls, alternate delegate.

Red River Valley

Dr. Hubert D. Clapp, Crookston, was elected president of the Red River Valley Medical Society when the group held its annual meeting recently at Sidney's Cafe in Crookston. M. D. Tyson, civil defense coordinator

Be SAFE and SURE with Clay Tile

FOR 10" WALL

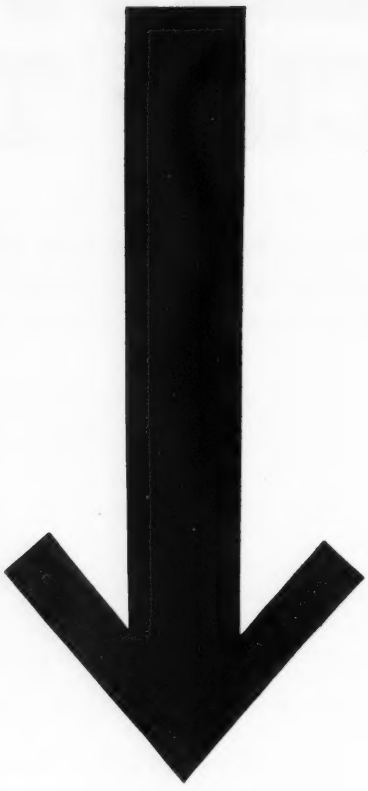
(6" Backup is load bearing, passes 2 hour fire test, saves two inches of space.)

FOR 12" WALL

HERE'S WHY IT PAYS TO SPECIFY DENISON STRUCTURAL CLAY TILE BACKUP FROM MASON CITY BRICK AND TILE CO.

1. Header provides positive bond with face brick — eliminates movement in the wall, thus reducing cracking, expansion and contraction problems.
2. All tile plastering surface.
3. Vertical alignment of shells and webs provides maximum compressive strength.
4. No through mortar joints to conduct heat or moisture through the wall. Clay tile is free from soluble salts which can contribute to efflorescence.
5. Uniform coursing heights for exposed interiors.
6. Available in textured or scraped face for exposed interiors. Write for literature.

You *can* be sure when you specify Denison Clay Tile backup — for you know it will perform perfectly, you know it will assure long life and complete satisfaction in the building you design. You need not run the risk of damp, cold buildings, high maintenance and heating costs, cracked walls and hard-to-clean interiors. Specify Denison Clay Backup Tile and you know you're right!



NEW Have you seen the NEW Ottumwa Buff Velour Face Tile? If not — you're in for a pleasant surprise. You'll find Buff Velour the answer to many design problems involving exposed interiors and exteriors of tile. It's most attractive! Write for full information.

RESULTS OF COUNTY MEDICAL SOCIETY ELECTIONS

(Continued from page A-54)

of the State Department of Health, discussed the new concepts of Civil Defense and Disaster Control. Tom Cook, executive secretary, Hennepin County Medical Society, Minneapolis, talked on the problems of public relations for physicians.

Other officers elected to serve with Dr. Clapp were: Dr. Clifford J. Stadum, Twin Valley, vice president; Dr. Russell O. Sather, Crookston, secretary-treasurer; Dr. Edgar L. Sather, Fosston, censor; Dr. Lester N. Dale, Red Lake Falls, delegate to the Minnesota Medical Association House of Delegates with Dr. Eskil Erickson, Halstad, alternate.

St. Louis County

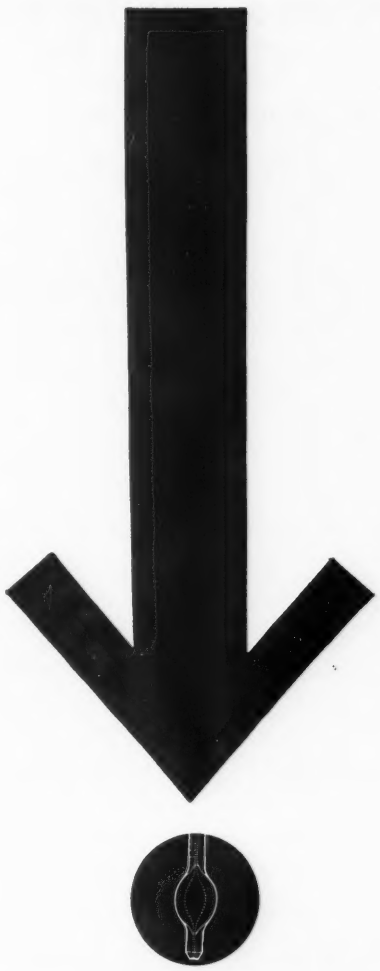
Dr. John H. Peterson, Duluth, has been elected president-elect of the St. Louis County Medical Society. Results of the society election were announced at the organization's annual dinner-dance in the Kitchi Gammi club. His election opponent was Dr. W. C. Martin. Peterson takes office in 1960. Dr. John C. Feuling, incumbent president, will be succeeded in 1959 by Richard Barton, M.D.

Dr. Herbert O. Hoff was elected vice president. New secretary-treasurer will be Dr. Robert J. Goldish, succeeding Dr. R. O. Bergan. Dr. Bergan was named to a three-year term on the advisory committee.

Winona County

Dr. L. J. Wilson, Winona, has been elected president of the newly reorganized Winona County Medical Society.

He was one of five officers elected at the society's annual meeting at which a new constitution and by-laws—establishing for the first time a board of directors—were adopted.



One of the principal objectives of the formation of a five-member board was to develop better communications.

Up to the present time the society has met in quarterly sessions but the new board of directors may be called together at any time the president feels that there is a matter calling for attention of the group.

The annual meeting was held January 7 at Hotel Winona and was attended by members of the society and their wives.

Dr. Wilson succeeds Dr. Carl Heise as president. Other officers of the society are: Dr. Warren W. Haesly, vice president; Dr. Charles W. Rogers, secretary-treasurer; Dr. G. L. Loomis, director for one year, and Dr. Paul Heise, director for two years.

Dr. L. I. Younger was named delegate to the Minnesota State Medical Association and Dr. Howard Satterlee, Lewiston, alternate delegate.

FOR IRON DEFICIENCY ANEMIAS
THE ORIGINAL HEMATONIC
WITH "INSURED IRON"

GLOBOTRIN®
patch

- insured for therapeutic effect by inclusion of vitamin and enzyme metabolites
- insured against side effects by better tolerated ferrous lactate and methylcellulose to maintain "bowel equilibrium"
- particularly valuable for pregnant and geriatric patients
- easy to take — in small, thinly coated tablets

EACH RED, COATED TABLET CONTAINS:

Ferrous lactate (supplying 37 mg. elemental iron)	195 mg. (3 gr.)
Vitamin B_{12} crystalline with intrinsic factor concentrate	0.5 U.S.P. unit*
Thiamine hydrochloride	2.5 mg.
Ascorbic acid	50 mg.
Betaine hydrochloride	60 mg.
Methylcellulose	32.5 mg.

*Potency established before formulation.

Supplied in bottles of 60 tablets.

70 YEARS OF SERVICE TO THE MEDICAL PROFESSION

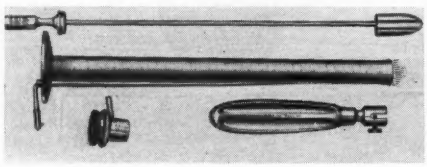
Woman's Auxiliary

BLUE EARTH MEDICAL AUXILIARY TO SEND DRUGS TO BAHAMAS

Members of the Blue Earth County Medical Auxiliary, are undertaking a unique project which will result in a supply of free drugs to people of the Bahama Islands.

The Medical Auxiliary is collecting the drug samples, sent to their husbands by various pharmaceutical firms and not ordinarily utilized, and sending them to the Nassau County Health Department in the Bahama Islands for distribution by doctors to Bahamians.

The drug supplies are turned over by the auxiliary to Mrs. Eva Quiram of Waterville, formerly with the Health Service in Nassau, who sends the drugs there.



Another collection of drug supplies will be made by the auxiliary in the spring. The collecting is done with the consent of the Blue Earth County Medical group.

HENNEPIN COUNTY AUXILIARY ACTIVITIES

On Friday, January 16, the Woman's Auxiliary to the Hennepin County Medical Society held its area coffee parties. The prime objective of these parties is to afford the individual member an opportunity to become better acquainted with the other members from her own area, thus consolidating the membership of the auxiliary as a whole.

62-64 East 5th Street
St. Paul 1, Minnesota

Mrs. Conrad Holmberg, Civil Defense and Safety Chairman, had available for distribution information regarding the most recent developments in civil defense.

The following women graciously opened their homes for the parties, and the auxiliary wishes to express its appreciation to them:

Mrs. Rolf L. Andreassen, 3829-19th Ave. So.; Mrs. Aaron Friedell, 2700 Chowen Ave. So.; Mrs. Nathaniel H. Lufkin, 330 E. Diamond Lake Road; Mrs. John W. MacDonald, 6633 Parkwood Road; Mrs. B. D. Mitchell, 641 So. Westwood Drive; Mrs. Mancel Mitchell, 4613 Browndale; Mrs. Malvin Nydahl, Willow Creek, Hopkins; Mrs. L. J. Petit, 6305 Russell Ave. So.; Mrs. Frederick H. K. Schaaf, 1238 W. Minnehaha Parkway; Mrs. Lewis Sher, 3941 Washburn Ave. So.; and Mrs. Wesley Spink, 1916 E. River Terrace.

Mrs. Emerson E. Hoppes, telephone and area chairman, was in charge of general arrangements.

* * *

Members of the Woman's Auxiliary to the Hennepin County Medical Society were extended invitations by the Hennepin County Dental Auxiliary to be their guests at a tea and joint meeting on February 9 at the Prudential Life Insurance Building.

The program was highlighted by discussion on the topic "How peoples of the World could get along Together in Peace." Taking part in this panel were: The Reverend Morris G. Robinson of Grace Presbyterian Church who discussed the topic from the religious aspect, The Rabbi Stanley Rabinowitz from Adath Jeshurun Synagogue who discussed the political aspect and Mr. Graham Hovey of the Minneapolis *Star* and *Tribune* who discussed the economic aspect. Mrs. D. R. Clark was the moderator.

RAMSEY COUNTY MEDICAL AUXILIARY SHOWS CANCER FILM

"The Other City," an American Cancer Society film, was shown at a meeting of the Woman's Auxiliary to the Ramsey County Medical Society in Coleman's Highland Village restaurant. At the meeting, Mrs. Louis L. Friedman, auxiliary representative to the Ramsey County Tuberculosis and Health Association presented the annual awards to high school essay contest winners. Mrs. Wallace A. Gleason is auxiliary representative to the Cancer Society.

While the tuberculosis problem in this country may be shrinking somewhat, the total field of lung diseases is enlarging with the aging of the population, reports the National Tuberculosis Association.—*Christmas Seal Health News.*

AN EXPERIMENT IN MEDICAL NOMENCLATURE INTRODUCING THE TERM:

"cell examination for uterine cancer"

The exfoliative cytological examination is called by some doctors the *cytologic cervical test*—by others the *"Pap" smear test.* In urging all women to have this test annually, we are calling it the *cell examination for uterine cancer.*

Here are our reasons:

Cytologic cervical test is a term which seems complicated to many women.

"Pap" smear test is simple, but women we have talked to find the word "smear" unpleasant and disturbing, and it may add to their anxieties about pelvic examinations.

Public relations advisors say that broadcasters and editors will dislike "smear"— and TV, radio and the press will be essential to the success of this educational project.

We have considered other terms but have at last agreed on *cell examination for uterine cancer* as the term which simply and accurately describes the keystone of this vitally important program.

This test can help save thousands of women each year. In many parts of the country it is becoming widely accepted as a part of a routine checkup. As fast as county medical societies approve, our local Units will urge women to go to their physicians annually for a *cell examination for uterine cancer.*

AMERICAN CANCER SOCIETY

(Continued from page A-62)

Newly returned from a 35,000-mile global trip as a lecturer for the International College of Surgeons, **Dr. Winchell McK. Craig** has left on a trip to Cairo, Egypt, by way of London and Naples. Dr. Craig will make the trip as a member of an official delegation named to represent the United States Navy at the tenth anniversary celebration of the founding of the Naval Medical Research Unit in Cairo. Established for the study of tropical diseases, the unit is maintained by the Navy at Cairo and staffed by medical officers.

On his recent tour with a delegation representing the International College of Surgeons, he was in Hawaii, Japan, Hong Kong, the Philippines, Thailand, India, Egypt, Turkey, Greece, Italy and Spain. He was one of six lecturers in a 28-member group, which met with local chapters of the international organization. His trip included lectures to medical students, schools and societies. On his forthcoming trip, Dr. Craig will appear at a meeting of the Medical Society of Egypt. The meeting is arranged by the Egyptian Ministry of Health.

* * *

A new associate of the Chisago Lakes Clinic is **Dr. William H. Thomas**, Howard Lake.

* * *

Dr. J. J. Heimark, Mankato, was elected president of the Immanuel Hospital medical staff at a recent meeting of the staff. He will serve through 1959. Other new officers elected were **Dr. E. E. Heller**, vice president; **Dr. J. B. Lund**, secretary-treasurer; and **Drs. M. W. Dobson, H. J. Smith and H. R. Snider** to the executive committee.

* * *

Willmar's oldest practicing physician, **Dr. Jno. C. Jacobs**, has retired after fifty-two years in the practice of medicine in that area. He is eighty years old.

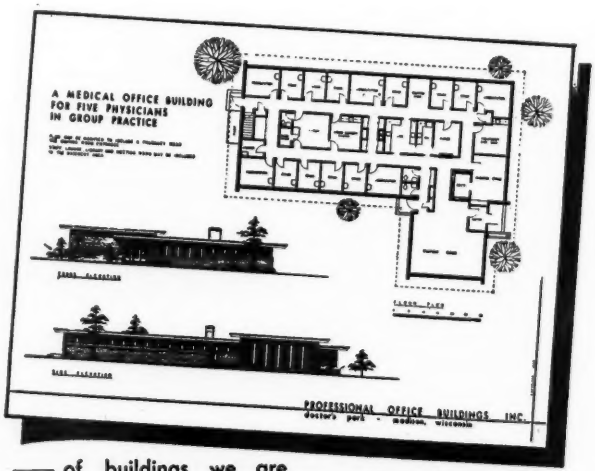
* * *

Dr. Leo Furr has become associated with **Drs. H. P. Hinderaker** and **D. G. Alton**, Bird Island. Dr. Alton will leave Bird Island the first of March to join a three-man medical group in St. Paul.

* * *

Dr. Victor Johnson, director of the Mayo Foundation, attended the 55th annual Congress on Medical Education and Licensure, February 7-10, in Chicago.

* * *



Dr. Cecil J. Watson, head of the University of Minnesota Medical School's department of medicine, has received a "distinguished service" award from *Modern Medicine*, national medical publication, it has been announced. In the citation, Dr. Watson was specifically honored for "his additions to clinical knowledge of liver function and the clarification of porphyrin metabolism." Porphyrins constitute a key group of compounds for the existence of life. Dr. Watson has been active in this research field since 1931.

STOP

running noses

and open stuffed noses orally

with TRIAMINIC, the oral nasal decongestant

- in nasal and paranasal congestion
- in sinusitis
- in postnasal drip
- in allergic reactions of the upper respiratory tract

safer and more effective than topical medication

- reaches *all* respiratory membranes systemically
- avoids "nose drop addiction"
- presents no problem of rebound congestion
- provides longer-lasting relief

Relief with Triaminic is prompt and prolonged because of this special timed-release action . . . beneficial effect starts in minutes, lasts for hours.

first—the outer layer dissolves within minutes to produce 3 to 4 hours of relief

then—the inner core disintegrates to give 3 to 4 more hours of relief

Each* TRIAMINIC *Tablet provides:

Phenylpropanolamine HCl	50 mg.
Pheniramine maleate	25 mg.
Pyrilamine maleate	25 mg.

One-half of this formula is in the outer layer, the other half is in the core.

Dosage: One tablet in the morning, mid-afternoon and in the evening, if needed.

Triaminic®

Also available: For the occasional patient who requires only half dosage: timed-release TRIAMINIC JUVELETS. Each Juvelet is equivalent to ½ of a Triaminic Tablet.

For those patients who prefer liquid medication: TRIAMINIC SYRUP. Each 5 ml. tsp. of this palatable syrup is equivalent to ¼ of a Triaminic Tablet.

A workhorse "mycin" for common infections

respiratory infections

prompt, high blood levels

consistently reliable and reproducible blood levels

minimal adverse reactions

With well-tolerated CYCLAMYCIN, you will find it possible to control many common infections rapidly and to do so with remarkable freedom from untoward reactions. CYCLAMYCIN is indicated in numerous bacterial invasions of the respiratory system—lobar pneumonia, bronchopneumonia, tracheitis, bronchitis, and other acute infections. It has been proved effective against a wide range of organisms, such as pneumococci, H. influenzae, streptococci, and many strains of staphylococci, including some resistant to other "mycins." Supplied as Capsules, 125 and 250 mg., vials of 36; Oral Suspension, 125 mg. per 5-cc. teaspoonful, bottles of 2 fl. oz.

Until the discovery of DECADRON* by MERCK SHARP & DOHME, when your diabetic patients were also in need of corticosteroid treatment, you were often faced with a difficult therapeutic dilemma. Diabetes mellitus was a recognized contraindication to the use of corticosteroids, since they not only aggravated the existing diabetic symptoms, but often precipitated latent diabetes.

NOW EVEN many diabetic patients may have THE FULL BENEFITS OF CORTICOSTEROID THERAPY

DECADRON—the new and most potent of all anti-inflammatory corticosteroids—is remarkable for its **virtual absence of diabetogenic effect** in therapeutic doses.

Decadron*

DEXAMETHASONE

to treat more patients more effectively

In clinical trials with some 1,500 patients glycosuria was noted in only two, transitory glycosuria in another two, and flattening of the glucose tolerance curve in one. There were no instances of aggravation of existing diabetes, no increase in insulin requirements. Patients whose diabetes was severely aggravated on prednisolone showed good tolerance when transferred to DECADRON.

MORE patients can be treated with DECADRON than with other corticosteroids, because in addition to being practically free of diabetogenic activity, therapy with DECADRON is also practically free of sodium retention, potassium depletion, hypertension, edema and psychic disturbances. Cushingoid effects are fewer and milder. DECADRON has not caused any new or "peculiar" reactions, and has produced neither euphoria nor depression, but helps restore a "natural" sense of well-being.

*DECADRON is a trademark of Merck & Co., Inc., ©1958 Merck & Co., Inc.

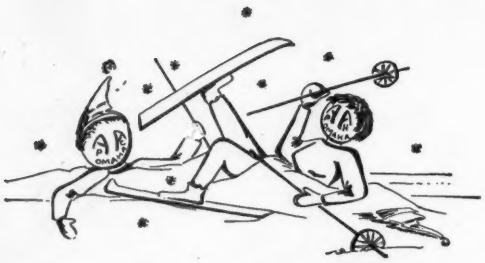
VIRAL AND RICKETTSIAL INFECTIONS OF MAN. Third Edition. Edited by Thomas M. Rivers, M.D., Member Emeritus, The Rockefeller Institute; Vice President, Medical Affairs, The National Foundation; and Frank L. Horsfall, Jr., M.D., Vice President for Clinical Studies, Physician-in-Chief to the Hospital, Rockefeller Institute. 967 pages. Illus. Price $8.50 cloth. Philadelphia: J. B. Lippincott Co., 1959.

PRACTICAL LEADS TO PUZZLING DIAGNOSES. By Walter C. Alvarez, M.D., D.Sc. 490 pages. Price $9.00. Philadelphia: J. B. Lippincott Co., 1958.

Dr. Alvarez anticipates the criticism that may be directed towards his newest book because of the informal nature in which he presents his material.



It is the informal method in presenting the material that makes this book attractive. His wide clinical experience and understanding of the functionally ill patient is evident throughout this book. His suggestions concerning diagnosis and his weight of the handling of these patients makes this book most valuable. This book may be recommended to all physicians for its pleasant style and its ease of reading as well as for its valuable suggestions in the diagnosis and handling of this type of patient.

JOHN F. BRIGGS, M.D.

THE CARE OF THE GERIATRIC PATIENT. Edited by E. V. Cowdry, Ph.D., Sc.D. (Honorary). 438 pages. Price, $8.00. St. Louis: The C. V. Mosby Company, 1958.

The impressive list of contributors to this volume emphasizes the importance of this expanding field of medicine, geriatrics. Mr. Bernard M. Baruch rightly has stated that the recent prolongation of life has more implications now and in the future than most any other advancement of knowledge in a field. This book carries out the command of Drs. Piersol and Bortz who some

Protection against loss of income from accident & sickness as well as hospital expense benefits for you and all your eligible dependents.

years ago said, "It is for science not only to add years to life, but more important, to add life to years."

The field of geriatrics may become a full-fledged specialty in the future. The training is hard to receive at this time and often physicians are called upon to expand their knowledge to include the present fundamental principles in this new field of caring for old people. These fundamentals are included in the text edited by Dr. Cowdry.

The section on cancer detection is built around our own Minnesota cancer detection program. This reflects one of the many facets of the geriatric problem which is moving forward rapidly in our own state.

A section stressing the importance of weight reduction in the obese geriatric patient is too short for its relative importance in patient care. A checklist for laboratory tests to be carried out at various intervals is valuable to the busy practitioner and might well be duplicated and placed on the chart of every patient past fifty years of age.

The mental aspects of the elderly patient are amply discussed. With the increasing number of elderly patients left in hospitals, a plea is made to indoctrinate the public and the medical profession with the concept that many older patients can be treated and sent home in a relatively short period of time.

A section of the textbook on differences in surgical techniques and anesthetics to be used in geriatric patients is helpful, to say the least.

DONALD W. KOZA, M.D.

A trust service for the living

With the establishment of its new Trust Department, Fidelity brings with it a fresh concept of the services such a department can render. Times *have* changed. Just as you now buy "living" insurance, so also is the Trust Department at Fidelity ready and able to handle your investments, money, and property *while you live* and perpetuate your estate for the future when you will no longer be here to guide it.

May we have the opportunity to discuss your financial affairs in the near future?

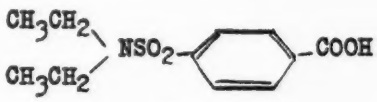
Probenecid (Benemid) in the Treatment of Gout and Gouty Arthritis



• *A number of additions to the drug therapy of gout have been reported in recent years. The author reviews the mechanism of action of one of these, probenecid, Benemid®) and outlines the practical rules he has followed in the management of his patients with gout. In discussing his results he classifies his cases into acute and chronic phases, both of which can be effectively treated.*

FRED A. RICE, M.D.
Minneapolis, Minnesota

PROBENECID (Benemid®) was developed in a search for a more effective agent than caronamide to inhibit renal excretion of penicillin.[1] It is structurally similar to caronamide and similar in many of its actions.[2]

Caronamide

Probenecid

Thus Wolfson's observation that caronamide was an effective uricosuric agent[3] was soon shown to be true of Benemid[4], and the latter is now used chiefly in the treatment of chronic gouty arthritis and the prevention of acute gout.

In addition to promoting an increased excretion of uric acid, Benemid causes a loss of phosphate in the urine. This effect has been useful in treating familial nephrogenic osteopathy and in controlling the tetany of hypoparathyroidism.[1] However, Gutman *et al*[5] did not find evidence of significant

with congestive heart failure is significant.[6] The excretion of penicillin and para-aminosalicylic acid (PAS) is lessened with an increase in the penicillin levels in serum of 100 to 1100 per cent and in the PAS levels of 15 to 30 per cent. Other antibiotics, sulfonamides and salicylates are not affected.[7]

The increased excretion of uric acid as a result of Benemid administration is due to inhibition of the tubular reabsorption of uric acid.[8] Sirota, Gutman and Yu[5] found an increased urate clearance of about four-fold, with no change in glomerular filtration rate, and a 46 to 67 per cent increase in the urate excretion, depending on the dose of Benemid. Pascale *et al*[9] found the initial increase in urate excretion, with normal renal function, to range from 35 to 200 per cent. Of particular interest is a case of Fanconi's Syndrome reported by Sirota *et al*[5] in which there was no increased urate excretion following Benemid. Apparently the defects in the proximal tubule included failure to reabsorb uric acid, and no further blocking effect could be obtained.

With the increase in the excretion of uric acid, the serum levels fall and the miscible pool of uric acid is substantially reduced.[10] Within three days the serum urate falls sharply, averaging about 45 per cent. This sharp fall is not sustained, however, and the fall over a period of several weeks averages about 32 per cent.[11] Bishop, Rand and Talbott[10] found a marked drop in the miscible pool of uric acid in two patients. In the patient with gout, the pool fell from 2205 mg. to 1622 mg. on 2 gm. of Benemid daily, and in a hyperuricemic normal individual from 964 mg. to 466 mg. The increased excretion of uric acid continues as long as Benemid is taken[12] as does the reduction in metabolic pool. If renal insufficiency is sufficiently advanced there may be no increase in urate excretion.[9]

This loss of uric acid is reflected in the clinical course of chronic gouty arthritis with lessening of pain and stiffness, the return of a feeling of well-being, failure of new tophi to develop or those already present to enlarge and, in a few cases, healing of draining sinuses, and shrinking of tophi already present. Radiographic changes may improve slightly.[13] Improved kidney function may occur.[14]

Gutman and Yu[13] reported on the course of thirty patients followed for eight months to four years. Thirty per cent failed to achieve normal uric acid levels, either because of poor kidney function, poor patient co-operation or failure of Benemid in a dose of 3.0 gm. per day. Of twenty-three patients with tophi, almost half (eleven) showed definite or marked improvement, nine were slightly better, and only three showed no change. None showed new tophi or an increase in size of already present tophi. Two of three sinuses healed, and there was a slight improvement in the x-ray appearance of involved bones in a few cases. Pascale[9] noted improvement in joint motion in all cases with impairment.

Acute gout may be temporarily aggravated by Benemid, the mobilization of uric acid seeming to act to precipitate attacks. For this reason many authorities use Colchicine routinely in starting Benemid therapy.[15] If an attack occurs it can be treated with Colchicine, as usual. As Benemid is continued, the attacks of acute gout usually become less severe and less frequent and often are completely absent after several months of therapy.[13]

Benemid is rapidly absorbed following oral administration with measurable amounts appearing in the plasma within one-half hour after a 0.5 gm. dose, and significant concentrations lasting for as long as twenty-four hours after a 1.0 gm. dose.[7] There is apparently no degradation of Benemid in the body and elimination is through glomerular filtration as a glucuronic acid complex.[16] In the normal man, a dose of 2 gm. per day will yield a

TABLE II. RESULTS IN TREATING FIFTEEN PATIENTS

Case No.	Age Onset	Sex	Duration Before Benemid	Symptoms	Maintenance Dose	Uric Acid Before	One Month	Latest	Duration Treatment	Result

15. E.K.	36	F	3 years	Knees	1.0	8.5	5.1	5.1	6 months	Good.

plasma level of 4 mg. per cent.[7] Doses in excess of this amount may cause a slow increase in the plasma concentration to the point of intoxication, with nausea and vomiting on the basis of intoxication of the central nervous system appearing at about the 30 mg. per cent level.[1] With impaired kidney function, lesser amounts may be excessive. The effective dose varies from 0.5 to 4 gm. daily.[17]

Gutman and Yu[13] report that 60 per cent of patients can be managed on 0.5 to 1.0 gm. daily, another 25 per cent on 1.5 to 2.0 gm. daily, and 15 per cent on 2.5 to 3.0 gm. daily. They did not use doses above 3.0 gm. daily, and other authorities[18,19] feel that doses over 2.0 gm. daily are rarely indicated.

Side-reactions in a series of 2,502 cases collected from the literature or observed personally by Boger and Strickland[1] are shown in Table I. Many of these patients were treated with Benemid only for a few days or weeks. In other series in which Benemid was given for longer periods of time, reactions were slightly more frequent but the various series are not strictly comparable. Apparently reactions of sufficient severity to necessitate stopping treatment occurred in 2 to 12 per cent[13,18] of cases.

Certain of the side-reactions are due to the physiologic effect of Benemid, with a large outpouring of uric acid into the urine, and precipitation of uric acid once the saturation point is exceeded. Among these are the passage of urate calculi and urate gravel, and the occurrence of hematuria, presumably from crystal and calculus irritation. Talbott[19] notes that urinary frequency is common but not troublesome. This may be related to increased acidity of the urine, but is apparently not usually due to urate gravel or calculi.

These side-effects can be avoided by starting treatment with small doses of Benemid during the first week so that large amounts of uric acid are not excreted immediately. An increased fluid intake helps to lower the uric acid concentration in the urine, and alkalinization of the urine increases the solubility of the uric acid.

Another apparently physiologic side-reaction is the presence of a reducing substance in the urine of a few patients taking Benemid. This reducing substance is thought to be the glucuronic acid which is excreted into the urine in conjugation with Benemid.

The gastrointestinal effects seem to depend on dosage since Boger and Strickland[1] report that all of ninety-one patients given 3 gms. per day developed distress. In nearly all cases of gastrointestinal irritation reported, a reduction in dose was sufficient to stop the symptoms. In a few cases Benemid had to be discontinued.

The hypersensitivity reactions have not been severe and have not been more frequent on prolonged administration. As with other drugs, intermittent courses at times seem related to development of idiosyncrasy.[1] Hypersensitivity reactions have included rashes, sore throat and fever. Marson[11] reported one case in which sweating, head-

ache and unconsciousness developed shortly after administration. The white blood count has not been reported to be affected.

The present series (Table II) consists of six patients with recurrent acute gout and nine patients with chronic gouty arthritis treated with Benemid for varying periods up to four years. Another six patients were given Benemid but are not included in the series—either because of inadequate follow-up or doubt as to the accuracy of the diagnosis. (None of these had any adverse reaction from Benemid.) In general, the response has been very satisfactory.

The patients with acute gout (Cases 1-6, Table II) were five men and one woman ranging in ages from twenty-nine to sixty-five years at the time of the first attack.

The frequency of attacks was extremely variable ranging from one episode every two years to four attacks per year. The great toes were most frequently involved, but the ankles, knees, wrists and hands were also the site of acute gout. Three of these patients had some gouty arthritis in the intervals between attacks but did not find the interval symptoms particularly troublesome.

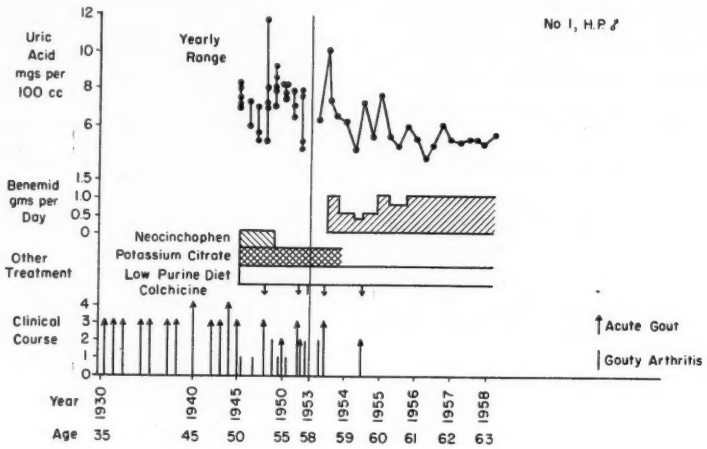

Fig. 1. Case 1 (H. P.).

Case Report

Case 1.—H. P., a white man, was first seen in 1945 with a history of gout starting in 1930 when he was thirty-five years old. He had missed having attacks only four years out of the fifteen. His attacks occurred almost always in the right great toe and in the month of March. In addition to the toe, the ankles and knees had been involved. The attacks had gradually increased in duration and in the four years prior to his first visit he had been hospitalized at the Minneapolis Veterans Administration Hospital seventy-five days in 1940 and 100 days in 1944 because of gout. In between the attacks he had had no symptoms.

His initial treatment consisted of a low purine diet; Neocinchophen, 2 gm. a day three days each week; and potassium citrate, 6 gm. a day. On this program he did very well until December, 1948, when he developed acute gout, chiefly in the right ankle, which responded promptly to Colchicine. In April, 1949, he had pain and stiffness in the right elbow for a few weeks. The Neocinchophen was discontinued in June, 1949. In September, 1950, he had a moderate attack of gout in the left great toe. In May, 1952, he had acute gout, responding promptly to Colchicine, followed by a mild attack in November, 1952. In April, 1953, he was having pain in the left knee, elbow and great toe and in May, 1953, he again had acute gout, first in the right knee, later in the right foot which again cleared promptly on Colchicine.

In July, 1953, his serum uric acid was 10.2 mg. per cent and he was started on Benemid, 0.5 gm. daily for the first week, then 1.0 gm. daily. In October, 1953, the dose of Benemid was reduced to 0.5 gm. daily (uric acid 6.4 mg. per cent) and in December, 1953, the potassium citrate was discontinued. In April, 1954, the uric acid was 4.5 mg. per cent and the Benemid was reduced to five 0.5 gm. doses a week, but on June 11, 1954, he developed acute pain, redness and swelling in the left little toe with a uric acid of 7.1 mg. per cent. The Benemid was raised to 0.5 gm. daily and he was given Colchicine with prompt relief. The uric acid remained high (7.6 mg. per cent) so in December, 1954, he was given 1.0 gm. daily of Benemid. In March, 1955, the uric acid was 5.3 mg. per cent and the Benemid was reduced to 0.75 gm. daily. The uric acid level rose slightly (5.8 mg. per cent) and he resumed taking 1 gm. Benemid daily in September, 1955, which he has

continued since that time, with uric acid levels from 4.0 to 6.0 mg. per cent. He has been completely free of symptoms since June, 1954.

In the nine patients with chronic gouty arthritis (Cases 7-15) there were six men and three women with the age at onset ranging from thirty-six to sixty-five years. All of these patients had a history of insidious onset of arthritis. None gave a history typical for acute gout prior to onset of arthritis, although three patients (Cases 9, 10 and 12) had had unexplained joint pain before definite arthritis appeared.

The arthritis followed the distribution of osteoarthritis, involving usually the back, knees, fingers, shoulders and hips. The arthritis was at times remitting, at other times was quite constant, and usually was not accompanied by heat, redness or swelling of the involved joints.

Of particular interest was the prominence of chest pain among these patients. In two (Cases 7 and 8) it was the chief complaint, and in two other patients (Cases 9 and 10) it had been present for many years, antedating the development of other symptoms which eventually led to the diagnosis of gout.

Case Report

Case 13. R. H., a white woman, was first seen in 1946. At this time she stated that she had had arthritis for fifteen years beginning in 1931 when she was forty years old, involving chiefly the hands and elbows. A diagnosis of gouty arthritis had been made about 1941. In the fall of 1946 she had a two-week to three-week period of swelling, pain and redness in the thumb and fifth finger on the right hand. She was given a low purine diet, Neocinchophen and potassium citrate, but experienced no relief of symptoms. Her fingers continued to be red and swollen nearly all of the time. Throughout the summer of 1947 the right hand was painful and continued to be painful during 1948. During the next five years she continued to have remissions and exacerbations of the gouty arthritis in her fingers, with slowly increasing deformity of the fingers and gradual involvement of the fingers of the left hand.

In 1953, she developed pain in the right knee. In March, 1954 she was started on Benemid, 0.5 gm. daily. Her uric acid was 6.4 mg. per cent. Within a week there was marked improvement. After one month the fingers were normal in color, 50 per cent less swollen, and the uric acid was 4.9 mg. per cent. However, in December, 1954 there was a flareup of the gouty arthritis in the middle finger of the left hand, which persisted for several months. In April, 1956, after stopping Benemid for three weeks, she had redness and swelling of the left sterno-clavicular joint and pain in the shoulders and hands. In April, 1957 she had no arthritic symptoms and her uric acid was 5.5 mg. per cent.

The effect of Benemid was good to excellent in fifteen of the sixteen cases as far as relief of symptoms was concerned. In Case 3, the patient was unwilling to follow any consistent plan of treatment, although he showed a good fall in uric acid in his first course. His second course of treatment appeared to precipitate an attack of gout at the end of the second week, and his third course was followed by itching and a rash one week after starting. In Case 2, acute gout occurred shortly after starting treatment. This attack was precipitated by confinement to bed because of acute epididymitis four weeks after starting Benemid. In Case 1, a mild attack occurred when the maintenance dose was reduced too much. In Case 6, an acute attack occurred six weeks after starting a second course of Benemid (0.5 gm. per day). This was probably due to the omission of Benemid, rather than any "flooding" of the body with freshly mobilized uric acid, for she had previously tolerated 1.0 gm. daily very well. In Cases 2, 4 and 6 an increase in aching and stiffness was noted when medication was not taken regularly. Proper adjustment of the dose and regular adherence to it have resulted in freedom from acute gout in each instance. The fifth patient has been under treatment too short a time to know whether his acute attacks will be prevented.

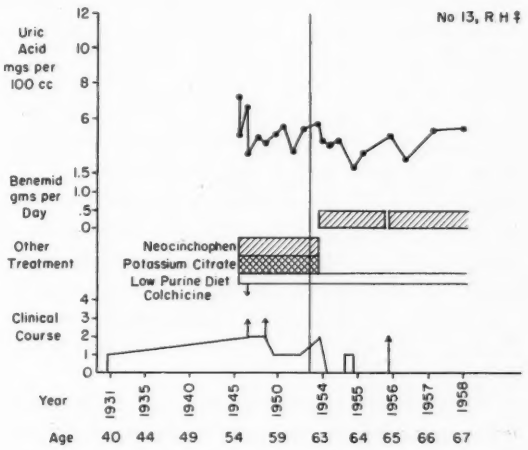

Fig. 2. Case 13 (R.H.).

All of the patients with chronic gouty arthritis have experienced sustained relief of symptoms as long as they followed the prescribed program, although three of the nine are not completely free of stiffness and aching.

In these patients the main problem has been maintenance of treatment. The less disabling symptoms have not offered as great an incentive for following the treatment program faithfully. Two patients (Cases 8 and 13), who were almost disabled by chronic gouty arthritis, have had prompt relief of their major symptoms and have followed the treatment program faithfully.

The serum uric acid levels decreased promptly in all cases, and remained so in all but one case. An attempt has been made to adjust the dose of Benemid to keep the uric acid within the normal range (4.0 to 6.0 mg. per cent in our laboratory). In Case 2, there was dramatic persistent symptomatic improvement, yet uric acid levels fluctuated, sometimes going almost as high as when treatment was started. Increasing the maintenance dose of Benemid has reduced the serum uric acid satisfactorily.

The average uric acid concentration in the blood prior to starting treatment (not including the third course in Case 3) was 8.4 mg. per cent (range 6.6 to 11.4), after one month of treatment was 6.2 mg. (range 4.8 to 7.8), and when last determined was 5.3 mg. (range 4.0 to 6.3) in those patients followed beyond the first month.

Only in Case 3 were there side-effects from Benemid. This is perhaps related to the relatively small doses used and the gradual introduction of therapy. Usually treatment was started with 0.5 gm. Benemid daily for two weeks and then 1.0 gm. daily until the patient was next seen. If the uric acid showed a satisfactory fall, the dose was reduced to 0.5 gm. daily, unless later uric acid determinations showed a need for larger doses of Benemid. At present, four patients are taking 0.5 gm. daily; eight are taking 1.0 gm.; one, 1.5 grams and one, 2.0 grams. The two who died were on 0.5 gm. at the time of death. Of the six patients who took 0.5 gm. per day four did not achieve normal uric acid levels and it is likely that the proper maintenance dose for the two of the four who are still living will prove to be 1.0 gm. daily.

Summary

1. Benemid has been found to be a safe and effective agent for the treatment of chronic gouty arthritis and the prevention of acute gout.

2. A series of six patients with recurrent acute gout and nine patients with chronic gouty arthritis treated with Benemid for periods up to four years is reported.

3. In one case treatment had to be discontinued because of a possible drug rash.

4. In all patients who followed the recommended program, the uric acid was brought to normal or near-normal levels and the symptoms were markedly alleviated.

Varicose Veins and the General Practitioner

● The pathological entity of varicose veins is seen frequently in general practice. Here is a clear, concise and valuable discussion which will help one to approach the problem intelligently, decisively and efficiently.

H. O. McPHEETERS, M.D.
Minneapolis, Minnesota

IN the treatment of varicose veins we must realize that we are dealing with a progressive, degenerative condition of some of the vein walls. Any vein in the body may be involved but it is most common in the superficial veins of the lower extremities.

This condition may be congenital or develop secondary to many factors. The end result is the same: large dilated varicose veins with a reverse blood-flow and stagnation, secondary lymph stasis, edema and later a dermatitis and ulcer formation.

The title of this presentation, "Varicose Veins and the General Practitioner" was chosen because he is the one who is usually first consulted by the patient.

The early history of the treatment of varicose veins is so well known that, for the sake of brevity, it will be omitted. Beginning about 1900, the condition received much attention. Trendelenburg[1] made such a marked study of the condition that his name will always be linked with its treatment. Delbet[2] was most radical and did almost mutilating operations at times. Later, Babcock[3] Charles Mayo,[4] Matas[5] and John Homans[6] made great strides in their surgical treatment and our care of varicose veins today largely follows their teachings.

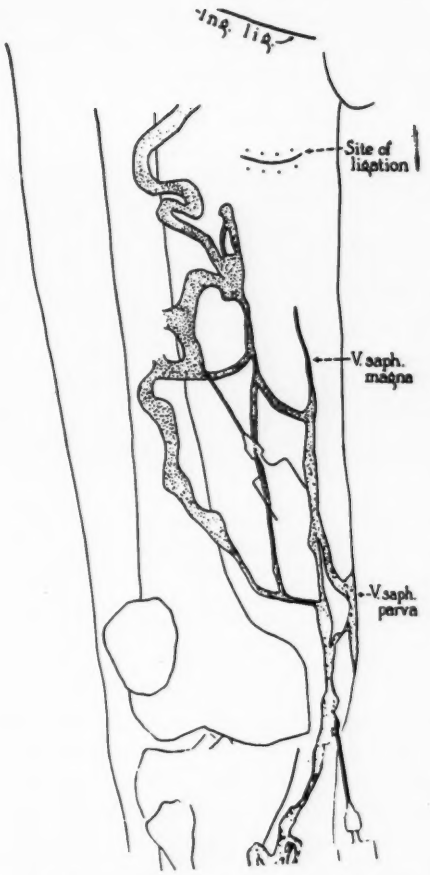

Fig. 2. Simple high ligation without either stripping or postoperative injections. It should be mentioned only to be condemned.

The injection treatment of varicose veins began with the invention of the Pravaz syringe in 1853. Many different solutions have been used with many and varied techniques. All have been used with the same basic theory of causing "a sufficient irritation to the intima of the vein to cause a thrombus to form and secondarily obliterate the vein lumen." In my experience (and in that of most surgeons) this has proved to be a failure. Karl Sigg is the only man of international prominence who treats all varicose veins by injections only.[7] He does no surgery on them other than to evacuate softened thrombi in the larger injected veins. He uses the Air-Block technique of Orbach[8] with some modifications. He claims exceptional results with many thousands of patients. For my-

Presented before the Wisconsin Chapter of The American Academy of General Practitioners, Milwaukee, Wisconsin, Sept. 15, 1958.

self, I use the Air Block plus my empty vein technique with the tourniquet. The dose varies with the solution used and the size of the vein being treated.

Fig. 1. Empty vein technique of injections. Leg has been elevated and varices drained of blood. Patient was lying on table. Tourniquet was applied and injections were made. The patient then sits up so the back pressure in the deep veins holds most of the injected solution in the varicosed segments. The ACE bandage is applied after the needles are removed and the patient is then instructed to walk a lot.

Briefly, the empty vein technique presupposes that the irritation of the solution would be more severe, evenly spread and better controlled if the solution was injected into the empty vein and not diluted with blood. Only small ½ cm. veins, the spider veins and those scattered segments remaining after surgery are amenable to the injection treatment. All perforators must be dissected and ligated.

The vein distribution is well studied with the patient standing on a stool. The actual point of injection is selected and marked lengthwise of the loop. The patient then lies down with the foot resting on a stool. A 2 cc. syringe containing the solution is fitted with a 1½ inch sharp, short beveled, 23 gauge needle which is inserted into the vein. While holding the foot and leg elevated to drain all the varicosed segments, the tourniquet is applied 8 to 10 inches above the segment being injected (Fig. 1). The foot is lowered to a footrest below level of the body and the solution is injected. With care and experience, this maneuver can be done well and without getting the needle point out of the vein. After the injection the needle is shoved through the vein thus transfixing it. All injections are made as quickly as possible and then the patient is allowed to sit up and rest for three minutes. This allows the solution to damage the intima sufficiently. The needles are then withdrawn and pads of cotton or gauze strapped over the site of the injection and an Ace bandage is applied. The patient then must walk four to six blocks immediately and continue much walking that day. This will wash out the solution that may have spilled over into the deep veins. A firmer and smaller thrombus will form if the bandage is worn very tight for several days.

The solutions most commonly used today are Sylnasol, Sodium Morruhate and Sotradecol.[7,8] As for myself, I still prefer Sylnasol; Sigg uses Sotradecol 1 per cent and 3 per cent strength in ¼ to ½ cc. doses. The injection treatment is much more effective if an emulsion is made by repeatedly withdrawing the solution from the vial and then forcing it back in under pressure. Thus you can make a fine foam. It is the only way it should be injected into the spider and the smaller veins. It is also better for the patient to wear the Ace bandage for several days. After seven to ten days as much of the fine thrombus should be evacuated as possible, using a number 11 blade and digital pressure. No anaesthesia is needed.

As stated above, practically all physicians today treat varicose veins surgically. The more thoroughly the job is done the better and longer lasting will be the result, Sigg to the contrary. All treatment is based on the acceptance of the idea of the reverse flow. This is easily demonstrated by the Trendelenburg test,[1] the multiple tourniquet test,[9] the milking test,[10] blood pressure readings in the veins,[11] and by palpation.[12]

Any good anaesthesia is suitable for this work. The author prefers a carefully given spinal. If done with a small 22 gauge needle and the newer technique there will be very few postoperative headaches. Pentothal Sodium is fine except for the nausea that many patients develop and as a rule they cannot ambulate as soon as under the spinal or local. Procaine plus marked sedation serves very well and has been used a great deal. I used it entirely for many years.

Special emphasis must be made of the preoperative study and marking of the veins.[12] Locate the foramen at the groin, mark the course of the saphenous through the thigh and all the varicosed segments. Search carefully for perforators. With firm digital pressure along the veins actual holes can be felt. It is very tender there and the patient will wince with pain each time as you come back and press in at that point. These are most com-

monly found along the inner lower thigh, inner all of the tibia and calf, mid-line of the calf and internal and just below the ankle. At surgery follow these pre-operative markings carefully. The perforators above the ankle and just below it may be the cause of an ulcer not healing or a dermatitis not responding to treatment.

Any surgery should be condemned as "puttering" that does not include a carefully done *high sapheno-femoral* ligation flush with the femoral vein (Fig. 2). This must be followed with a thorough dissection and ligation of all the perforators sub-fascially and a suturing of the hole of emergence.[13] Then all the varicose segments must be dissected and stripped out. I prefer the pliable Linton stripper in a set of three. The vein can be stripped either up or down. When the traction on the stripper shows a pulling in of the fat as the stripper head passes along, it means there is a large branch there. It should be cut down on and later dissected out. Incisions, adequate in size and number must be made to do this. At times this is best done with many small 1-inch incisions while at other times, long incisions with almost a block dissection must be used. I seldom use the radical Linton and Felder dissection but the incisions must be adequate and the work *must* be thorough.

A plexus of veins is often found below the popliteal space from the short saphenous and extending into the muscle of the calf. This should be dissected out.

At times the main popliteal vein is found to be widely dilated and sacculated. In that case, it remains filled with stagnant blood whenever the patient is standing. The blood pressure in the popliteal vein in such a case would be equal to the pressure of the venous column from the right heart down. It measures 40 mm. Hg. at the groin, 60 mm. at the knee and 100 mm. in the calf in the extensively developed case of varicose veins. Thus we would expect it to be 80 mm. to 100 mm. in the popliteal vein. This would allow the high back pressure on the valves in the communicating veins and thus blow them open. This is the reason we so often find new perforator veins and that new varicose vein formations develop after surgery.

The fact that we have had "no emboli" in over 9,000 ligations done during the past fifteen years proves that patients should have early and rapid ambulation. Elastic bandages (4-inch Ace) must be worn as long as there is any swelling.

Beginning two months postoperatively, all remaining varicosed segments must be injected at one-week to three-week intervals and the patient must be seen at yearly intervals thereafter.

The complications of varicose veins: phlebitis, dermatitis, ulcers, and so forth, deserve a special presentation. However, their prevention should be emphasized here because their best treatment is prophylactic.

INSTRUCTIONS FOR HOT PACKS

Must be bed rest. Useless to sit in a chair with the leg resting on another chair, and try to apply hot wet packs.

Body must be lying flat. Only one pillow under head.

Knee should be flexed slightly with the lower leg high on a pile of pillows 16 inches above level of mattress.

Best if the lower leg (knee to foot) is about on the level with the knee slightly flexed.

Packs should be applied at least 10 inches both above and below the area to be treated.

Temperature of packs should be 120 degrees to begin with and then increase as tolerated. Preferably to 130 degrees if the patient should not object.

Fresh packs should be applied as quickly as possible at time of change to prevent the cooling of the skin.

The packs are best applied by:

1. Folding a blanket four times and placing on top of a pile of pillows.
2. Fill the hot water bottles (several, one-half full) with hot water and right temperature. Compress the air out of the bottles as cork is tightened.
3. Wring the large bath towels and woolen blankets out of hot water. Quickly apply the wet towels, then the hot water bottles and then quickly wrap the blanket about it all and pin tightly.

If the above pack is properly applied, it will stay hot for at least two hours, and it should all be changed every two hours.

Best results will be obtained if the packs are continued for not less than four hours at a time.

When the ACE bandage is used and applied it is best if the patient walks a great deal.

Summary

The pathological entity of varicose veins is one of the most commonly seen in a general practice. Its care and treatment rightfully belongs in the hands of the general practitioner. He should acquaint himself with all the tests used in study of the case at hand and then qualify himself to do the best job of surgery possible in treating the condition. New varices will form as time goes by and pregnancies intervene. They should be analyzed and treated with the same thoroughness as was the original case. All patients should be rechecked yearly.

Plastic Operations o[n] t[he] E[yelids]

THADDEUS J. LITZOW, M.D.
Rochester, Minnesota

DEFECTS of the eyebrows and eyelids are conspicuous, some bordering on the grotesque; they demand correction for cosmetic reasons. Equally important, or more so, is the functional need of eyelids for preservation of vision. There are many congenital and acquired defects of the eyebrows and eyelids, and a multiplicity of methods for their repair. Only some of the more common defects and reparative methods will be discussed here.

A torn and displaced portion of the eyebrow that has healed in its new position disrupts the natural curve of the brow. The displaced portion can be repositioned by an interchange of triangular flaps known as a Z plasty (Fig. 1).

Partial or complete absence of the eyebrow requires replacement with hair-bearing skin. The easiest and most expedient method is the use of a hair-bearing free skin graft (Fig. 2). Such a graft can be taken from the scalp behind the ear without residual deformity of the scalp. The graft should be so cut and placed that the direction of the hairs corresponds with the lateral direction of the hairs of the eyebrow.

Fig. 2. *a.* Eyebrow and eyelid lost by trauma. *b.* After correction by skin grafting.

A small epithelioma in the eyebrow can be widely excised with a vertical incision. Microscopic examination of fresh frozen sections immediately after removal verifies the clinical diagnosis and determines adequacy of excision. Primary closure in a vertical direction restores the con-

e Eyebrows and Eyelids

● Patients with defects of the eyebrows and eyelids need corrective surgical treatment both for the psychologic value of cosmetic improvement and for preservation of visual function. The author describes and illustrates a number of plastic surgical technics designed to aid correction of such distressing defects.

tinuity of the eyebrow. The small amount of foreshortening is not noticeable and is much preferable to leaving an area devoid of hair (Fig. 3). Benign tumors can be removed similarly, with less sacrifice of tissue.

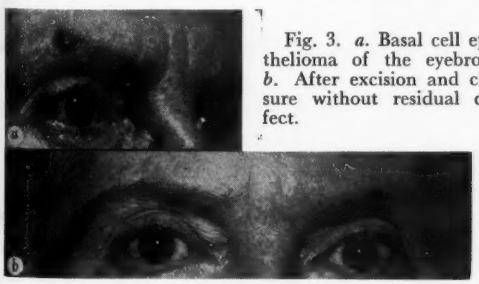

Fig. 3. *a*. Basal cell epithelioma of the eyebrow. *b*. After excision and closure without residual defect.

Small benign tumors of the eyelids, such as nevi, can be removed easily for microscopic examination, with light electrocoagulation of the base of the wound. The resulting small scar is not unsightly and requires no further treatment (Fig. 4). Simple excision and primary closure constitute another method frequently used.

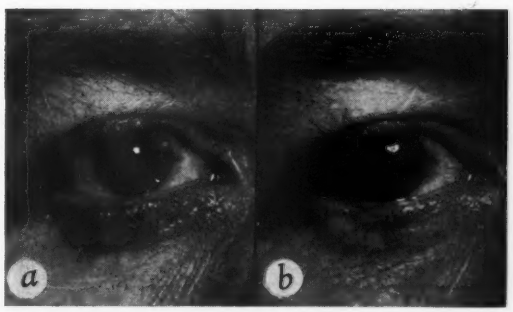

Fig. 4. *a*. Intradermal nevus. *b*. After surgical removal and light electrocoagulation of the base.

Excision of epitheliomas calls for wider removal, with greater attendant sacrifice of tissue. Those that have penetrated the skin and invaded the deeper structures require full-thickness excision of the eyelids. If one third or less of the width of the eyelid has been sacrificed, the defect usually can be closed by direct apposition and suturing of the wound edges. Sacrifice of more than one third of the width of the eyelid entails more extensive procedures for repair.

A fairly large epithelioma (Fig. 5) that requires sacrifice of the skin only can be corrected by a local sliding skin flap. Although the missing eyelashes are not restored, lack of them is not a source of discomfort to the patient nor cosmetically unattractive. The basal cell epithelioma seen in Figure 6 was treated by this method. If the epithelioma is in the medial half of the eyelid (Fig. 7), repair is accomplished with a local skin flap and a full-thickness skin graft is used to cover the donor site. The basal cell epithelioma seen in Figure 8 was treated thus. Establishment of the adequacy of removal by microscopic examination of fresh frozen sections from the specimen can give the plastic surgeon the opportunity for reconstructive measures at the time the lesion is removed.

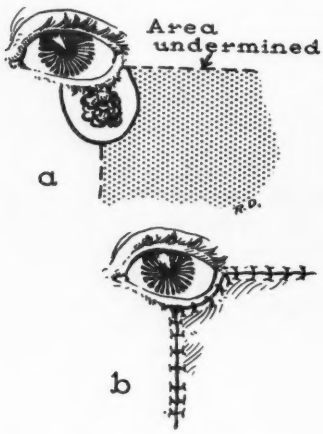

Fig. 5. *a*. Removal of lesion from left lower eyelid and preparation of local sliding skin flap. *b*. Closure.

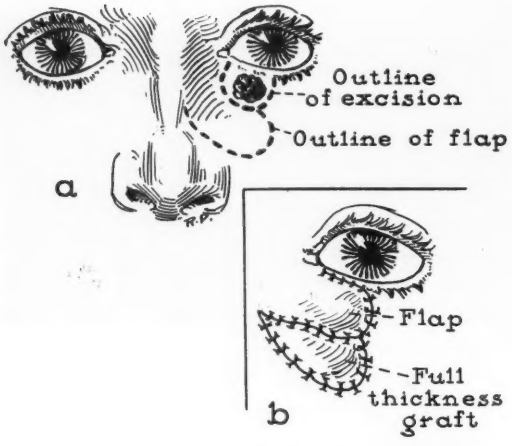

Fig. 7. *a*. Removal of lesion from medial portion of lower eyelid and preparation of local sliding skin flap. *b*. Repair of the defect with skin flap and full-thickness graft.

Fig. 8. *a*. Basal cell epithelioma of medial portion of lower eyelid. *b*. After excision and repair as indicated in Figure 7.

Loss of a major portion of the skin of the eyelid by physical trauma or thermal burn results in extensive scarring with shortening and ectropion. As the shortened eyelids cannot be closed, there is much discomfort. Usually, for this reason or for cosmetic improvement, the patient seeks out the plastic surgeon. A full-thickness skin graft with a good color match is best suited to correct the defect, and a graft fulfilling the requirements can be obtained from the postauricular region. The patient seen in Figure 2 had such a graft taken

from behind one ear, and later a second graft taken from behind the other ear, to give the total effect shown on the right upper eyelid. The grafts taken should be ample in both width and

Fig. 9. length. The patient seen in Figure 9 had had extensive thermal burns on the left upper and lower eyelids, with subsequent grafting of full-thickness skin taken from behind both ears. Being too small, the grafts had left the patient with the deformity

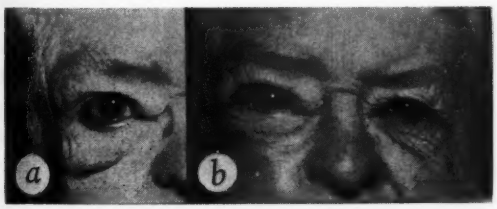

Fig. 11. *a.* Deformity of eyelid and redundancy of tissue after right facial paralysis. *b.* After correction.

shown. As all available skin had been taken from behind the ears, a split-thickness skin graft from the abdomen was used for correction, with the six-month results pictured. The patient was offered, but refused for the time being, a transfer of hair-bearing skin to replace the missing portion of the eyebrow.

Many of the injuries to the eyelids sustained in automobile accidents are lacerations involving little loss of tissue and no damage to the eye. Simple cleansing and closure with fine suture material, preserving all viable tissue, is sufficient (Fig. 10). When the loss is extensive, as in the case of the patient in Figure 2, reconstruction should be started as soon as possible. Unnecessary delay results in formation of much scar tissue that distorts the remaining normal tissues. Removal of the scar tissue and correction of the distortion add to the difficulties of the operation and detract from the final result.

Paralysis of the orbicularis oculi muscle is manifested by the patient's inability to close the eyelid and a greatly widened palpebral fissure, and occasionally by persistent epiphora. The correction—

Fig. 10. *a.* Lacerations of the eyelids, eyebrow and scalp. *b.* Appearance 10 days after repair which immediately followed injury.

lateral blepharorrhaphy, conducted under local anesthesia—consists in denuding a measured length of the free edge of the eyelids and suturing the raw edges together. This reduces the size of the palpebral fissure and makes the eye more comfortable, and the resultant appearance is close to normal.

When the skin of the lower eyelid is redundant, as seen in Figure 11, an alternative procedure is effective in removing the excess skin and also accomplishing the results obtainable with the first procedure. A horizontal incision is made at the temporal canthus, and through this incision the skin of the lower eyelid is undermined. A V-shaped excision of the tarsus and conjunctiva at the temporal canthus snugs up the eyelid and reduces the size of the palpebral fissure. The undermined skin is drawn laterally, the excess is excised and discarded, and the skin is sutured in its new position.

For most of the conditions discussed in this paper a single method of repair has been presented. Usually that method is the one most commonly employed. There are other methods, however, some equally good and many of sufficient merit to deserve the consideration of the surgeon in his choice for the problem at hand.

Incidence of Congenital He[ease]
Register[rses]

● *The authors estimate that there is one child with congenital heart disease in 186 live births. One can calculate from this that there are almost 450 new congenital heart cases added to the population of Minnesota each year.*

AMONG early work done in an attempt to determine the incidence of congenital heart disease was that of Rauh,[1] who surveyed the elementary and secondary schools in Cincinnati in 1939. Among the 58,611 children examined, ninety-five had "proven" congenital heart disease, or one in every 625. However, this study did not include children under age five; thus many individuals with serious lesions which had caused their demise before the age of five years were not included. In addition, there surely were children with undiagnosed defects of benign nature, such as some cases of patent ductus arteriosus and the ostium secundum type of atrial septal defect.

Robinson and Aggeler[2] performed a similar survey in San Francisco in 1947. Again, elementary and secondary school students were examined. One in 500 children was found to have congenital heart disease. It is to be remembered that more accurate cardiologic instruments, such as cardiac catheterization, were now available. This may explain the slightly higher incidence.

Gardiner and Keith[3] in 1951, reported a survey of children under age sixteen in Toronto. Not only were school children examined, but also an effort was made to include all postmortem examinations, child health center examinations, and examinations by private physicians. Each child suspected of having organic heart disease was referred to a central registry where a more thorough evaluation could be conducted. Among 134,467 children examined, 291 were found to have congenital heart disease, an incidence of one in 455 children.

In 1953, MacMahon, McKeown, and Record[4] reported on an extensive survey performed in Birmingham, England. They canvassed all postmortem and clinical records of hospitals, schools and death registries in an effort to locate all known cases of congenital heart disease in infants born during the years 1940-1949 within the limits of the city of Birmingham. Among 199,418 births during this period, they discovered 633 cases of congenital heart disease—an incidence of one in every 315 births.

In a more recent study published in 1955, Richards[5] and her group at Columbia Presbyterian Medical Center in New York City followed the offspring of all pregnancies delivered in their hospitals during the years 1946-53 for one year. Among 6,053 infants, fifty were believed to have

congenital cardiovascular malformations. Twenty-five of these fifty had their lesions proved either by operation or autopsy. The incidence was one in every 120 births. In comparing their study to MacMahon's, these authors attributed their much higher incidence to closer supervision, greater

Important Notice

The nurses of Minnesota who are mothers are being asked to take part in a study designed to determine how many infants per 100 normal infants are born with malformations of the heart, their life expectancy, and their outlook in the future for curative treatment. To be accurate, a response from you is needed concerning all children borne by you, both normal and abnormal.

We feel that your greater knowledge of medical problems, your desire to help children so afflicted, and your willingness to add to medical knowledge will prompt you to return this information to us by **July 21, 1957** to be included in the study!

Fig. 1. The survey questionnaire.

interest in malformations, and a higher rate of autopsies.

It is apparent that a wide variation in estimates of the incidence of congenital heart disease exists in the literature (Table I). In an attempt to obtain a more realistic estimate by means of a short-term study, a survey was made of the 14,614 registered nurses in the state of Minnesota. The results of that survey are the subject of this communication.

TABLE I. INCIDENCE OF CONGENITAL HEART DISEASE IN VARIOUS SURVEY POPULATIONS

Study	Year	Incidence
1. Rauh[1]	1939	1:625 children
2. Robinson and Aggeler[2]	1948	1:500 children
3. Gardiner and Keith[3]	1951	1:455 children
4. MacMahon, et al[4]	1953	1:315 births
5. Richards, et al[5]	1955	1:120 births

Methods and Materials

The offspring of the registered nurses of the state of Minnesota were used as the base population of the survey. Nurses, it was felt, would be more inclined to respond to an appeal for aid in medical research. It was also felt that the medical care received by their offspring would, by and large, be superior to that of the average of the population, and that any diagnosis of congenital heart disease on any of their children would be more thoroughly followed and more accurately recalled.

A questionnaire form was prepared (Fig. 1). This was sent to each of the 14,614 registered nurses on June 30, 1957, along with their 1958 license renewal forms. Although the license renewal forms were not due back to the State Board of Nursing until January 1, 1958, we requested that the questionnaire be returned by July 21, 1957. We accepted no more survey replies after August 15, 1957.

Only registered nurses who were mothers were asked to reply. Although it was impossible to determine how many of the 14,614 nurses were mothers, it was known that 8,343 (or 65.6 per cent) were either married, widowed, or divorced, and it was assumed that all of these were mothers.

The mothers were asked "*Does (did) the child have congenital heart disease?*" and then they were requested to specify the type of malformation.

By August 15, 1957, the State Board of Nursing had received 6,500 license renewals. If we assume the same ratio of married, widowed, or divorced as above (65.6 per cent), this would mean that, of the 6,500 renewals, 4,264 should have replied to the questionnaire. As of August 15, we had received 3,834 replies, or 89.9 per cent of the possible 4,264*. We felt that the response validated the survey.

There were a total of 8,546 children listed on these questionnaire replies, an average of 2.23 children per reply. These 8,546 formed the base population for the survey.

Each survey reply was reviewed. If it was felt that there was even the slightest suspicion of a congenital cardiovascular malformation, it was held for further review. Two of us (P. A. and R. C. A.) independently and blindly classified these suspicious forms as outlined below. Those few forms where there was disagreement were resolved at a general session of all those concerned with the project.

Results

The survey replies were classified as follows:

Group 1. This group included all cases where the malformation was specifically listed by the replying mother. In most of these replies, the mother stated that the clinical diagnosis had been confirmed by autopsy, surgery, or special studies. There were thirty-eight individuals in this group.

Group 2. This group included all cases where congenital heart disease was probable. Although the mother answered "yes" to the question "*Does (did) child have congenital heart disease?*" no specific malformation was listed. The additional remarks of the mother, however, were strongly suggestive of congenital heart disease. There were eight individuals in this group.

Group 3. This group included all cases where the mother had answered "yes," her child did have congenital heart disease. However, no specific diagnosis was listed and the accompanying remarks were not suggestive of congenital heart disease. There were sixteen individuals in this group.

*The 3,834 replies we received actually represents only 45.9 per cent of the possible 8,343 eligible registered nurses in Minnesota. However, since the mailing stated that licenses need not be renewed until January 1, 1958, many forms were received after August 15. These were not included in the survey because of the limitation in time available for this project.

Our initial reaction was that mothers with children having congenital heart disease might be more motivated to reply to the questionnaire than the average nurse. To evaluate this, we conducted an internal validity check; in the Heart Clinic of the Variety Club Heart Hospital, we had records of thirteen children whose mothers were registered nurses in Minnesota. Of those thirteen, only five (38.5 per cent) replied by August 15. This was even less than the over-all ratio of nurses who had replied by August 15 (45.9 per cent). It seems likely that mothers with offspring with congenital heart disease were not more motivated to reply to the questionnaire.

Group 4. In this group were included those replies where the mother had placed a question mark after the question *"Does (did) child have congenital heart disease?"* The history most often was compatible with a functional murmur. There were sixty-one individuals in this group.

Group 5. This group includes all replies where no congenital heart disease was mentioned. There were 8,220 individuals in this group.

The problem then arises—*How do we define the incidence of congenital heart disease?* Should we include only Group 1 (proven cases)? Then $38/8546 = 0.44$ per cent, or an incidence of one in 225 births.

Or should we include Groups 1 and 2 (proven and probable cases)? Then, $46/8546 = 0.54$ per cent, or an incidence of one in 186 births.

Or should we include Groups 1, 2, and 3 proven, probable, and suspicious cases)? Then, $62/8546 = 0.72\%$ or an incidence of one in 139 births.

Thus, our range is from one in 225 births (in the narrowest sense) to one in 139 births (where we are even including suspicious cases, which are most likely non-organic in nature). It appears that neither of these values is appropriate and that, for this survey, the correct incidence of congenital heart disease among the offspring of the registered nurses of the state of Minnesota would be the figure which includes Groups 1 and 2, or one in 186 live births. Unfortunately, it was not feasible to do follow-up studies on suspected cases.

TABLE II. ASSOCIATION OF MATERNAL AGE WITH THE INCIDENCE OF CONGENITAL CARDIOVASCULAR MALFORMATIONS
(Minnesota)

Maternal Age	Controls (43)	Groups 1 and 2 (46)
17-21 years	2.3%	4.3%
22-26 years	37.2%	34.7%
27-31 years	32.6%	34.7%
32-36 years	18.6%	15.3%
37+ years	9.3%	11.0%

Discussion

The ideal survey of the incidence of congenital heart disease would follow a very large group of persons from birth to death and autopsy. This must be regarded as an unattainable goal in view of the practicalities of modern research. An accurate estimate would be an acceptable substitute, and this is what this survey has tried to provide.

One other question which we thought this survey might be able to answer was the matter of a possible association between age of mother at time of birth and the incidence of congenital heart disease in these offspring. MacMahon[6] had investigated this problem in connection with his work on congenital malformations in Birmingham, England. He compared 588 children with clinically-proven congenital heart disease with a series of 1,015 controls, selected by taking every 200th birth from the city records.

To quote, "Differences between the two series are not significant." However, MacMahon did find that thirty-five of his 588 children with congenital heart disease were afflicted with Mongolism. Of these thirty-five, twenty-six (73 per cent) were born of mothers aged thirty-three years or more—a highly noteworthy figure.

TABLE III. ASSOCIATION OF BIRTH RANK WITH INCIDENCE OF CONGENITAL CARDIOVASCULAR MALFORMATIONS
(Minnesota)

Birth Rank	Controls (43)	Groups 1 and 2 (46)
1	41.9%	50.0%
2	32.6%	26.1%
3	18.6%	17.4%
4	2.3%	2.2%
5	4.6%	4.3%

Along the lines of MacMahon's study, we selected a control series of forty-three persons by taking every 200th person reported on this survey. This control series of normals was compared with the forty-six individuals in Groups 1 and 2. The results are shown in Table II. The children are grouped according to maternal age in five-year periods. No real association between age of mother at time of birth and the incidence of congenital heart disease in the offspring is evident.

The possibility of an association between birth rank and congenital heart disease was also considered. MacMahon[6] had found no consistent relationship in his series of 588 affected children and 1,015 controls. Richards and her group[5] at Columbia Presbyterian noted a slight increase in incidence with increasing birth rank but stated that no really significant relationship existed.

Our findings are shown in Table III. The percentage of first-born children with congenital heart disease is slightly higher than that of first-born controls. However, this difference is not statistically significant in view of the small number of individuals in each group, and there are no other significant differences in the other groups.

TABLE IV. SPECIFIC LESIONS REPORTED IN MINNESOTA SURVEY

Defect	Total Cases	Sub-Total Cases	Deaths	Per Cent Mortality	Average Age at Death	Alive	Average Age	Remarks

A consideration of the thirty-eight persons in Group I (specific diagnosis listed) revealed that 24 (63.2 per cent) were dead at the time of survey (Table IV). Only two of the thirty-eight had been subjected to surgery: a twelve-week-old child with reversing patent ductus arteriosus, and a three-year-old with interatrial septal defect and anomalous inferior vena cava. Both of these children died subsequently.

By far the most common malformation cited was interventricular septal defect. Of the twelve cases reported, five or 41.7 per cent were dead, the average age at death being only seven days. The seven survivors averaged eleven years of age at the time of the survey.

The next most common malformation was coarctation of the aorta. There were four cases reported. Three were dead with a mean age at death of only two days. The one survivor was fifteen years old. The three atrial septal defects reported were all complicated by additional lesions, one by patent ductus arteriosus, one by mitral insufficiency, one by anomalous inferior vena cava. The three cases of cortriloculare biatriatum (single ventricle) all were dead, the mean age of death being only three days.

Summary

A questionnaire survey of the offspring of more than 14,000 registered nurses in the state of Minnesota was conducted in the summer of 1957 with the goal of defining more accurately the incidence of congenital heart disease. One child with congenital heart disease in every 186 live births can be regarded as a fair minimal estimate of the incidence of such malformations.

In agreement with other investigations, we were unable to find any significant differences in maternal age or birth rank between children with congenital heart disease and normal controls drawn from the same base population.

Of all the children reported with congenital heart disease, nearly two-thirds had died by the time of the survey, the great majority having died within weeks after birth.

Acknowledgment

Sincere appreciation is expressed to the registered nurses of the state of Minnesota whose response was so outstanding, and also to the Minnesota State Board of Nursing Examiners (Miss Lenore Collatz, Executive Secretary) without whose co-operation this survey would never have been consummated.

Effect of Chlorothiazide on Patients with Edema of the Lower Extremities of Local Origin

● *One of the most promising of the new diuretics designed for oral use is chlorothiazide. Its field of application is constantly widening. This study outlines its use to correct chronic dependent edema of local origin in a group of state-hospital patients.*

NELSON W. BARKER, M.D.
BEVERLY CAREY, M.D.
WILLIAM BROUGH, M.D.
Rochester, Minnesota

CHLOROTHIAZIDE is a potent oral diuretic whose effects have been demonstrated in animals[1] and humans.[2] This agent not only increases the secretion of water by the kidneys but also that of sodium and chloride and, to a lesser degree, of potassium and ammonium.[3] The potency of this drug as a diuretic agent is comparable clinically to that of the mercurial diuretics. It is effective in causing pronounced reduction or disappearance of edema associated with such conditions as congestive heart failure, the nephrotic syndrome, hepatic disease and toxemias of pregnancy.[3,4] The effectiveness of chlorothiazide as a diuretic and saluretic does not appear to diminish with continued use. When it is given as a diuretic, the usual total doses have been 0.5 to 2.0 gm. a day usually given in two or three divided doses.

We have confirmed the effect of chlorothiazide* administered orally as a diuretic in the elimination of the edema of congestive heart failure in a small series of cases. We also used chlorothiazide in the treatment of a patient who had advanced lymphosarcoma involving the axillary, cervical and inguinal lymph nodes and the spleen, with associated extreme edema of both lower extremities and moderate ascites. The edema and ascites had been progressive for a month when chlorothiazide was first administered, and the use of this diuretic resulted in progressive and complete disappearance of the edema of the lower extremities and the ascites, with loss of approximately 20 pounds in one week.

From the Rochester State Hospital and Mayo Foundation, Rochester, Minnesota.

*The chlorothiazide (diuril) used in this study was supplied by Merck Sharp & Dohme.

Present Study

Because of these experiences, we undertook a study of the effect of chlorothiazide given orally on a series of patients who had chronic edema of the lower extremities of local origin. The patients were primarily under treatment for mental illness at the Rochester State Hospital. For several months prior to the study, and during the control and the test periods, these patients remained under the same environmental conditions. They slept in the horizontal position without elevation of the lower extremities, their daily routine of physical activity, sitting in a chair and ambulation was not changed, and they ate the same regular hospital diet without restriction of sodium chloride. It was estimated that this diet contained at least 4 gm. of sodium chloride a day. None of these patients had evidence of nutritional deficiency, all were eating adequately, and none had evidence of congestive heart failure, hepatic disease or renal disease as possible causes for the edema of the lower extremities. Elastic bandages or supports were not used on the legs during the control period or the period of treatment.

During both the control and the treatment periods, the patients were weighed daily during the late afternoon or early evening, and measurements were made daily at the same time of the girth of the legs around the midcalf and just above

the ankle. Weights and measurements were determined at the same time of day for each patient during the entire study. The late afternoon was selected as the time for these weights and measurements because it was thought that the edema of the lower extremities would be maximal at this time during each twenty-four-hour period. During the control period and twice during the treatment period, each patient was examined and an estimation was made of the degree of pitting edema in the involved extremities. This was graded on the basis of 1 to 4. These examinations were carried out between 9 and 10 a.m.

TABLE I. EFFECT OF CHLOROTHIAZIDE ON CHRONIC LYMPHEDEMA OF LOWER EXTREMITIES

Case	Age, Years	Sex	Grade of Pitting Edema		Mean Weight Change During Treatment, Pounds	Mean Change in Circumference, Inches	
			Before Treatment	During Treatment		Calf	Ankle
1	53	F	2	1−	−1.6	−0.5	−0.5
2	77	F	2+	1−	−3.4	−1.5	—
3	58	F	2+	0	−3.2	−0.5	−0.3
4	48	F	2	0	−2.7	−0.5	−0.6

After the control observations had been made for a period of six to ten days for each patient, chlorothiazide was administered orally in doses of 0.5 gm. twice daily. After this amount of chlorothiazide had been given for seven to ten days, the dose was increased to 0.5 gm. three times daily for another period of seven to ten days. Each patient's weights for the control period were averaged and compared with the weights during the treatment period. The measurements of the involved legs for each location also were averaged for both the control period and the treatment period for comparison.

Causes of Edema in Patients Studied.—A total of twenty patients was treated. Of these, four were diagnosed as having chronic lymphedema; the lymphedema in two of these was of the post-inflammatory type and had followed one or more episodes of diffuse lymphangitis and cellulitis of the limb, whereas the cause of the lymphedema in the other two was uncertain and the condition was apparently a long-standing one, possibly representing so-called lymphedema praecox.

In eight of the patients, the cause of the edema was considered to be chronic venous insufficiency. All these patients had moderate to extensive varicose veins, and most of them had incompetency of the greater saphenous system. Most of them had other evidence of venous insufficiency, such as stasis pigmentation, local eczematoid changes in the skin and scars of previous stasis ulcers. The edema in some of these patients was unilateral, and in all it was worse in one leg than in the other, corresponding to the more extensive varicosities and changes in the skin.

In the remaining eight patients, the edema was designated as an idiopathic sedentary type, since there was no clinical evidence of lymphedema or local venous insufficiency or of cardiac, renal or hepatic disease. These eight patients were physically inactive, spending all or most of the day sitting in a chair. The edema was bilateral and was of essentially equal degree in both legs. It pitted easily, and the skin was soft and did not show the changes characteristic of either lymphedema or venous insufficiency. Dependency and lack of muscular activity in the legs were thought to be important factors in the production and maintenance of the edema in these patients, but other factors such as disturbances in nutrition, retention of sodium chloride, muscular and cutaneous atrophy secondary to aging, and possibly prolonged mental illness could not be excluded.

Results

The clinical effects of chlorothiazide are summarized in Tables I, II and III for each of the afore-mentioned three groups of patients, respectively. In these tables, the mean change in weight during treatment was computed as the difference between the means of the daily weights during the control period and the treatment period. The figures given for the degree of pitting and for the measurements are those for only one extremity for each patient, this being the one with the greater degree of edema when both legs were affected. The figures for the change in mean girth of calf and of ankle were computed as the difference between the mean of all the measurements during the control period and the mean of all measure-

ments during the treatment period for this limb for each patient.

As noted in Table I, the effect of chlorothiazide on the four patients with lymphedema was striking and rather consistent, since the edema was reduced to grade 1- or zero in all. None of these patients had extreme degrees of lymphedema when the treatment was started, although it was of at least moderate severity in all. The effects were somewhat less pronounced in the two patients with postinflammatory lymphedema than they were in the two who had probable lymphedema praecox. In three of these patients (Cases 1, 3 and 4), administration of chlorothiazide in doses of 0.5 gm. twice daily was resumed a few weeks after the end of the treatment period and after the edema had recurred. The medication was continued for eight months. During this time, edema was minimal or absent at each of several periodic examinations in all three patients and untoward effects did not occur as the result of the prolonged administration of chlorothiazide.

The effects of chlorothiazide on the edema of the eight patients who had chronic venous insufficiency were variable and in general somewhat disappointing (Table II). As a general appraisal, the results were good in two patients, fair in three and poor in three. It will be noted that discrepancies occur in the estimations of change in the degree of pitting and of the changes in weight and girth in some of these patients. This could be explained by the fact that the estimations of pitting were made in the morning and the measurements of weight and girth in the evening. It is well known that the edema associated with chronic venous insufficiency fluctuates considerably during a twenty-four-hour period, usually increasing progressively during the day and disappearing partially or completely during recumbency at night. All the patients in this group were at least moderately active during the day throughout this study.

TABLE II. EFFECT OF CHLOROTHIAZIDE ON CHRONIC VENOUS INSUFFICIENCY OF LOWER EXTREMITIES

Case	Age, Years	Sex	Grade of Pitting Edema		Mean Weight Change During Treatment, Pounds	Mean Change in Circumference, Inches	
			Before Treatment	During Treatment		Calf	Ankle

12	87	M	2	1+	+0.7	+0.6	+0.1

TABLE III. EFFECT OF CHLOROTHIAZIDE ON IDIOPATHIC SEDENTARY EDEMA

Case	Age, Years	Sex	Grade of Pitting Edema		Mean Weight Change During Treatment, Pounds	Mean Change in Circumference, Inches	
			Before Treatment	During Treatment		Calf	Ankle
13	77	F	2+	1+	−4.2	−0.4	—
14	73	F	2+	2	−6.2	−0.3	−0.3
15	65	F	2	0	−3.0	−0.5	−1.9
16	47	F	3	3	−3.5	−0.5	0
17	72	F	2+	1−	−4.0	−0.3	−1.0
18	81	F	3+	1−	−2.2	−1.4	−1.7
19	79	M	2	1+	−2.2	−0.2	−0.6
20	61	M	2+	1−	−0.8	−0.2	−0.5

The effects of chlorothiazide on the edema of the eight patients having idiopathic sedentary edema were also variable (Table III). All these patients demonstrated some mean loss of weight during the period of treatment, but the loss of weight frequently did not correlate with the change in edema. Some discrepancies were noted in the change of the degree of pitting and reduction in girth of the limbs, which again might be explained by the difference in time of day when these two determinations were made. In general, three of these patients had a very good response, two had moderate results and three had a poor response. This rather pronounced variability of response may indicate that there were factors other

than dependency and physical inactivity that caused the edema in these patients and that varied among the different patients in this group.

chlorothiazide for periods of two to three weeks, and the effect was judged on the basis of decrease in pitting on pressure, change in weight and

*Not done in Case 6.

Determinations of serum sodium and potassium were made on nineteen of the twenty patients in this study during the control period and at the end of the treatment period. Although the majority of patients had some reduction in sodium and potassium during the treatment period as compared with the control period, the reductions were minimal in many and the values actually increased in some (Table IV). In a few patients, the values decreased slightly below the normal range, but none of the patients manifested any clinical symptoms or signs that could be attributed to hyponatremia or hypokalemia. No correlation could be established between the pretreatment values for sodium and potassium or the change in these values during treatment and the cause of the edema or its response to chlorothiazide. Other studies have shown that serum sodium and potassium may or may not decrease in patients treated with this drug, and our studies would confirm the advisability of periodic checks of these electrolytes in all patients who receive chlorothiazide for prolonged periods. It has been shown that the administration of 1 gm. of potassium chloride with each dose of 0.5 gm. of chlorothiazide will prevent any hypokalemia or hypochloremia that might be induced by the chlorothiazide.

Summary

Twenty patients with edema of the lower extremities due to local causes were treated with chlorothiazide. Four patients with chronic lymphedema of moderate degree all had good results from the treatment, and three of these again had similar results when treatment was resumed later and continued for eight months. Results of treatment with chlorothiazide in eight patients with edema caused by chronic venous insufficiency were variable, being good in two, fair in three and poor in three. Results of treatment were also variable among eight patients who had idiopathic sedentary edema associated with prolonged daily sitting and physical inactivity. The results in this group were very good in three patients, moderate in two and poor in three.

Physical Therapy in the General Practitioner's Office

GORDON M. MARTIN, M.D.
Rochester, Minnesota

With such equipment as a couple of plastic wastebaskets, clothesline, dime-store pulley, heat bulbs in photoflood clamp, simple heat cradles and sandbags, the general practitioner can handle many of the physical-therapy needs of his patients. This article tells how to utilize such inexpensive material for successful office physiatrics.

EFFECTIVE physical therapy can and should be provided in general office practice. However, to date it has been neglected in many places. Why? In order to answer this question, several other questions need to be considered:

1. Can a busy general physician effectively provide physical therapy for his patients? Yes, if he wants to.

2. Can anything be accomplished if no trained physical therapist is available? Yes, a physician can be a good therapist.

3. How much expensive apparatus is necessary? None.

4. Can a patient be taught to do his own physical therapy? Yes, practical home treatment can be learned through simple instructions consisting primarily of actually showing how.

A closer look at the answers to these questions should prove helpful.

Some Common Indications

Approximately 12 per cent of patients examined and treated in general practice have musculoskeletal problems that should benefit by physical therapy. Physical treatment is now recognized as standard procedure and essential in the management of such conditions as stiff and painful shoulder, sprains and strains, degenerative disease of the joint, whiplash injuries, rheumatoid arthritis, protruded-disk syndromes, residuals of hemiplegia, and static and postural backache. Present-day methods and high standards of medical practice, now routine in the medical centers, are being made available by the general practitioner to patients in smaller hospitals and the general office, and physical therapy should be included.

Know-How for the Physician

A primary requisite for successful office physical therapy is good common sense plus an understanding of the basic principles of body mechanics, therapeutic exercise, the use of assistive devices, and simple methods of applying heat. Sources of such information are readily available to the physician and include: (1) outstanding short courses on physical medicine and rehabilitation given frequently at the Center for Continuation Study at the University of Minnesota, (2) scientific sessions of the Section on Physical Medicine at the annual meeting of the American Medical Association, (3) articles in the *Journal of the American Medical Association,* MINNESOTA MEDICINE, *GP* and other journals, (4) special booklets such as the new *Strike Back at Stroke,*[1] which can be useful to both physician and patient, (5) scientific exhibits at the state and national medical meetings, and (6) informal conferences with physiatrists, who are always eager to help any physician interested in physical therapy.

Read at the Eighth Annual Refresher of the Minnesota Academy of General Practice, Rochester, Minnesota, October 21, 1958.

From the Section of Physical Medicine and Rehabilitation, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

With a limited amount of special study, some extra reading, and an interest in making practical application of biomechanical and physiologic knowledge of the musculoskeletal system, a physician can function as a fairly good physiatrist and a more than adequate physical therapist when the need arises.

Fig. 1. A 250-watt reflector heat bulb with photoflood clamp attachment.

Some Basic Equipment

In the third question it was categorically stated that no expensive apparatus is necessary for general office physical therapy. Although manufacturers of physical therapy apparatus and their sales staff may serve as useful sources of basic information, one must remember that any big profits they may make must come from the sale of expensive equipment. Thus, they prefer selling a $900 diathermy machine to selling a $30 heat lamp. Likewise, a $1,600 exercise table with variable weights, pulleys and counterbalances intrigues the salesmen more than a simple powderboard and a set of sandbags.

Simple and inexpensive sources of heat for analgesic and vasodilating effects that can be used in the office or home include:

1. A 250-watt reflector heat bulb with a photoflood clamp attachment, for heating a small area (Fig. 1).
2. A baker or heat cradle with eight or ten 60 to 100-watt bulbs as a source of infrared or heat energy, which is useful for treating a lumbar strain or a condition of the lower extremities (Fig. 2). These sources of radiant heat are preferred over the heating pad, which is a common source of first and second-degree burns.
3. Contrast baths for the hands and feet, which require, at most, a couple of plastic wastebaskets, a bath thermometer (to insure having hot water at 110° F. and cold water at 60 to 65° F.) and a time schedule as indicated in Figure 3. These are useful for patients with arthritic disease, sprains and strains.
4. Hot moist packs. These may be a satisfactory source of local heat for office use.

Obviously, almost any amount can be spent on therapeutic heating devices, but one should remember that good physical therapy can be provided without diathermy and ultrasonic machines. Likewise, expensive electrical nerve and muscle stimulators are rarely used. For the occasional patient with Bell's palsy or peripheral-nerve injuries, a small battery stimulator providing manually interrupted direct-current impulses for use in the office and home is available (Fig. 4).[3] Generally, in office physical therapy the application of heat is merely a means to an end, and often the more important part of physical therapy is proper therapeutic exercise, which may be required to improve range of motion, muscular strength or co-ordination.

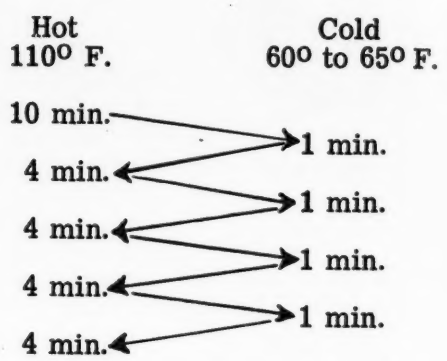

Fig. 3. Temperature and time schedule for contrast bath.

What to Do and How to Do It

Effective physical therapy in the general medical office requires a minimal amount of simple equipment, some basic knowledge of and interest in physical treatment, and a little time actually spent in "show how" for the patient.

Periarthritis or adhesive capsulitis of the shoulder, whether it has followed acute bursitis, trauma or myocardial infarction, or is of unknown cause, should be treated with a correct program of therapeutic exercise in order to increase range of

motion, maintain proper use of the shoulder musculature, and prevent development of a completely frozen shoulder. X-ray therapy, injections of hydrocortisone, and various forms of diathermy have their place but are of less importance than an adequate program of mobilization exercises. These patients rapidly develop many substitute motions, or else completely neglect to use the entire upper extremity and shoulder girdle.

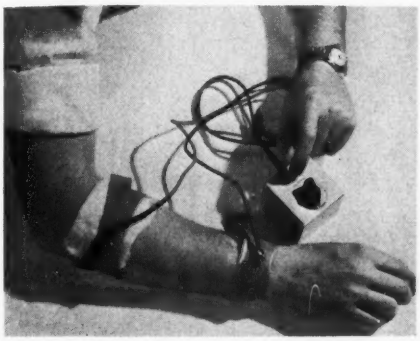

Fig. 4. Battery stimulator for home or office use.

The patient with moderate limitation of motion should be taught to do active exercise three or four times daily through the three primary shoulder motions, namely forward flexion in the sagittal plane, abduction of the arm in the frontal plane, and internal and external rotation with the arm abducted 30 to 60 degrees from the side. The patient should be carefully shown the proper way to do rotation with the scapula and shoulder girdle as fixed as possible against the bed or against the wall. He should learn the feel of this exercise when done correctly on the normal side in contrast to the side with the limited motion. The familiar wall-climbing (finger-ladder) exercise should be used for both flexion and abduction of the shoulder.

A simple and effective device that should be rigged up in the office is the overhead pulley arrangement; ordinary clothesline rope and a single, dime-store pulley may be used (Fig. 5). The patient should be taught to stretch the arm not only into abduction but also into flexion and to practice both internal and external rotation, the normal arm being used as the assistive force in all these maneuvers.

Degenerative disease of the knee joint presents a number of problems that require careful consideration. The mechanisms of wear and tear on a joint should be explained to the patient before he is instructed in the essential measures for protection of the joint. Besides the usual need for

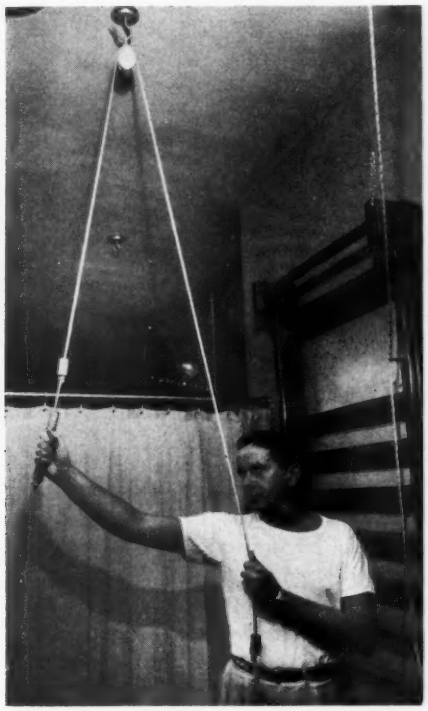

Fig. 5. Overhead pulley for shoulder-mobilization exercises.

reduction of weight and limitation of activity, the patient should be carefully taught how to maintain or increase the strength of the quadriceps femoris muscle. Atrophy with weakness of the quadriceps is an extremely common finding in degenerative disease of the knee joint, often becoming so marked as to be a major factor in the patient's disability, which is manifested by difficulty in climbing stairs and in getting in and out of chairs.[3] Heat and massage alone are of little value for patients whose pain occurs only during weight-bearing activities.

The best way to increase strength of the quadriceps is to teach the patient a definite procedure for doing progressive resistance exercises regularly at home. Simple sandbags can be made up at home and hung over the ankle (Fig. 6). With a set of these available in the office, the physician can help the patient determine what weights he can carry at his first exercise periods and then he

can be instructed in increasing the amount of weight at intervals of one week (Fig. 7). Essentially normal quadriceps power will increase stability of the knee and decrease both discomfort and disability.

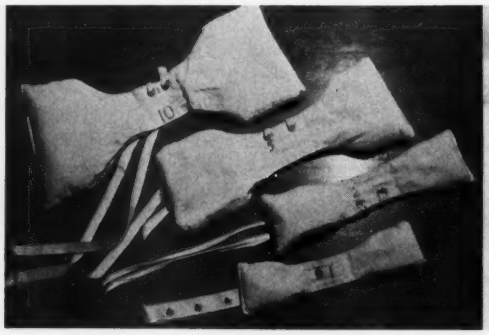

Fig. 6. One, 2, 5 and 10-pound sandbags for resistive exercises.

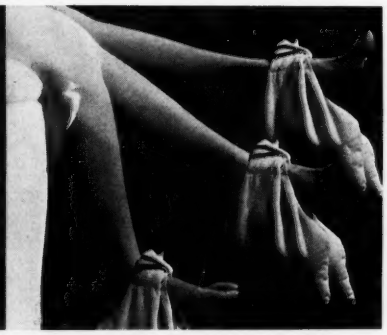

Fig. 7. Sandbag being used for strengthening quadriceps femoris.

Several techniques are available for doing progressive resistance exercises. The DeLorme technique and the Oxford technique use thirty contractions at each exercise period. The basic weight is called "the ten repetition maximum" which is the maximal weight the patient can lift ten times to a position of full extension without stopping. Approximately three-fourths and one-half of this basic weight are then used in groups of ten contractions at each exercise period. Occasionally, such a program may have to be modified to ten or fifteen contractions at each period; or possibly isometric contractions, with resistance, will prove more effective and be better tolerated than carrying the weights through an arc of 90 degrees.

Degenerating weight-bearing joints should, in many instances, be protected from maximal weight-bearing by the use of a cane or crutches. The patient must understand the reasons for using the cane or crutches and may have to be assured repeatedly that cane or crutches should not be considered stigmas of progressive invalidism. Correct fitting of these aids should be the responsibility of the physician. Not one patient in ten who is merely told to use a cane for a painful knee or ankle will find one of the correct size or will use it correctly. When the physician has prescribed the use of a cane for protection of one lower extremity, almost without exception the patient should be taught to use the cane in the opposite hand, with the height adjusted so that the elbow is flexed about 30 degrees when the shoulders are level. The patient should be instructed to keep the cane close to the body and swing it forward with the involved extremity. From time to time the patient should check his own gait by walking toward a full-length mirror in order to see that the shoulders are kept level, the involved leg vertical and not abducted, and the cane close to the body.

The proper fitting of crutches can best be done with a pair of adjustable crutches, which should always be kept handy in the office. Crutches of proper length come to 1 fingerbreadth below the axilla in the normal position, with the crutches about 8 inches lateral from the feet. The hand grip should be adjusted to such a height that the elbow is flexed about 30 degrees (Fig. 8).

In walking with crutches the patient must be taught to bear his weight on his hands, not letting the shoulders hang on the crutches or hike up to a level with the ears. The most satisfactory gait for a patient with degenerative disease of one knee or hip joint is the three-point gait with part of the weight being borne on the involved leg. In this gait the patient moves both crutches ahead simultaneously with the involved leg. Then with the crutches placed on the ground in line with the foot, the greatest part of the weight is transmitted through the arms to the crutches while the involved leg is in contact with the floor and while the good leg swings forward. In this gait the patient should be taught to move the hip, knee and foot of the involved leg in a normal walking pattern. Initial training for a few minutes is much simpler than attempting to correct bad habits in a patient who has tried to master crutch-walking by the trial-and-error method.

If the degenerative changes are bilateral, a two-point alternate crutch gait will permit some reduction in weight-bearing on both lower extremi-

ties. In the two-point gait, the patient is instructed to move the opposite crutch and leg simultaneously and proceed in a normal walking pattern.

Fig. 8. Faulty body mechanics and faulty crutch-walking result from incorrectly fitted crutches. From left to right: crutches too long, crutches too short, and crutches of correct length.

Patients with severe degenerative disease of the joint who are not candidates for any surgical correction and who may require prolonged use of crutches may be much happier with the short, aluminum, German crutches, which are lighter and less cumbersome than the wooden ones.

Some patients with severe degenerative disease of the joint or other permanent disabilities and chronic disease may need advice and guidance of the physician in seeking a new and more suitable occupation. If this cannot be handled easily by the local physician and local agencies, the physician should see that the patient is properly referred to one of the six offices of the state vocational rehabilitation association.

Electronic St. Vitus Dance

The present typically American promotional craze involves vibrating, gyrating, rocking or rolling cushions, chairs, couches, tables, and mattresses—available either in heated or unheated models. "Effortless exercise" for weight reduction, relaxation, and improvement of muscle and tissue tone is a major theme of the advertising.

Suggestions as to beneficial effects of these contrivances in arthritis, rheumatism, heart disease, backache and other troubles are often included in the salesman's "spiel," but not in the printed literature. No scientific evidence that is convincing to discerning physicians has yet appeared in support of these claims.

The public is being duped and attempts are being made to involve physicians both directly and indirectly in some of the promotional schemes. Shall we be made a party to these schemes? No, let's not! Although it is unlikely that any of us will knowingly lend direct support to the schemes or schemers, we must avoid even the indirect support that is inherent in thoughtless, vague or implied approval of these contrivances, which essentially are therapeutically worthless and, for some patients, potentially hazardous.

The Hennepin Counterin

A. B. ROSENFIELD, M.D., M.P.H.
Minneapolis, Minnesota

Director, Division of Special Services and Acting Chief of Section of Maternal and Child Health, Minnesota Department of Health.

THE Minnesota Maternal Mortality Study is a joint study of the Minnesota State Medical Association and the Minnesota Department of Health in co-operation with the Department of Obstetrics of the University of Minnesota. It was first established in 1941 on the basis of recommendations of the Minnesota Obstetrical and Gynecological Society. It is carried out through personal visits to the attending physicians, consultants, and hospitals by obstetrician-investigators who obtain all pertinent data and records. As a result of its successful operation and because of its effectiveness and acceptance by physicians and hospitals, the Minnesota Department of Health, in 1951, proposed a neonatal mortality study.

The approach, however, could not be the same because of the difference in the number of deaths involved. Whereas in the maternal mortality study not more than fifty to sixty annual deaths occurred, including nonobstetrical deaths which are a part of the study, there are some 1,400 neonatal plus 1,200 fetal deaths annually in Minnesota. A state-wide study would thus constitute a rather formidable task.

Furthermore, clinical records in rural hospitals are frequently scanty and limited and autopsies are less frequent. It was, therefore, decided that a pilot study in one large metropolitan area was advisable. After the pilot study had demonstrated its value it was planned to extend the study to other areas in the state.

Hennepin County, which includes the City of Minneapolis, was selected for the pilot study because it has a limited number of neonatal deaths and yet has approximately one-fourth of all Minnesota births and neonatal deaths and would constitute an adequate sample. It has more complete clinical records and has a higher percentage of autopsies. There are fourteen hospitals with maternity departments serving both the metropolitan and rural areas, and a hospital council representing these hospitals. Moreover, it is a convenient and easily accessible area since the State Department of Health is located on the University Campus in Minneapolis and necessary services and facilities would be readily available.

The proposal was submitted to the Child Health Committee of the Minnesota State Medical Association and after approval, to the council of this association, the Hennepin County Medical Society, the Northwest Pediatric Society and the Minne-

Presented at Institute on Perinatal Casualties, University of Minnesota Center for Continuation Study, December 9, 1958.

unterinatal Mortality Study

● The American Medical Association has stated that the goal of perinatal casualty studies is "to improve the production of normal human beings by the elimination of needless deaths and damage during the process of reproduction." This report describes the objectives, approaches, the modus operandi, and the results. These experiences should stimulate the further development of similar studies throughout Minnesota.

apolis Hospital Council. Hennepin County Medical Society and the Northwest Pediatric Society each appointed three members and the Minneapolis Hospital Council appointed one hospital administrator to the proposed committee. Along with representatives from the Section of Maternal and Child Health of the State Health Department and the professors of pediatrics and pathology of the University of Minnesota, these constituted the nucleus of the study committee.

Other interested groups were contacted and agreed to help sponsor the proposed study. The Hennepin County neonatal mortality study began on January 1, 1952 as a cooperative undertaking of the Hennepin County Medical Society, Minneapolis Pediatric Society, Minneapolis Obstetrical Society, Minneapolis Chapter of the American Academy of General Practice, Minneapolis Health Department, Minneapolis Hospital Council, departments of pediatrics and pathology of the University of Minnesota Medical School, and the Minnesota Department of Health.

The neonatal mortality study committee has consisted of or now consists of the following: Drs. William H. Anderson, Eldon B. Berglund, William Bevis, Joel G. Brunson, Eunice A. Davis, James R. Dawson, E. J. Diefenbach, Claude J. Ehrenberg, S. Feinberg, Aaron Friedell, Evelyn E. Hartman, Frederick H. Lott, N. H. Lufkin, George Lund, Irvine McQuarrie, E. C. Maeder, E. S. Platou, Richard Raile, H. R. Ransom, L. F. Richdorf, A. B. Rosenfield, S. S. Scherling, Robert A. Ulstrom, L. W. Wannamaker, Mr. Russell Nye, Administrator at Northwestern Hospital, and Mr. Thomas Cook, Executive Secretary of the Hennepin County Medical Society. The membership has thus included pediatricians, obstetricians, general practitioners, pathologists, public health physicians, an anesthesiologist, a radiologist and a hospital administrator. The chairman and secretary are elected by the committee. Dr. Richdorf, chairman and chief of the Section of Maternal and Child Health of the State Department of Health, serves as secretary. One of the obstetricians on the committee is also a member of the maternal mortality committee and thereby provides a liaison between the two study groups.

In general, the objective of the study is to reduce to a minimum the preventable factors which are associated with neonatal mortality by a detailed study of each death, including management of the pregnancy, labor and delivery, management

of the newborn, nursery procedures, and the adequacy of facilities, records, and autopsies.

More specifically, the committee—

1. Considers the clinical history, physical findings, laboratory procedures, the course of events, and the diagnosis, in relation to autopsy findings.
2. Rates responsibility—
   Was it a pediatric or obstetric death?
   Was it preventable, nonpreventable, or unclassifiable?
   Was there adequate prenatal care?
   Were obstetric and pediatric care proper and adequate?
   Were hospital facilities adequate?
   Was the autopsy adequate?
   Was physician, hospital or family at fault?
3. Judges adequacy of records, autopsies, facilities and services.
4. Points out findings and inadequacies and makes suggestions for reducing preventable factors by an educational program—
   through hospital staff meetings
   at medical society meetings
   through medical journals and bulletins
   through other educational approaches
   at undergraduate and postgraduate levels.

It was estimated that there were approximately 385 neonatal and 300 fetal deaths per year in Hennepin County. It was agreed to limit the study to neonatal deaths, defined as deaths under twenty-eight days of life, for a period of one year following which the committee would decide, on the basis of acceptance and accomplishments, whether or not it should be continued for a further limited period or indefinitely. The question of including fetal deaths was also to be determined at this time. At the end of the first year of operation the committee agreed to continue the study for a period of five years and to include fetal deaths at a later date during this period of study.

From 1952 through 1954 the study included an analysis of the deaths of liveborn infants of more than twenty weeks' gestation who failed to survive the first twenty-eight days after birth. Since January 1, 1955, it has also included fetal deaths of more than twenty weeks' gestation, and the name was therefore changed from "neonatal" to the more inclusive term, "perinatal." Minnesota law requires reporting of live births and fetal deaths of more than twenty weeks' gestation and therefore those under twenty weeks of gestation are not included.

The committee agreed that each participating hospital staff should appoint a hospital liaison committee consisting of an obstetrician, a pediatrician and a pathologist, or physicians with special interest in this problem, to act as the liaison group between the hospital, the record librarian and the neonatal mortality study committee, and to be responsible for the completion of the study report forms. Committee members met with the various hospital staffs to explain the method of operation. The proposed study and the appointment of a liaison committee were approved by the staffs of all hospitals. The hospital liaison committees, directly or through their record librarians, submit the required data for each perinatal death to the secretary of the study committee. To make the reporting as complete as possible, copies of all fetal and neonatal death certificates are prepared by the Minneapolis Health Department and mailed to the secretary monthly. The certificates are matched with the report forms received from each hospital and monthly reminders are sent to hospitals indicating the specific cases on which information has not as yet been submitted. Every effort is made to obtain complete voluntary reporting.

The Perinatal Mortality Study Committee has developed a questionnaire study form which is distributed to all the hospitals. The liaison committee in each hospital is responsible for obtaining the required data on each local perinatal death. This is done with the assistance of the hospital record librarians and, if necessary, of the attending physicians. These report forms are filled in as soon as possible after the hospital clinical record of the case is complete. They are then submitted to the study committee. When the data submitted are not sufficient for committee analysis, personal visits are made to the hospital for additional data. Committee members are on the staff of many of the participating hospitals but not all hospitals are represented. The report form lists the data, the name of the patient, the physician and the hospital on a detachable tab which is removed in the office of the secretary of the study committee. A code letter for the hospital and a code number for the patient are placed on the form and on the autopsy report before they are reviewed by the committee. To assure complete anonymity, the coded tabs are retained in a confidential file at the state department of health. A Minnesota statute makes it a misdemeanor to reveal this confidential material and protects all parties involved by not allowing it to be admitted

in any court or before any other tribunal, board, or other agency.

The full committee meets in closed session about once a month. In the interim a small subcommittee meets to screen the deaths. A summary of the pertinent data from each case is presented to committee members at the meeting. For controversial and complicated cases, the complete data are presented to the committee for consideration. Each case is discussed in an objective and impartial manner. Responsibility is classified as obstetric, pediatric, medical, or assigned to the hospital. Each case is judged preventable, nonpreventable, or unclassifiable. The specific factors in each case are listed as (1) inadequate prenatal care, (2) family at fault, (3) physician's error in judgment, (4) physician's error in technique, (5) intercurrent disease, (6) unavoidable disaster, or (7) inadequate autopsy. When the case is unclassifiable, the reasons for this fact are listed—for example, "inadequate records" or "inadequate autopsy." All the pertinent data and the committee findings and classifications are transferred to McBee Keysort system punch cards for ease in tabulation.

Necessary funds for the study are provided by the State Health Department. This includes the services of a staff pediatrician who devotes about one-half time to the study, report forms and supplies, cost of mailing notices of meetings and correspondence, and general administrative and clerical costs.

Information gained through the county-wide study of perinatal deaths is used as basis for recommendations and suggestions in the committee's educational program, which includes frequent reports and special articles in the *Bulletin of the Hennepin County Medical Society*. Annual reports in MINNESOTA MEDICINE include rather extensive statistical analyses, summaries of case histories, and comments of the committee on deaths considered to have been preventable. Committee findings are also disseminated at medical society and hospital staff meetings. Contact with under-

graduate and graduate teaching is facilitated by the fact that the committee includes representatives of the Medical School's departments of pediatrics and pathology.

TABLE IV. AUTOPSIES BY INFANTS' BIRTH WEIGHT
Hennepin County Perinatal Mortality Study
1952-1955

Weight	Number and Percentage of Infants Autopsied							
	1952		1953		1954		1955	
	Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent
(Premature) 2500 grams or less	122/238	51.0	140/270	52.0	134/215	62.3	163/261	62.5
(Full-term) over 2500 grams	74/95	77.9	95/109	87.1	75/85	88.2	87/97	89.7
Total	196/333	59.0	235/379	62.0	209/300	69.7	250/358	69.8

A few selected tables of the statistical data of the study are briefly reviewed. Table I gives the neonatal and fetal deaths and rates for Hennepin County from 1940 through 1957.

Analysis of the data for the first four years (1952-1955) in Table II shows that 72 per cent of the 1370 neonatal deaths were infants weighing 2,500 grams or less. Of these premature infants, 67 per cent died during the first twenty-four hours after birth and 83 per cent during the first forty-eight hours. Of all the neonatal deaths three-fourths occurred during the first two days and 92 per cent during the first week of life.

Table III, which presents the causes of neonatal deaths shows that abnormal pulmonary ventilation, which includes immaturity unqualified, atelectasis and hyaline membrane disease, accounted for 61 per cent of the deaths. Three-fourths of the premature infants were in this category in contrast to 20 per cent of the full-term infants. Congenital anomalies were the second cause of death, responsible for 16.6 per cent. Among the full-term infants anomalies were the leading cause, responsible for 37 per cent of full-term deaths but for only 8.5 per cent of the premature infants.

TABLE V. RH DETERMINATIONS BY YEARS
Hennepin County Perinatal Mortality Study
1952-1955

Year	Per Cent of Rh Determinations Done
1952	70.0
1953	68.3
1954	71.6
1955	80.8

TABLE VI. RATING OF NEONATAL DEATHS
Hennepin County Perinatal Mortality Study
1952-1955

Classification	2500 Gm. and Under	Over 2500 Gm.	Total Number	Per Cent of 1370 Neonatal Deaths
Preventability				
I. Preventable	43	58	101	7.4
II. Non-preventable	912	297	1209	88.2
III. Unclassifiable	29	31	60	4.4
Responsibility				
A. Obstetrical	810	132	942	68.8
B. Pediatric	169	257	426	31.1
C. Inadequate hospital facilities	0	1	1	.1
D. Medical	30	13	43	3.1
Factors involved				
1. Inadequate prenatal care	20	5	25	1.8
2. Family at fault	106	44	150	11.0
3. M.D. error of judgment	45	54	99	7.2
4. M.D. error of technique	6	9	15	1.1
5. Intercurrent disease	20	17	37	2.7
6. Unavoidable disaster	890	282	1172	85.6

Table IV shows that during the first year of the study the autopsy rate on all neonatal deaths was 59 per cent (51 per cent for prematures and 77.9 per cent for full-term infants); by the fourth year (1955) the over-all rate had increased to 69.8 per cent (62.5 per cent for premature and 89.7 per cent for full-term infants).

There has been a gradual increase in Rh determinations from 70 per cent in 1952 to almost 81 per cent in 1955, shown in Table V.

Table VI summarizes the findings relative to preventability and responsibility for the first four

years of the study. It will be noted that 101 (7.4 per cent) of the 1370 neonatal deaths were judged preventable. While only 4.4 per cent of the premature neonatal deaths were rated as preventable, 15 per cent of the full-term neonatal deaths were considered preventable. An additional 12.8 per cent had inadequate prenatal care or the family failed to seek early prenatal care. However, on the basis of individual preventable factors rather than preventability of death the percentage is considerably higher. For example, Table VII shows that in 1955, out of 358 neonatal deaths there were ninety-one preventable factors or 25.4 per cent of the deaths. These included inadequate or delayed diagnosis and/or treatment, delayed, inadequate or no consultation and failure of family to seek or to follow medical advice.

TABLE VII. PREVENTABLE FACTORS IN 358 NEONATAL DEATHS
Hennepin County Perinatal Mortality Study, 1955

Factor	Number
Inadequate and/or delayed diagnosis	23
Inadequate and/or delayed treatment	37
Delayed or no consultation	7
Family did not seek and/or follow medical advice	24
Total	91 (25.4%)

For the first year of the perinatal study (1955) there are data on 255 fetal deaths. Table VIII presents the mothers' ages by weight of the fetus in grams. Table IX gives the types of delivery. Table X shows the maternal factors associated with the fetal deaths. There was a history of previous premature birth in thirty-four cases and of previous abortion in fifty-eight instances, occurring in 36 per cent of the fetal deaths. Among the maternal factors were abruptic placenta in sixty-two cases and antenatal bleeding of undetermined cause in thirty-five cases, totaling more than one-third of the fetal deaths (38 per cent). Toxemia occurred in twenty-nine, maternal diabetes in ten and prolapsed cord in nine cases.

Almost one-third (30 per cent) of the fetuses were macerated (Table XI). Congenital anomalies were found in thirty-three or 13 per cent, erythroblastosis fetalis in thirteen, and birth trauma and/or intracranial hemorrhage in fifteen cases.

TABLE VIII. MOTHERS' AGES IN 255 FETAL DEATHS BY BIRTH WEIGHT
Hennepin County Perinatal Mortality Study, 1955

Ages of Mothers	Weight of Infants in Grams					Total	Per Cent
	1000 and Less	1001-1500	1501-2000	2001-2500	Over 2500

35-39	8	4	4	7	17	40	15.7
40 and over	4	1	1	9	2	17	6.7
Total	64	31	30	39	91	255	100.0

TABLE IX. TYPES OF DELIVERY OF 255 FETAL DEATHS BY BIRTH WEIGHT
Hennepin County Perinatal Mortality Study, 1955

Type of Delivery	Weight of Infant in Grams					Total	Per Cent
	1000 or Less	1001-1500	1501-2000	2001-2500	Over 2500		
Cephalic	42	24	22	25	72	185	72.6
Breech	22	8	6	3	11	50	19.6
Cesarean section	1	1	2	5	11	20	7.8
Total	65	33	30	33	94	255	100.0

The first year of the study of fetal deaths shows that only 50 per cent had autopsies (Table XII). This is similar to the first year of the neonatal mortality study with 59 per cent autopsies and 51 per cent for those less than 2,500 grams in weight.

There has been a gradual decrease in the neonatal and fetal death rate as shown in Table I, but the study cannot take credit for this reduction because of the multiple factors involved. Credit can be taken for an increase in prenatal care, in Rh determinations, in an increase in the autopsy rate, in more complete clinical records and in the quality of care.

Some problems have been encountered in the study. The study was designed to be carried out

on the basis of voluntary reporting and submission of pertinent data by each hospital. In general, there was excellent cooperation but occasionally there was some difficulty in obtaining reports; more often the record was incomplete or inadequate. Some committee members have lost interest or have become too busy to devote the necessary time to the study. Periodic reports of the findings of the study, including serious errors of omission or commission, are published. But physicians do not receive individual reports of the findings or the criticisms of the committee. Thus, they are unaware of the conclusions of the committee as to their handling of individual cases. Both the maternal and the perinatal mortality committees use the educational approach rather than a punitive approach. Therefore, physicians should be informed of the committee's critical conclusions if the study is to be effective. The maternal mortality committee sends such reports to the attending physician as well as to the consultant concerned.

Since the Hennepin County Medical Society is the chief sponsor of the study and since with but one exception representatives of all participating groups are also members of this Society, suggested changes in procedure to make the study more effective were transmitted to the medical society for its consideration and action. The Board of Directors of the Society approved the following recommendations:

1. For the purpose of professional betterment, correspondence or personal visits may be undertaken between the perinatal mortality study committee and those physicians deemed by the study committee to have been guilty of serious errors of omission or commission.
2. Each hospital participating in the study should be invited to have a representative on the study committee.
3. Representatives of the State Board of Health may visit personally with attending physicians or the hospitals involved for the purpose of supplementing incomplete or inadequate records.

As to its acceptance and the advisability of continuing the study which is now in its fifth

TABLE X. MATERNAL FACTORS IN 255 FETAL DEATHS BY BIRTH WEIGHT
Hennepin County Perinatal Mortality Study, 1955

Over 2500	57	22.3
Total	129	50.4

year, on September 30, 1958, the Board of Directors of Hennepin County Medical Society approved the indefinite continuation of the perinatal mortality study with authority to the committee to select and appoint physicians with special interest in perinatal mortality.

Before concluding, it might be of interest to briefly discuss the differences in the approach used in our maternal and perinatal studies. The maternal mortality study employs a trained obstetrician-investigator who visits the hospital, abstracts the hospital record, and interviews key hospital personnel who were involved in the care of the patient. He visits the attending physician as well as any consultants concerned and completes a sixteen-page questionnaire. He thus has all the data available, including original records, laboratory reports, x-rays and tissue specimens or slides. A complete summary in chronological order is prepared for the consideration of the study committee. After action by the committee, a copy of the summary is mailed to the physician and consultant. It includes the decision of the committee as to the correct diagnosis, adequacy of medical and hospital care and laboratory procedures, completeness of records, necessity for consultation and the competency of the consultant, completeness of autopsy, as well as the preventability of the death and the preventable factors. This approach has been quite effective and well received. The study is so thoroughly carried out that it is actually an excellent postgraduate course in obstetrics and no one is willing to leave the committee voluntarily. As a result, it has gradually enlarged in size by the addition of new members to represent all parts of the state.

But the maternal mortality study involves only some fifty deaths. The perinatal study, in our largest metropolitan county, involves about 700 fetal and neonatal deaths and includes hundreds of physicians. To attempt to obtain such detailed and complete data on perinatal deaths would require a staff of investigators and a tremendous amount of time. To carry out interviews in an objective and impartial manner with the large number of physicians who provide obstetrical and pediatric care in Hennepin County would be quite difficult. To attempt to avoid criticism, directly or indirectly, would be almost impossible in many cases and would result in resistance, possible resentment and lack of cooperation on the part of the physicians concerned. The obstetrician-investigator for the maternal mortality study is instructed to obtain all pertinent information but he is not to express an opinion or any criticism of the handling of a case. He informs the physican that all conclusions are determined by the committee after careful consideration of all data and that a copy of the report will be mailed to him and his consultant.

It should be obvious that we feel that the approach used in the maternal mortality study is our most effective means of studying and reducing mortality. Nevertheless, in spite of the limitations outlined above, members of the Hennepin County Perinatal Mortality Study Committee believe that definite progress has been made and will continue to be made in the improvement of care in the perinatal period. The philosophy of the study and its objectives have been quite generally accepted. The committee has had the cooperation of the practicing physicians, the pathologists and the hospitals, in its efforts to reduce perinatal mortality.

One of the by-products of the pilot study has been the establishment of local studies in several out-state hospitals. Neonatal studies have been carried out at Willmar and Virginia, and for the past year a perinatal mortality study has been in progress in Duluth. A similar study is under consideration in Ramsey County which includes the City of Saint Paul. These studies are in cooperation with the State Department of Health, making it possible for local hospital studies to have the benefit of the statute which makes such studies confidential and protects all parties involved by not permitting such data to be admitted in court.

In conclusion, the perinatal mortality study committee has attempted to determine the primary cause of death in each case and to classify these causes in as meaningful a way as possible. It has emphasized the importance of autopsies to determine the actual cause of death, and it has been encouraged by the increase in the autopsy rate. In its progress reports and annual analyses the committee has endeavored to inform physicians of its findings, including errors of omission or commission, and has recommended means of reducing the recurrence of preventable factors. It feels that this educational approach must ultimately help to improve the quality of obstetric and pediatric care with a resulting decrease in mortality and morbidity.

Methamphetamine Sulfate in the Treatment of Nocturnal Epileptic Seizures

• Nocturnal epileptic seizures are controlled remarkably by methamphetamine sulfate given to patients just before bedtime. Patients with additional diurnal seizures were less well helped; in fact a few were worsened.

JOHN LOGOTHETIS, M.D.
Minneapolis, Minnesota

PREVIOUSLY, we reported[1] a preliminary study on the use of Desoxyn® (methamphetamine sulfate) in a number of epileptic subjects. It was our conclusion that patients with nocturnal seizures, receiving the drug at bedtime, responded well to the therapy. This was in contrast to the cases where the patient experienced diurnal seizures; they manifested an aggravation in seizure frequency when this drug was administered during the day.

TABLE II. SUMMARY OF RESULTS WITH DESOXYN® IN NOCTURNAL EPILEPSY
Forty-one Patients

Result	No.	Degree of Control
Patients improved	28	2—complete control 6—80-90% seizure control 13—50-79% seizure control 7—20-49% seizure control
Patients with little or no change	9	6—no change 3—up to 19% seizure control
Patients aggravated	4	

The present study, which represents a continuation of the above work, further confirms our original impression on the effect of methamphetamine sulfate in nocturnal seizures.

Materials and Methods

A total of forty-one epileptic patients with nocturnal seizures were treated with methamphetamine sulfate (Desoxyn®) from three to fifty-four months (average 18.8 months) in the seizure clinic of the University of Minnesota Hospitals. All patients had had convulsions for many years with no evidence of progressive neurologic disease. The average number of seizures per month was 4.2 (0.2—thirty) while the number of nocturnal seizures ranged between 50 and 100 per cent of the total

From the Division of Neurology, University of Minnesota Medical School, Minneapolis.
This work was aided by a grant from the Teagle Foundation.
Desoxyn® is a product of Abbott Laboratories, North Chicago, Illinois.

number of spells. There were twenty men and twenty-one women in the group. The ages ranged from sixteen to sixty-eight. The spells were mostly major motor and, to a lesser extent, other types. Laboratory studies, including skull roentgenograms, spinal fluid, and routine hematologic examinations, gave values within normal limits. All patients except one had negative blood serology. Glucose tolerance tests were performed in 70 per cent of the patients and were found to be normal except in two patients where the curves were diabetic. In two-thirds of the cases, pneumoencephalography was performed. This test was abnormal in only five patients, exhibiting a mild to moderate degree of ventricular enlargement. Electroencephalograms were performed in thirty-eight of the forty-one patients. All but five were abnormal. Methamphetamine sulfate in a dosage of 5 to 10 mg. given at bedtime, was added to the total daily medication which the patients were previously receiving. Although, in many instances, the amount of the previous drug was reduced, no attempt (except in two cases) was made to remove it completely.

The total number of seizures during methamphetamine sulfate trial was compared to the number of seizures reported during the same length of time prior to the institution of treatment with the drug. In seventeen of the forty-one patients, the seizure frequency during Desoxyn therapy was also compared to the frequency of spells over an equivalent period of time after this therapy was discontinued. In the evaluation of our results the total number of spells (both nocturnal and diurnal, if any) was considered.

Results

The results of this study are listed in Table I where a detailed record is given relating the effect of the drug to the frequency of seizures in the individual patient. In addition, the electroencephalographic findings, any change in the previous medication, and the number of nocturnal seizures are given for comparative purposes. Our studies in-

dicate (Tables I and II) that twenty-eight of the forty-one patients studied showed an improvement in the frequency of the seizures; nine exhibited no significant change; while four had an increase in seizures. Among the twenty-eight patients who showed improvement, in nine the previous anticonvulsive medication was reduced by at least one-third during the methamphetamine sulfate therapy. Four of these patients continued to show a good response, three had no significant change whereas two manifested an increase in the frequency of their daytime attacks. In two patients, exhibiting 90 per cent or more of their spells at night, the previous medication was completely discontinued and the patients obtained a better seizure control on the methamphetamine, alone, than on their previous medication. The more frequent the diurnal seizures were, in addition to the nocturnal ones, the less responsive the patients were to the methamphetamine therapy (Table III).

Among thirty-three patients exhibiting abnormal electroencephalograms, twenty-five revealed non-focal patterns characterized by more or less paroxysmal bilateral changes. In over half of the cases, these were synchronous in appearance.

Discussion

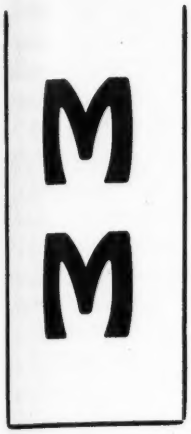
The observations presented above suggest that the usage of methamphetamine sulfate and probably other amphetamines should be considered as an adjunct in the management of seizure patients manifesting nocturnal attacks. A report in the literature of one patient with nocturnal seizures controlled with benzedrine[2] is in accordance with our observation. Since our preliminary work[1] suggested an aggravation of diurnal seizures by methamphetamine, no attempt was made either to give this drug during the day or to withdraw the previous medication, except in two cases. It was found of advantage to administer the drug just prior to the time the patient falls asleep. It has been our experience that patients with nocturnal seizures rarely complain of any disturbances in the pattern of sleep if the drug is administered in this manner.

The electroencephalographic changes in the majority of our patients, characterized by bilateral paroxysmal patterns, suggest the presence of deep-seated epileptogenic lesions discharging to both hemispheres. We were unable, however, to distinguish any electrical abnormality pathognomonic for nocturnal epilepsy.

The mechanism by which amphetamines are effective in treating nocturnal seizures, as well as the possible pathophysiologic patterns involved in nocturnal epilepsy, were discussed extensively in our preliminary report. As more recent studies[3] indicate, the site of action of amphetamines appears to be at the brain stem reticular activating system. It is possible, therefor, that the indirectly-induced dissynchronization of electrocortical activity by stimulation of the activating reticular system by the amphetamines, produces a lighter sleep and consequently maintenance of cortical inhibition over subcortically-arising epileptic discharges.

TABLE III. EFFECT OF DESOXYN® ACCORDING TO PROPORTION OF NOCTURNAL SEIZURES
Forty-one Patients

Nocturnal Spells Per Cent	Patients Improved Per Cent
90-100	66
75-89	70
50-74	43



Summary

1. Methamphetamine sulfate in a dosage of 5 to 10 mg. at bedtime, was found useful in the treatment of nocturnal seizures in twenty-eight of forty-one patients suffering from epilepsy.

2. The electroencephalographic patterns in these patients suggest that subcortical epileptic foci may be responsible for nocturnal epilepsy. Methamphetamine probably derives its anticonvulsive effect in nocturnal spells through its effect at the brain stem reticular activating system.

● Are our courts today placing the medical profession in a position of constant defense and insecurity? If the lay public can file suit for "assault and battery" as well as "unauthorized treatment," and if a lay jury can decide a case on the basis of *res ipsa loquitor*, then as the author states, it is time for our legislature to enact some changes in the present laws and their interpretation.

When a physician is afraid to employ certain useful techniques because of the possibility of malpractice litigation, then it is apparent that the patients will be the losers.

The author also lists the six principal causes of lawsuits against physicians.

A Medical Legal Problem

BURR B. MARKHAM, Esq.
Minneapolis, Minnesota

Member of the Minnesota Bar

IN 1905, the Supreme Court of the State of Minnesota decided the case of *Mohr vs. Williams*. From time immemorial suits against physicians had been predicated on the legal theory of negligence. The term negligence as applied to a physician was referred to as malpractice. As a general proposition to prove that a physician was guilty of malpractice, it was necessary to establish by competent evidence that the physician failed to use the standard of care ordinarily exercised by physicians in the community in which he prac-

Address presented before the Minnesota Academy of General Practice, Minneapolis, October 22, 1958.

ticed. This rule came into being in the English Common Law and received the studied opinions of many competent jurists.

It has been contended by certain members of the legal profession that this rule was too harsh inasmuch as many deserving plaintiffs, who had been damaged by negligent treatment, were unable legally to establish their claim because of the reluctance of physicians to testify that the act of the defendant physician was not in conformity with the standards of care in the community. As a consequence, the legal profession began seeking means of permitting lay juries to pass upon the conduct of a physician based upon result, rather than theories of law which had proved sound throughout the centuries.

Any unauthorized touching of a person's body constitutes assault and battery in legal contemplation. There are exceptions to this rule, such as an emergency medical procedure. In the *Mohr* case the physician had diagnosed difficulty in the patients right ear. In surgery it was discovered the trouble was in the left ear. The doctor proceeded surgically to repair the difficulty. Following the operation the patient sued the doctor on the theory of "assault and battery" contending that she had not consented to the operation upon her left ear. It was apparent no authorization for an operation upon the left ear had been obtained, hence, a lay jury was permitted to consider the question of damages for assault and battery. The result was a verdict for the plaintiff in the sum of $14,322.50. The Supreme Court set the verdict aside on the ground that it appeared the jury had been influenced by passion and prejudice and directed a second trial. This resulted in a verdict of $3,500.00. The trial court set this verdict aside as excessive. An appeal was taken and a third trial ordered. At this point, the harassed physician settled the matter rather than incur further legal expense and exposure. All this for having performed a successful and beneficial operation.

In analyzing the defendant's position, it would appear he could only have escaped his predicament by awakening the patient from the anesthetic during the course of the operation. After determining that the patient was in full possession of her faculties, he then would have had to secure her consent to the procedure performed.

In a well considered article by Professor Allan H. McCoid, entitled "A Re-Appraisal of Liability for Unauthorized Medical Treatment," 41 *Minnesota Law Review* (1957), he analyzes the ridiculousness of the "assault and battery" or "unauthorized medical treatment" theory and suggests that a physician's responsibility to his patient should still be tested by the rule of malpractice.

The Minnesota court, however, in applying the principle of assault and battery or unauthorized operation theory, opened the door for the application of liability without fault. It would seem that the *Mohr vs. Williams* case did not create much legal significance in this state. However, Oklahoma adopted the principle quoting the *Mohr vs. Williams* case as authority. Other states followed. When the rule was advocated in North Carolina, quoting the *Mohr vs. Williams* case as authority, the Supreme Court of that state rejected it, stating that to adopt such a rule would require the physician to maintain a set of well organized plans and specifications authorized by his patient and filed in his office safe for every medical procedure.

In 1955, Helmer and Nita Bang sued Dr. Frederic Foley, the eminent St. Paul urologist, for alleged damages resulting from an unauthorized operation by Dr. Foley. The plaintiff Helmer Bang sought general damages of $100,000 and $50,000 in punitive damages. The wife Nita Bang sought $25,000 general damages and $15,000 in punitive damages. It was claimed that Dr. Foley had without authority performed a vasectomy. At the first trial plaintiff, in response to cross-examination, admitted that he had authorized Dr. Foley *"to do everything that was necessary in order to treat his urinary retention difficulties."* The trial court directed a verdict in favor of Dr. Foley on the theory that this general consent gave the physician implied authority to perform an operation as in his good medical judgment was necessary to effect a cure of the patient's condition. The Supreme Court reversed the case and held that under the record of the first trial, it would appear a better rule should be adopted and that in such circumstances, the following rule should be applied:

> Where alternative medical procedures exist the physician shall inform the patient of such alternatives and permit him to make the choice.

In other words, a general consent from the patient to do what in the physician's judgment is necessary will not protect the physician from liability.

It may be argued there is a saving clause in the

opinion, wherein the court stated that for purposes of the case at bar the rule should be applied. However, on the second trial of the *Foley* case we had an opportunity to try and apply the rule. Upon re-trial, plaintiff contended he had not even consented to an operation upon his prostate. When he talked to Dr. Foley it was agreed that Dr. Foley should do everything that was necessary, but he, the patient, was talking about his bladder and not his valuable prostate gland! Fortunately, the lay jury exonerated Dr. Foley. Nevertheless, the jury was permitted to pass on whether there was consent to operate upon the prostate gland as well as the question of unauthorized severance of the vas deferens.

Imagine a physician describing to his patient the alternatives of every medical procedure. How can the physician make the patient understand all of the alternative procedures? In a rather humorous manner, I think this situation is best described by a letter I received from Dr. Foley after he had attempted to analyze the application of this rule as he saw it from the physician's viewpoint.

Protection of himself against the evils of this decision will require the physician to explain to the patient every fact and circumstance surrounding his pathologic condition and the actions the physician may take as indicated by them for the patient's welfare.

Innumerable facts and circumstances of this sort and the common practice of physicians in dealing with them point out the fallacy of the rule which this decision establishes. In the presence of this rule and with thought for his own safety the physician would have to have a preoperative discussion and obtain multiple permissions for operation which would go like this:

2:00 P.M. I should explain to you, patient, that your symptoms are due primarily to your prostate gland and are of a mechanical nature, that is mechanical obstruction to your passage of urine through the prostate gland.

However, other structures of your genito-urinary system besides your prostate and conditions other than mechanical obstruction to urination are involved in your trouble and any operation on your genito-urinary system which may be employed to give relief of your trouble. You must understand that the proposed operation will be an operation on your genito-urinary system, not merely on your prostate gland.

For example, your water passage, or urethra as it is called, far beyond and below your prostate will be stretched, dilated with dilating instruments as a part of the contemplated operation on your genito-urinary system. This dilatation of your urethra may lead to periurethral abscess formation with febrile illness. It is a bad postoperative complication and may be serious or even fatal.

The contemplated operation is called transurethral resection. You may be cared for by another form of operation: suprapubic prostatectomy. In performance of that operation instrumental dilation of your urethra would not be done and would avoid the possible ill effects of that. But the consensus of opinion is that transurethral resection, even accompanied by instrumental dilatation of the urethra, is a safer method and carries less risk to life and risk of serious complications and is the safest form of operation.

I should explain to you that your bladder connects with your prostate gland and that in removing the obstructing portion of your prostate, a part of your bladder floor will also be removed.

Almost invariably an obstructing prostate is infected. Spread of that infection is the greatest danger attending operation. One avenue of infection spread is through the ducts or cords going from the prostate to the testicles. Spread of infection through these ducts or cords may lead to inflammation and abscess formation in the testicles and could result in loss or one or both of your testicles. Loss of your testicles would not only render you sterile, but also would leave you with no sexual desire, no erection of your penis, and incapable of performing the sexual act. That would cause your wife loss of your "consortium."

To avoid such disasters the result of this operation on the genito-urinary system one step in the operation is to sever the ducts connecting the prostate to the testicles. This makes impossible spread of infection from prostate to testicles with these disasterous results.

Division of these ducts or "cutting the cords" as this part of the operation is called, in non-technical language, has no unfavorable effect on your sexual desire or ability to perform the sexual act and will not rob your wife of your "consortium." The only effect of cutting your cords will be to prevent spread of infection to your testicles. If "cutting your cords" were not combined with excision of your prostate it would also have the effect of making you infertile (sterile). Since excising your prostate will make you sterile, it cannot be said that "cutting your cords" is responsible for it.

In considering infertility (sterility) which can be effected by "cutting the cords" you must bear in mind the fact that excising the obstructing tissue of your prostate—the chief feature of this operation on your genito-urinary system—will by itself render you sterile without "cutting your cords." So even without "cutting your cords" the excising of the obstructing part of your prostate will make you sterile and incapable of rendering pregnant your wife or any other woman.

How excision of the obstructing portion of the prostate causes sterility is a simple matter. This excision of tissue from the prostate destroys the internal sphincter of the bladder which closes off the bladder from the water passage going downward through the substance of the prostate gland. At climax of the sexual act, in the male, this internal sphincter muscle contracts tightly closing the communication between bladder and water passage. This closure causes the ejected seminal fluid to pass outward through the water passage, or urethra as it is called, into the wife's vagina. When the internal sphincter has been

destroyed by excision of the obstructing prostatic tissue there is free communication which cannot be closed off because of the destroyed sphincter between bladder and water passage. As a result the ejected seminal fluid instead of going outward into the wife's vagina, goes inward up into the bladder. The seminal fluid thus ejected into the bladder will be seen floating in the urine first voided from the bladder following the sexual act.

Following this operation you, and perhaps your wife too, will be conscious of the fact that climax of your sexual act is not accompanied by ejection of seminal fluid from your penis into her vagina. Sometimes this observation is disturbing and alarming to both husband and wife. Very frequently husbands who have had this operation, question me about this effect of the procedure. I explain the situation to them as I have explained it to you and point out that it is a normal and always produced effect of the operation. That satisfies them and quiets the disturbance and alarm they and their wives may have felt. I might also explain to you, patient, that this absence of "ejaculate" as it is called, has nothing to do with "cutting the cords" going to the testicles for the seminal fluid is not formed by the testicles. It is a secretion of the epithelial cells of the seminal vesicles, two glands which lie under the bladder and connect with the water passage by way of ducts. These ducts go through the substance of the prostate to reach the water passage. The seminal fluid secreted in this way accumulates in the seminal vesicles and is stored there between performances of the sexual act. At climax of the man's sexual act, the seminal vesicles contract and the seminal fluid which has accumulated in them is forcefully ejected into the water passage. At the same time the internal sphincter muscle contracts tightly and closes off the bladder from the water passage which forces the seminal fluid to go outward. A prostate operation destroys the internal sphincter. This leaves the water passage in open communication with the bladder. This communication is the path of least resistance and the seminal fluid passes upward into the bladder instead of going outward into the wife's or somebody's vagina.

Two other features of this situation must be explained to you if you are to have a clear understanding of what is involved, and give me permission to do all the procedures which are required for your proper surgical care, avoidance of complications and safety.

The first of these is the pubic and scrotal hair of your genital region which will be in the field of operation. It is not possible to sterilize this hair to make the field of operation free of germs. Not sterilized genital hair might lead to infection, just as your spermatic cords might transmit infection from your prostate to your testicles if I failed to "cut your cords." So as part of the operation on your genito-urinary system your genital hair will be cut along with "cutting your cords." Some men consider this "hair cut" a disfigurement, find it distressing and complain of it while their wives may feel it impairs "consortium."

And finally there is your blood. Your blood is no more an integral part of your genito-urinary system than any other part of your body. In spite of that it is an integral part of this operation on your genito-urinary system, just as your "cords" and genital hair are parts of it. Even in the absence of any emergency made by fall of blood pressure or other indication of surgical shock, blood transfusion is almost regularly employed in an operation of this sort on the genito-urinary system as a safety measure to avoid postoperative complications, just as the genital hair and "cords are cut" for this purpose.

Say, by the way, patient, are you a Jehovah's Witness? If you are and I gave you a blood transfusion without your permission, you would probably sue me on the ground of assault. Members of the Jehovah's Witness cult will not permit themselves to be transfused with blood—would prefer to die.

There should be clear understanding between us in all of these matters. I should know to which church you belong and I should know that you clearly understand all steps of the genito-urinary operation to be performed and should have your permission to perform them so that performance as parts of this long standardized and practiced genito-urinary operation for relief of prostatic obstruction will not be regarded as an assault upon your person.

So, patient, it is up to you to decide if you wish to be operated upon, what form of operation you wish to have, and if you wish to have me do all I can to avoid possible complications—such as loss of both of your testicles. There is no emergency or urgency about this and it is up to you to decide what form of operation you want and whether or not you wish to be operated upon at all. The trouble you have is not of grave nature, formidable, or critical, and will not be fatal within the immediately foreseeable future. So if you wish not to be operated upon you may do so safely—there is no emergency about it.

6:30 P.M. Sorry, patient, it is after six o'clock and there are still ten patients waiting to see me.

So now, look: here is a form for you to sign giving me permission to make this operation on your genito-urinary system including particularly your permission to give you: (1) a prostatic resection, (2) a hair cut, (3) a cord cut, (4) a partial excision of your bladder floor, (5) a dilatation of your urethra, (6) a blood transfusion.

But before you sign, you must realize that the cords, the water passage below your prostate, the bladder floor, the genital hair and your blood are not parts of your prostate gland which is making your trouble.

On the form I have given you, you will note that below your signature giving the required permission is a statement above my signature in which I agree to make this operation on your genito-urinary system in accordance with the standardized form of operation long practiced and not fail to carry out any part of that procedure which would be for your benefit and safety and for which you have given specific permissions.

While you are looking through this form, I hope you will excuse me while I tell the patients in the reception room, who have been waiting there during most of the afternoon while I have been talking to you, to go home and come back tomorrow.

Needless to say, doctors themselves do not agree upon medical procedures and a strict application

of the rule would substitute the patient's judgment for that of the physician. Moreover, I wonder if the patient wants to know the mortality statistics and all the details of every medical procedure. If such a rule is to be followed, how can 170,000 doctors treat 170 million people? Most of their time would be spent in educating their patients on the intricate details of medical science.

I think the following example demonstrates the necessity for abolishing the "assault and battery" rule: Plaintiff fell off a farm wagon in 1944, and struck the back of his head, neck and shoulders on the wagon. No serious consequences appeared at the time, but about a year later periodic headaches set in which had become constant and unbearable by October 1948. After consulting a doctor in the city where he lived, plaintiff on November 30, 1948, went to an Ohio hospital for examination and treatment, being placed under the care of the defendant Dr. A. After two days of conservative treatment, which proved ineffectual, Dr. A performed a spinal column operation on December 3. At this operation Dr. A was assisted by Dr. B, who in Dr. A's absence had charge of plaintiff from that time on, and he examined him at various times and made notations in the hospital records. The operation was a cervical laminectomy. The laminectomy consisted of the removal of the spinus processes of the first four cervical vertebrae to give access to the spinal canal.

Plaintiff's recovery from this operation was uneventful and he was discharged from the hospital on December 13 and returned to his home under instructions to get up and around a few minutes each day. However, on December 25 his headaches returned and a week later, on December 31, he came back to the hospital for further observation and treatment. On January 1, 1949, Dr. B, in the course of making his regular round of visits, came to plaintiff's bed and after questioning him as to what had happened while he was at home, asked him if he would sit up, first in bed, then on the edge of the bed, which he did. Dr. B then asked him to turn his head from side to side, but plaintiff complained that this movement caused him pain, whereupon Dr. B remarking that he could surely turn his head more than three-fourths of an inch, put his hands on the side of plaintiff's head and turned it from side to side twelve or fifteen times, this being in spite of plaintiff's protests and resistance.

Dr. B then said, "I want to see his reaction on his feet," and so the doctor helped him on with his slippers and robe, walking back of plaintiff and cupping his hands in plaintiff's hands. When plaintiff still continued to resist, Dr. B said, "You just don't seem to want to try to get well. Don't you want to get well?" In this fashion Dr. B got plaintiff out into the hall and they walked down the hall some thirty feet. Dr. B then took his patient over next to the wall saying, "I want you to walk. You keep trying to walk." Thereupon plaintiff claims that Dr. B left him, and his wife and another woman had to lead plaintiff back to his room and to bed. The hospital records contain the following notes by Dr. B relative to this occurrence:

> The patient has not been out of bed since he left the hospital. Neurological essentially negative except for surgical analgesia as noted. History obtained from wife revealed patient had a very good friend operated on in Indianapolis, Indiana, who died a few hours post-operative; since then patient has continually cited severity of his operation. States that he has pain in the analgesic area but yet unable to feel a pin. He resents close questioning as to his condition and states he cannot walk. I urged him to get out of bed and he exhibited a pseudo-ataxia and then became quite angry because he had to get out of bed. The nurse observed him while I answered a phone call and he told her he was going to get out of here because he could not understand his condition. With that remark the ataxia disappeared and he ambled over to his bed. Impression—conversion hysteria.

The foregoing occurrence furnished the entire basis of plaintiff's $128,000 suit for malpractice against Drs. A and B.

In his argument to the jury, counsel for plaintiff frankly stated:

> I should like to state now once and for all and without the slightest equivocation, the essence of our case is assault and battery. Mr. Horn, defense counsel, says that we have not proved negligence. We have not attempted to prove negligence. We do not take the position that this is a negligence case. Whatever malpractice was committed here we insist was a malpractice by reason of doing a completely unauthorized act not a negligent act, an unauthorized act.

Plaintiff's contentions were:

1. Dr. B's treatment of his patient, the plaintiff, on the occasion in question, was not consented to by the plaintiff, but on the contrary was opposed and resisted by him; hence he was unauthorized and in law amounted to assault and battery.

2. Consequently, there having been willful assault by Dr. B, medical evidence was unnecessary and the nature of the occurrence was such that lay testimony was sufficient for a jury of laymen to find Dr. B guilty of malpractice.

Defendant's contentions were:

1. By voluntarily becoming a patient at the hospital the plaintiff gave his consent not only to the operation performed on him, but also to any and all postoperative treatment which the hospital doctors, including Dr. B, in good faith, deemed necessary for his recovery. For this reason Dr. B's treatment on the occasion in question was not unauthorized nor did it amount to an assault and battery; it had been consented to in advance and his consent lasted as long as he remained a patient at the hospital;

2. Except in rare cases malpractice must be established by medical evidence and not by lay testimony and while there exists an exception that under certain circumstances lay testimony is sufficient, the case at bar falls in the rule and not within the exception.

The trial court directed a verdict in favor of both defendants. In doing so the trial court made these comments:

> But here is a doctor who has to find out just how much flexibility the patient has, whether he actually can stand or not, or whether or not he can walk, so he moves the man's neck around a little to see how much numbness there may be there or somewhere else. So he tries to help the gentleman to move his head a little, and he didn't like it and he protested and he hollered. Well, I suppose that his head had stayed still in the three weeks that he had been home except once a day he probably got up. Can I say as a layman, that his present condition and everything he has gone through, was caused directly by or would not have happened except for what Dr. B had done this day?
>
> Now, that is exactly what is expected of these trial jurors as laymen, to say without medical help or without medical testimony, from their own knowledge and experience, and the average of them would not have any more than I would have.
>
> Now then, suppose that your little child is sick with constipation, and you say, "Willy, step up here and get a dose of castor oil." Willy says, "I don't want it." And you say, "You have to take it." So you hold his nose and give him the tablespoon of castor oil and Willy screams. Is that assault and battery? Am I supposed to let this go to a jury of twelve laymen who will say that the doctor who tried to help him on this occasion by moving his head and getting him to his feet is the cause of it all and he ought to pay for it all?

However, the Court of Appeals reversed the judgment of the trial court as to Dr. B stating:

> It is the unanimous opinion of the members of this court that plaintiff's evidence discloses a course of conduct upon this occasion by defendant Dr. B constituting a technical assault and battery upon plaintiff, a very sick and weak man, with resulting injuries. It is a contention of defendant's counsel that the patient, by entering the hospital and submitting to treatment, gave implied consent to anything which might occur, such as the conduct here considered.
>
> This rule has no application to the facts and circumstances here indicated by the evidence presented by the plaintiff in the instant case, where the patient and his wife protested vigorously against the conduct of the physician. In the absence of evidence to the contrary, the vigorous but unavailing protests of plaintiff and his wife, constituted an express refutation taking precedence over any implications arising from the fact plaintiff submitted to treatment by the hospital. Further, it is our view that the question of consent, either express or implied, under the circumstances was a question of fact for the jury under proper instruction.
>
> In our opinion, upon plaintiff's evidence, the treatment accorded the plaintiff upon this occasion by the physician was unauthorized thus bringing the case within the exception to the general rule that expert medical testimony is necessary to support a case against a physician for negligence.

As was observed by the trial court, the practice of medicine is replete with instances of these alleged assaults. One has but to sit in a dentist's or a doctor's waiting room, or walk down a hospital corridor to hear the protestations of the patients against the often painful but usually necessary treatment of the doctor attempting to help the patient beyond immediate pain to final recovery. If the natural reticence and understandable objections of the patient to every necessary but painful treatment adhered to by the doctor is to convert treatment properly deemed necessary by the attending physician into a technical assault and battery, actionable in law *per se*, without regard to negligence, then the practice of medicine will have to be drastically curtailed. Yet, this is what the decision of the Court of Appeals clearly implies, for it renders the doctor liable without fault for the technical assault thus committed and renders him an insurer of all subsequent events the lay jurors may decide they think resulted from such treatment. If this decision is to be the law, then the doctor will have to forego many vitally necessary treatments at the first painful outcry from the patient. Surely our courts must learn to take a more realistic view of the medical facts of life. If

the progress of medical science is not to be seriously curtailed, I submit that our courts must take a more realistic view of the situation and require medical proof of negligent treatment if the ultimate interests of the public are to be served and medical science advanced.

Another example of the liability without fault theory in malpractice cases is the so-called *res ipsa loquitur* doctrine. Notably this doctrine has been adopted by the state of California in certain situations where a physician's negligence is claimed. As a general statement, the law of California in adopting this doctrine permits lay juries to pass upon the liability of a physician where a bad result has occurred purely upon the basis of the result. The theory of *res ipsa loquitur* is that where the factors which result in the harm are under the sole control of the defendant, it is permissible to allow a lay jury to decide whether or not the harm resulted from negligence by the defendant. The Supreme Court of California has said that they adopt this rule in specified cases because of the reluctance of physicians to testify against each other.

In an effort to cure what has been so loosely described as the physician's closed-mouth policy, certain states, notably California, have adopted liberal policies to permit lay juries to pass upon a physician's responsibility to his patient where there has been a bad result. The abhorrence and sympathy for the patient's condition strongly influences the laymen, and injustice must follow. Here is an example.

This case arose out of the following circumstances: The plaintiff, a fifty-four-year-old man employed as a stock clerk, had suffered intermittent claudication in the calves of both legs for about a year. He had been attended by a specialist in internal medicine who treated him conservatively with drugs intended to improve circulation. When the patient did not respond, he was referred by the internist to the defendant doctor, a specialist in vascular surgery. The defendant doctor examined the patient and found complete absence of pulsations from the femorals down. The patient had all the other signs of an obstruction in his aorta and the defendant doctor recommended that he enter the defendant hospital for further studies to determine if an operation could be performed to improve the patient's condition. The plaintiff claims he understood he was entering the hospital merely for some routine x-rays. Up to this point, the patient had no sensory or motor nerve disturbances.

The patient entered the hospital on January 6, 1954. He was examined by a resident in surgery and x-rays of the chest and abdomen were taken with barium swallow. The next day, the patient was scheduled for translumbar aortography, but this was postponed until the afternoon of January 8, 1954. The patient was taken at that time to the x-ray department. The defendant doctor was present at the very start of the procedure, but did not participate in it. He left the room after a minute or two. The patient was given an anesthetic by an anesthetist. A resident in surgery inserted a 16-gauge needle into the aorta in the usual manner without difficulty. Thirty cc. of sodium urikon were injected through the needle and a series of films taken. Upon examination of these films, with the patient still under anesthesia, the resident in surgery, after conferring with the radiologist, decided that an additional run should be made in an attempt to visualize collateral circulation lower down on the body. An additional injection of 20 cc. was made without changing the position of the needle. The patient was returned to his room, apparently in good condition. The next morning about 5:00 a.m. it was found that the patient was completely paralyzed from the umbilicus down. He had a transverse myelitis which unquestionably was permanent in nature. Complete paralysis of the lower extremities, bowels and bladder were present. The patient was a permanent paraplegic.

The plaintiff's first complaints at the trial were that the defendant doctor himself did not perform the procedure as the patient had expected, but that it was done by an allegedly inexperienced resident. (In fact, the resident had considerable experience, but this was difficult to establish.) The patient complained that he was not advised in advance of the procedure that there were any risks or dangers attendant to it. There was a claim that 50 cc. of sodium urikon was too much and exceeded the recommended dosage of the manufacturer's brochure, which was 15 cc. He also complained of two runs being taken.

At the trial it was difficult to establish what in fact caused the paralysis, as there is very little in the literature concerning such a complication, although a few have been reported. It was the defendant doctor's opinion, and that of another expert, that there had been an occlusion of the blood supply to the spinal cord which resulted in necrosis of the cord. The third expert, a neurosurgeon, was of the opinion that the complication was due to a toxic reaction to the drug.

At the trial it was demonstrated that the patient would require paraplegic care for the remainder of his life. Plaintiff's expert testified that he had a normal life expectancy of about twenty years. This, of course, was contrary to the findings demonstrated by the aortogram, which showed an almost complete block of the aorta very close to the take-off of the renal arteries.

There was no direct testimony that standard practice was not followed either by the hospital and its employees or by the defendant doctor. An independent medical expert called on behalf of the plaintiff to testify was not permitted to express an opinion on the standard practice in the community in the performance of aortography, on the ground that he was not qualified in the field.

The trial court denied defendants' motions for a nonsuit and directed verdict on the theory that the doctrine of *res ipsa loquitur* was applicable and submitted the

case to the jury on this doctrine. The court did not require proof of negligence by the plaintiff. In applying the doctrine of *res ipsa loquitur* to the case, the trial court instructed the jury that there was a presumption or inference of negligence from the untoward result which it was incumbent upon the defendants to explain away. The trial court's instructions, in effect, made the attending physician responsible for practices without untoward results, even though he was not in attendance at the time.

The jury rendered a verdict in favor of the plaintiff against both defendants in the sum of $250,000. This was reduced by the trial court to approximately $215,000 and the case was appealed by both defendants.

One has to sympathize with the defendant doctor. The risk at $250,000 is too great a one for him to be asked to assume. If this is to become the law, it is apparent that the patients in the progress of medical science—not the doctors—are to be the losers. Under the pressure of such odds, the doctors will simply cease to employ such techniques regardless of their benefit to the patient and regardless of the fact that, statistically, serious complications are rare.

In a discussion of this case, a leading Cleveland orthopedic surgeon stated that the medical profession is already retrenching along this line, foregoing many useful techniques for fear of a court and jury imposing tort liability without fault, and that malpractice litigation is now considered by the medical profession as an occupational hazard so great even as to affect adversely current medical school enrollment.

It has been reported in *Newsweek* magazine of July 11, 1955:

Some five thousand cases are now being tried each year with thousands of other cases settled out of court. Since 1950, one out of every thirty-five doctors insured under the New York State Medical Society's group insurance plan has been sued in the courts for malpractice.

The chairman of the District of Columbia Medical Society Professional Liability Insurance Committee (where recently 115 malpractice cases were pending and the doctors found all group insurance withdrawn from them) states:

Only about one in seven or eight of the District cases shows any voluntary negligence on the doctor's part nonetheless the doctor loses about one in four cases.

Fortunately, our Minnesota courts have refused to adopt the *res ipsa loquitur* theory.

In May of 1957, Arthur Snyder from the Chicago Daily News Service reporting for the American College of Surgeons, stated the following as the principal causes of lawsuits against physicians:

1. Failure of a doctor to call in a consultant when progress is poor.
2. Allowing the patient to become over-optimistic about the outcome.
3. Failure to obtain proper written consent to perform an operation.
4. Critical comments of one physician about the work of another.
5. Failure to obtain understanding with the patient in advance of the cost of care.
6. Failure to have a nurse or other professional attendant in the room during the examination of a woman patient resulting in suits for undue familiarity.

While the patient still respects the doctor's authority, says the College, at the same time today's patients are more knowledgable and sophisticated than were the patients of an earlier generation.

In order to correct the evils of the "assault and battery" or "unauthorized treatment" theory, two courses are open to the medical profession: (1) Legislative enactment and (2) Re-consideration by the Supreme Court.

I suggest the medical profession urge the legislature to adopt the following act:

In the absence of an emergency, any patient, or guardian or parent of an incompetent or minor patient, who shall give a physician or surgeon a general consent in writing to perform medical treatment will be deemed to have authorized such physician or surgeon to do all things necessary which in the judgment of the physician or surgeon are required for the welfare of the patient. Nothing herein stated shall relieve the physician or surgeon from performing the treatment in a skillful manner commensurate with the recognized standard of good medical practice.

As an English court said in 1954:

We should be doing a disservice to the community if we imposed liability on hospitals and doctors for everything that happens to go wrong. Doctors would be led to think more of their own safety than of the good of their patients. Initiative would be stifled and confidence shaken. A proper sense of proportion requires us to have regard to the conditions in which hospitals and doctors work. We must insist on due care for the patient, but we must not condemn as negligence that which is only misadventure. . .

Recurrent Mixed Tumor in the Buccal Mucosa of a Seven-Year-Old Boy

A relatively common tumor made rare because of its location in a child.

MICHAEL J. KOZAK, M.D.
MERRILL D. CHESLER, M.D., F.A.C.S.
Minneapolis, Minnesota

MIXED TUMORS of salivary gland origin have been of particular interest for many years and debate still rages about their origin, degree of malignancy and treatment. These tumors are not common, their incidence being below 1 per cent of hospital admissions, but they occur in a significant number of patients with tumors of the head and neck. They can be classified into those that are definitely benign and those that are definitely malignant, but the largest and the most controversial is the group of mixed tumors which are benign yet may recur after surgical excision and even become malignant. It is not possible to determine microscopically which tumors will recur but the more cellular tumors apparently have more potential in this respect.[1]

The pathogenesis of these tumors has been a controversial subject for many years. At first it was thought that they were purely epithelial in origin. Later the endothelial theory was introduced by Wortman but was soon abandoned and the epithelial theory generally accepted, particularly since the investigations of Kennan and Fry. The great majority of investigators agree

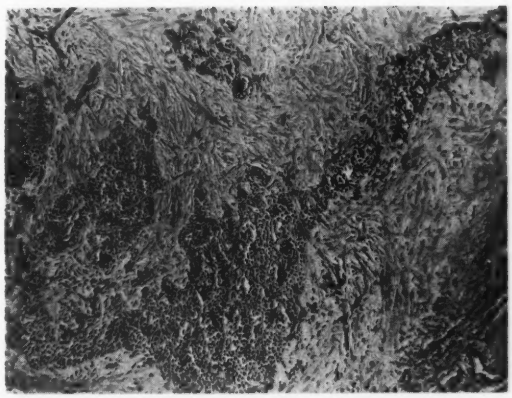

Fig. 1. Photomicrograph taken June 13, 1957. The section is composed of medium-sized epithelial cells arranged in nests and cords with scattered areas of cartilage formation.

that microscopically these tumors are mixed in the sense that they contain both epithelium and connective tissue stroma, the predominant element being the epithelium which appears in the form of interlacing strands, convoluted columns, solid nests, cribiform nests and acini separated by various amounts of fibrillar and myxomatous tissue or hyaline cartilage.

These tumors may be found in various parts of the orofacial region. In most reports, the distribu-

tion is as follows: parotid gland approximately 90 per cent, submaxillary gland 10 per cent, sublingual glands less than 1 per cent, and occasionally they are also found in the lips, cheeks, palate and the floor of the mouth.

The clinical course is variable. In the majority of patients, the history is of a slowly growing or stationary lump. A small percentage of mixed tumors cause some local discomfort, a vague sense of pressure or pain at the tumor site. In the retromandibular tumors, pain may be referred to the ear. Recent reports indicate that the presence of pain as well as rapid growth are indications of possible malignancy. Benign mixed tumors of the parotid gland, even those that reach large size, very seldom cause paralysis of the facial nerve in sharp contrast to what may be expected in cancers.

Despite the fact that these tumors are extremely uncommon in the earlier years of life (being most common in persons between twenty and forty years of age), there are scattered reports of their occurrence in early childhood and infancy. The reports indicate that from 1920 to 1950 there have been 2,309 cases of mixed tumors reported in which the age of the patient was stated. Included in these reports are sixty-six instances of mixed tumors in children.[2]

Following is a case report of possibly the youngest patient ever to have had a mixed tumor of *buccal* salivary gland origin.

Report of a Case

This seven-year-old boy was first seen on July 9, 1957. The history revealed that about eight months prior to examination, his mother had noticed some asymmetry of his face. About June 8, the child complained of a lump in his mouth. Examination by his family physician showed a rounded tumor 2 cm. in diameter in the left cheek. The cervical nodes were normal.

The tumor was excised locally on June 12, 1957, from within the mouth. On gross examination, the specimen consisted of an irregular fleshy tumor nodule 2 x 2 x 1½ cm., and a separate fibrous capsule 3 x 2 cm., and 3 mm. thick. On microscopic examination, the tumor was composed of medium-sized epithelial cells arranged in nests and cords with scattered areas of cartilage formation typical of a mixed tumor. The fibrous membrane was dense connective tissue invaded by nests of tumor cells. The tumor nuclei were slightly larger than usual and showed moderate variation in size and a very occasional mitosis. Because of apparent inadequate removal of the tumor, the child was referred for complete excision.

Examination on July 9, 1957, revealed a 1½ x 2 cm. moderately firm, nontender movable mass medial to the left ramus of the mandible, attached to the buccal mucosa.

Surgery was performed August 9, 1957, under intratracheal anesthesia. The mass was located just posterior to the opening of the Stenson's duct. Excision was performed from within the mouth. At the completion of the dissection, the internal pterygoid and temporalis muscles were exposed as was the coronoid process of the mandible; the excision defect in the buccal mucosa was

Fig. 2. Photomicrograph taken August 9, 1957. This section illustrates a mixed tumor in which the cells are generally quite uniform in size and appearance. In places, there is a tendency to form small ducts, although for the most part the cells are arranged in clusters, nets and solid masses. Cartilage formation is evident.

3 cm. in diameter. The wound was approximately primarily with chromic catgut. The child had a normal postoperative course and was discharged on the fourth postoperative day with the recommendation of frequent follow-up visits to check the possibility of recurrent growth.

Microscopic sections of this excised specimen again revealed a mixed tumor, adequately excised. Examination in January and May 1958 revealed no evidence of local recurrence or involvement of the nodes in the neck.

Conclusion

A case report has been presented of possibly the youngest patient ever to have had a mixed tumor of *buccal* salivary gland origin.

Clinical Psychosomatic Conference

ULCERATIVE COLITIS

A penetrating evaluation of its psychosomatic causes

Editor: HENRY A. JOHNSEN, JR., M.D.

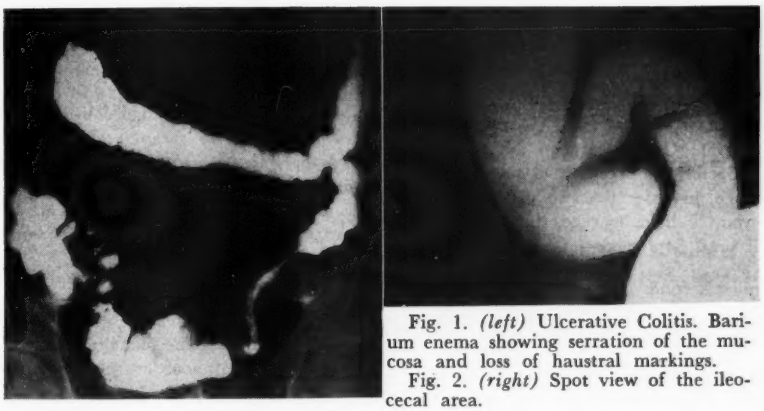

Fig. 1. *(left)* Ulcerative Colitis. Barium enema showing serration of the mucosa and loss of haustral markings.
Fig. 2. *(right)* Spot view of the ileocecal area.

Somatic Evaluation

A white man, aged twenty-seven, a married teacher trainee from south central Minnesota was admitted to the Minneapolis VA Hospital for the first time, complaining of abdominal cramps and diarrhea of twenty days' duration. Previous history revealed that he had been well, except for intermittent headaches as long as he could remember, until one month before admission. At that time he began to note daily frontal headaches of great severity together with increasing weakness, which finally caused him to stop working, ten days after the onset of symptoms. Two days later, his cramps and diarrhea began. He could not tell whether or not his diarrhea was preceded or accompanied by the passage of blood, because he was color blind. One week after the development of diarrhea, he was admitted to his local hospital with a tentative diagnosis of typhoid fever. He remained there for workup until he was tranferred directly to our hospital with the diagnosis of ulcerative colitis. He had lost 20 lbs. during his month-long illness.

Physical examination revealed a well-developed asthenic white man who looked ill. His blood pressure was 96/66 mm. Hg., pulse 100 and regular and his temperature was 100.8 degrees orally. He showed signs of dehydration and weight loss and his breath was foul smelling. There was marked abdominal tenderness in the region of the sigmoid colon. Proctoscopy revealed a thrombosed hemorrhoid and a hemorrhagic denuded area on the lowest valve of Houston. The mucosa was otherwise normal to the 16 cm. level, at which point patchy areas of friable, granular, slightly hemorrhagic mucosa became visible. Ordinary manipulation of the scope revealed that the mucosa was easily traumatized up to the 25 cm. limit and that it bled rather briskly. No polyps were seen. The physical examination was otherwise within normal limits.

Laboratory tests revealed that the hemoglobin varied between 12.0 and 13.0 gm. per cent on seven determinations during his hospitalization. The hematocrit ranged

from 36 to 39 per cent. Similarly, his leukocyte count remained between 5,550 and 8,850 cells per cu. mm., but the differential count revealed more lymphocytes then neutrophils on four occasions. Differential leukocyte counts were otherwise normal. The erythrocyte sedimentation rate gradually fell from an admission value of 71 mm. in one hour (Westergren) to 14 mm. in one hour just before discharge. Stool examinations revealed many pus cells and much mucus but no parasites or ova were found. Fluoroscopy during a barium enema revealed rapid passage of the contrast medium through the entire colon. The terminal ileum was visualized. Tenderness was noted over multiple areas of the colon. The mucous membrane of the cecum and entire colon, except the ascending segment, was serrated, suggesting tiny mucosal ulcerations (Fig. 1). The cecum and ascending colon were contracted and narrowed (Fig. 2). The transverse colon was rigid. The normal haustral markings could not be seen in the transverse, descending and sigmoid colon. No pseudopolyps, fistulae or constricting lesions were seen. The following studies were negative or normal: urinalysis, Venereal Disease Research Laboratory (VDRL) slide test, serum agglutination tests for enteric pathogens, serum albumin, globulin and zinc sulfate turbidity, bromsulphalein (BSP) retention, three blood and stool cultures, direct and indirect Coombs tests and a roentgenogram of the chest.

DR. JOHNSEN: May we have the patient brought in for an interview now?

Interview of Patient

DR. RICHARD MAGRAW (University Consultant in Psychosomatic Medicine): Good afternoon, Mr. A. I'm Dr. Magraw. Your doctor has asked us to review your case in this conference, in order that we may continue to be of help to you. I have learned that you have been relatively well until September—

PATIENT: September second.

DR. MAGRAW: And what did you notice then?

PATIENT: At that time the first thing that happened was that I began to get headaches everyday. Aspirin would relieve it only temporarily, but I managed to keep working.

DR. MAGRAW: What was that headache like?

PATIENT: They were located towards the front of the head, perhaps.

DR. MAGRAW: Well, can you describe the headaches more accurately? There's a lot of room for a description of headaches. Did it come on at any particular time?

PATIENT: Yes. I would not awaken with it, but it would come on an hour or two after starting work. If I continued to work, it would get worse. I think if I would have stayed home in bed, it would have been better.

DR. MAGRAW: What kind of work were you doing at the time?

PATIENT: It wasn't physically hard because I was a college student working in a factory.

DR. MAGRAW: What did you think was the cause of these headaches?

PATIENT: I think I have headaches more frequently than most people, and I attributed them to eyestrain. However I never had them day after day like that before.

DR. MAGRAW: How long did they continue to bother you daily?

PATIENT: For four weeks, until I arrived at this hospital.

DR. MAGRAW: How do you happen to remember the date, September second, so well?

PATIENT: You don't forget this kind of an illness easily.

DR. MAGRAW: What day of the week was September second?

PATIENT: Tuesday.

DR. MAGRAW: And you've been sick ever since?

PATIENT: Yes, I have.

DR. MAGRAW: And what happened next?

PATIENT: On September fourteenth, the day before I was scheduled to resume school, I developed cramps and diarrhea. I went to my family physician who hospitalized me with a diagnosis of possible typhoid fever. I, myself, thought it was a bad attack of stomach flu, because of the headaches, cramps, and diarrhea, but I had never been that sick before.

DR. MAGRAW: What was so bad about this illness?

PATIENT: Well, the fact that I had to go to the bathroom every half hour or so, and kept passing either a loose stool or mucus. I continued to do this through the night. I would estimate that I had to pass a stool at least twelve times in a twenty-four hour period.

DR. MAGRAW: What was the worst part of your illness? Was it the pain?

PATIENT: Yes. The cramps would get worse just before I had a bowel movement.

DR. MAGRAW: Was there any other aspect of this illness that particularly troubled you?

PATIENT: Well, I was very weak, and I lost my appetite at the very beginning of it. I became lethargic and developed a feeling of not wanting to work at all. I lay in bed all day.

DR. MAGRAW: Tell us what happened after you entered the hospital.

PATIENT: Well, of course I didn't get much better there because they weren't treating me for ulcerative colitis. In addition, one of my relatives was not very understanding about the disease. He kept pestering me a

couple of times a day. So I think part of the trouble was psychosomatic, and I think he made the illness worse than it was. I think he made the headaches worse than they otherwise would have been.

DR. MAGRAW: What was his attitude toward your illness?

PATIENT: I think he is sort of a confused individual. I think he was acting under the impression that he was cheering me up. I feel confident that he was making me much worse because as soon as I transferred to this hospital, the headaches disappeared within a couple of days. He is one of these individuals who focuses his life around money. All he would talk about was his money problems, or how he had suffered during illnesses he had had.

DR. MAGRAW: How did that make you feel?—sad?—mad?—anxious?

PATIENT: Well, when I was in the hospital suffering from my own illness, I didn't want to hear anything about anybody else's illness.

DR. MAGRAW: So, how did you feel about this?

PATIENT: Awful.

DR. MAGRAW: Can you use another word? How about those choices I gave you?

PATIENT: Demoralized.

DR. MAGRAW: You're still evading me.

PATIENT: Well, perhaps I felt sad or melancholy.

DR. MAGRAW: Why do you think you got sick when you did?

PATIENT: My doctor says the cause of ulcerative colitis is not known. I was under the impression that all illnesses were caused by microorganisms, but I guess they are not. I suppose nerves or worry might have something to do with it. However, I was married in June of the summer previous to this one and became a father soon thereafter, and that period was, I felt, much harder on me. I felt that if this illness was due solely to nervousness, I would have contracted it then, rather than at this time. I suppose that it could have been building up for a long period of time.

DR. MAGRAW: We don't know what causes ulcerative colitis, but we think that sometimes your state of mind has something to do with it. Have you any idea about what additional factors may have brought on your illness?

PATIENTS I have thought about it and although I have not been consciously aware of increased tension, I was scheduled to begin student-teaching in my last quarter of college, the day after the diarrhea started.

DR. MAGRAW: How are you feeling now? How many stools are you passing now?

PATIENT: I feel as well as I've ever felt. I'm passing about two stools daily now. And they are all solidly formed.

DR. MAGRAW: Do you still have cramps?

PATIENT: Not for a week now.

DR. MAGRAW: When you have these things you describe as cramps, what are they like?

PATIENT: They're across the lower part of the abdomen.

DR. MAGRAW: Are they there all the time?

PATIENT: Well, they are very persistent. Two weeks ago the doctor tried to put me on solid food and I had a cramp that lasted for two and a half days after that.

DR. MAGRAW: How are your spirits now?

PATIENT: Tip-top.

DR. MAGRAW: There are many more things we could go into, but I think this will suffice. Thank you very much.

Discussion of Interview

DR. JOHNSEN: Dr. Magraw, would you comment on the interview?

DR. MAGRAW: Well, we have some kind of an idea about the kind of patient we are dealing with. He seems to be somebody who deals in abstractions. He avoids anything concrete.

In an excellent review of ulcerative colitis, one of the former medical fellows at this institution, Dr. John O'Leary,[1] who is now in practice in Brainerd, Minnesota, emphasized that you can make a history anything you want and that is one of the problems that one gets into in trying to understand what the pathogenesis of this illness is. This man is what the psychiatrists would call somewhat schizoid, because of his interest in dealing in abstractions rather than in any concrete feeling or more realistic appraisal of interpersonal relations. I think that the arithmetic of his first child and his marriage in June of last summer is probably important.

DR. JOHNSEN: Would you give us your clinical impression of the patient? What did you think of his affect? How would you size him up as a person?

DR. MAGRAW: I could sum this up by saying that he looks like a tough nut to crack, because he doesn't have much affect. You don't have much to get hold of. He's an extremely passive person, and one who would be prone to be content with, or in fact insist on, more or less magical or abstract explanations for his own behavior and symptoms.

DR. JOHNSEN: Did he strike you as being a mature person?

DR. MAGRAW: No. The word immature does not have much specificity here. Perhaps it would be better to describe him as being very passive and somewhat effeminate. Effeminate isn't quite the right word. He

might better be described as being "neuter," I guess. He's a very colorless individual. I'm not using these descriptive terms in a disparaging way.

DR. JOHNSEN: Would you describe his tone of voice?

DR. MAGRAW: He didn't flap his vocal cords the way some people do with this personality structure.

DR. JOHNSEN: Would you care to comment on the choice of adjectives he used, and those he failed to use, in describing his feelings during visiting hours, at the time of his first hospitalization?

DR. MAGRAW: He demonstrated an extremely inhibited type of defense against the expression of feeling. This is undoubtedly a fear of anything having to do with aggression or expression of antagonism. Whenever you block off a large segment of your life potential by disavowing any expression of aggression or hostility, you necessarily block off a big segment of your life with it. This man has a sort of over-all inhibition of affect, of feeling. I might guess, from what meagre impressions we can get during this brief interview, that the core of his inhibition is related to any expression of anger.

DR. JOHNSEN: I think the only word that he didn't mention, out of the choices you gave him to describe his reaction, was the word "mad." It is interesting to note that the relative he was talking about was his father who, while visiting the patient in the local hospital, described his own recent bloody prostate operation. I think if that happened to anyone of us, we wouldn't be ashamed to say we were mad.

DR. MAGRAW: Yes, this is part of what I'm talking about when I speak about his capacity to make things abstract. He'd rather talk about "the person" or "that person." Did you notice his very characteristic use of the article "the"? He spoke about "*the* cramps" and "*the* diarrhea." When a patient puts the article in front of a word, it serves a twofold function. It removes it from any blood-and-guts kind of direct level. It's like talking about "the accident" instead of "my stroke." It also has the function of sort of certifying the physical complaint as being objective. It takes the complaint out of the realm of something the patient has to document or prove. It seems to set it up on a pedestal as something that has been proved.

Psychiatric Evaluation

DR. JOHNSEN: It seems appropriate at this time to describe the developmental background of the individual we have interviewed, and to assay some of the resultant characteristics of his personality.

He was born and brought up in the same town whence he comes to us now. No unusual circumstances were associated with his birth, and he was breast-fed, like his brothers. One brother is five years older than he and the other is a year younger than the patient. Of the three, the patient was the only bed-wetter, and remained so until the age of fourteen. Because of the resultant odor, his older brother used to hit him for this. The patient says that when they were children their father used to beat this older brother, who would then take out his feelings by beating up the patient. The patient says that he had no particular talent and, as the middle child, was apparently undistinguished in the family constellation. He distinctly felt rejected by his father and remembers hearing his father express wonder and resentment about the birth of his younger brother since, for economic reasons, the father had particularly tried to avoid this contingency. Since he was born during the depths of the depression, the patient assumes that his father felt this way about him, too. The patient says that he does not bear a strong resemblance to anyone in his family, although he is probably more like his mother.

His parents are still living and are in their sixties. They were divorced three years ago, after many years of bickering, principally over money. Because of this, all of the children "had a hard time." The patient says of his father, "He's the sort of person that builds his whole world around money. Personally, as far as I'm concerned, he's mentally insane. He has an uncontrolled temper. He's extremely nervous and restless. He has a habit of swearing. He used to be doing dishes and singing, and would break out swearing and then go back to singing." He also thinks that his father is a kleptomaniac because he used to take small things from hotels where he stayed. His father is a retired paint salesman. The patient tells of a time when his father was interviewed by a psychiatrist who called him a hopeless case. He says his father hates doctors and has never paid a bill from a physician or hospital.

The patient says that his mother was submissive and "stupid for taking all that. She said a thousand times that she would leave him, but it turned into an empty phrase." He says that in 1948 his mother went back into teaching. In 1955 she divorced his father and moved out of the state because, the patient thinks, she thought his father would be worse than ever after his retirement, with not enough money and too much time on his hands.

Since retirement, his father has stayed at a hotel in town. During the month before the patient's present illness began, his mother returned and sold the family home. He describes his mother as having been very liberal, "maybe too liberal," while he was growing up, inasmuch as "she gave the children everything, to make up for not having a real Dad." However, he states unequivocally that his mother favored his younger brother. This twenty-six-year-old single brother, in the eyes of the patient and his family, was a good scholar and an outstanding student. He finished teachers' college and has been completing his army service. He plans to marry a Korean girl. His older brother distinguished himself in the family by being a good mechanic. This brother is currently being divorced from the same woman for the second time.

After graduating from high school in 1950, the patient entered service and although he admits to being "emotionally disturbed" during basic training, and to hating everything about the army, he does not give the impression that his service experiences, most of which were

in Korean combat, were any more traumatic than was to be expected.

When he was honorably discharged from military service in 1954, he entered the college where his younger brother had just graduated. He made average progress, earning B's and C's. He had only seventeen credits in student teaching to complete, and would have graduated in three months if his illness had not intervened. He said that while working at a summer factory job his headaches became more severe and recurred every day. He mentions losing "two-thirds" of his appetite. He says that as a result, he was "committed" to the local referring hospital, but it was difficult to ascertain what he meant by this. In June of the year before hospitalization, he was married to the girl he had gone with in college. His wife had just graduated from college at the time of their marriage, but could not teach because their child was born seven months later. He is excessively guilty and self-depreciatory about this and states, "It is illegal and irreligious to have premarital intercourse." He said that this baby was ill and had to have a craniotomy the following March. One wonders if he imagines that this development, plus his own illness, are forms of punishment for past misdeeds. This child is now ten months old and, just a few days ago, their second child was born. He says that his wife did not want to go through another pregnancy but "took it graciously." He seems to express genuinely warm and positive feelings toward his wife.

They have had to receive help from her parents, with whom he says he gets along well. They also receive help from the county welfare department, because of the baby's illness. This makes him feel quite ashamed, but worse than this, according to the patient, is the fact that he had to take help from his hated father during the past year.

The patient says that at one time in the past, he went to a psychiatrist who told him that he was just restless.

I would like Dr. Gilberstadt to complete the information we have on the mental function of this patient.

Psychologic Evaluation

Dr. Harold Gilberstadt (Chief of Clinical Psychology, VA Hospital): The patient was somewhat shy, passive and quiet in manner, but showed much interest in his performance on the tests and was curious about the results. His affect appeared to be moderately flattened, but not inappropriate. He responded quite volubly to questions, but lacked spontaneity and did not initiate topics. His most noticeable mannerism was a tendency to cough when sensitive areas were touched on. His speech was querelous.

On the Shipley-Hartford Intelligence Scale, the patient obtained a very superior Vocabulary score. On the Abstractions, he was just average. The best guess from this scanty intellectual testing is that the Vocabulary score represents some degree of overachievement (supported by the patient's assertion that the English language is his hobby) while the Abstractions score is an underestimate, due to his inefficiency. As a result, the estimated I.Q. of 115, in the high average range, is probably a good indication of his capacity.

In his written responses to the Biographical Data Sheet, the patient's schizoid tendencies were more clearly

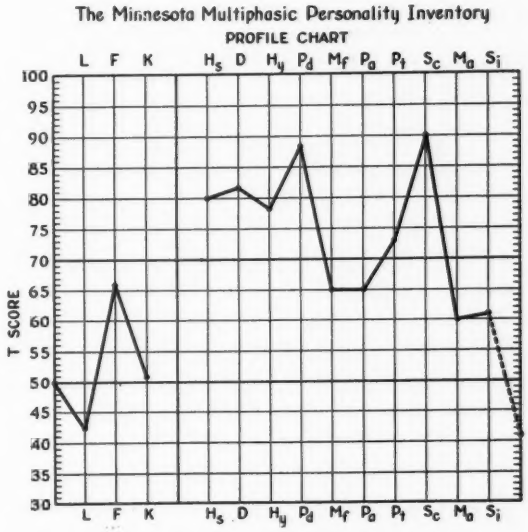

Fig. 3. The Minnesota Multiphasic Personality Inventory from a patient with ulcerative colitis. The dotted line leads to the ego strength scale, the value for which is below normal. Photography by Medical Illustrations Service, VA Hospital, Minneapolis, Minnesota.

apparent than in the face-to-face interview. His spelling was extremely poor for an individual about to graduate from a teacher's college. He mentions that he failed the third grade. His difficulties in educational achievement are probably of long standing. His peculiar stilted language is illustrated in his description of his mother's occupation as "pedagogue." In reply to a question about nervous trouble in the family, he responds, "My father is a mental aberration." When asked what his main interest is besides his work, he responds, "wife", and he says that his only hobby is "studying the English language." Marked inefficiency is evident in a tendency to drop letters from words and a failure to cross t's. In addition, he capitalizes words in a very idiosyncratic fashion. Although these are not unusual schizoid characteristics, the possibility of brain dysfunction from other functional causes should not be overlooked. The patient was reported to have been febrile at the time of testing.

The Bender-Gestalt does not show any marked impairment of ability to perceive reality, but his ability to plan and execute this simple task is inadequate, with the net result that his performance is not grossly deviant but is somewhat careless and below expectation in quality. His recall of only two figures is below average and suggests some type of memory difficulty. The over-all quality of his drawings is most suggestive of an individual who probably is experiencing some agitation and difficulty in concentrating.

The Figure Drawing is immature in general quality

and strongly shows schizoid confusion about sexual identification. He started his drawing with a woman's head and finished it with a boy's body. His comment about it was, "It started off as a woman, but I don't know if it's a woman or not."

The Rorschach shows intact ability to perceive reality and all of his responses are of good form. He does show a lack of productivity and is unable to give any responses to two of the cards. This is probably partly due to guardedness. He gives only single responses to the whole blots and is unable to selectively or systematically break down his responses into details. This is consistent with his lack of flexibility and efficiency in other intellectual performances. There is some evidence that he has an active fatasy life, but it does not appear to be bizarre. However, he does show a capacity to become overly involved, lose distance, and to become overly circumstantial on occasion. This is illustrated by his over-detailed response to the colorful Card X: "This reminds me of an artist's scratch cloth on which he gets rid of paint when he changes brushes while painting a many-colored picture. Before the change from one brush to the other, you wipe it on here blue, or red, or whatever, before you put it in the turpentine, or whatever you use to reduce out the paint you have to take off in the solution. This would account for the many shapes and colors smeared on the cloth before he put it back in the jar." This response suggests some inability to deal with the colored aspects of the card and/or the complexity of it, and shows his tendency to become idiosyncratic in the face of such difficulty. Considering the test as a whole, the fact that he was able to control his behavior and to be somewhat cautious is a favorable sign in a schizoid personality.

The Minnesota Multiphasic Personality Inventory (MMPI) profile is characteristic of an immature, highly dependent, self-depreciatory, guilt-ridden schizoid individual who does have some neurotic defenses such as somatization (Fig. 3).

DR. JOHNSEN: Thank you, Dr. Gilberstadt. If there are no questions at this time, I will ask Dr. Simon to review for us what is known about psychological factors in ulcerative colitis.

DR. WERNER SIMON (Chief of Psychiatry and Neurology, VA Hospital): Engel[2] has pooled the published reports of psychiatric data in more than 700 patients with ulcerative colitis. Detailed study of these patients reveals that major psychodynamic characteristics long antedate the appearance of the clinically-manifest disorder. The often repeated claim that the psychological findings are the result of the severe and debilitating disease finds no support when the patients are studied over a period of years, including long periods of complete remission.

Personality structure.—Many persons with ulcerative colitis are described as having obsessive-compulsive personality traits, consisting of neatness, orderliness, punctuality, conscientiousness, obstinacy or conformity. Frequently they are petulant, querulous, demanding, and provocative, but at the same time their feelings are easily hurt, their capacity to tolerate frustration is decreased, and their relationships with people are characterized by dependent attitudes. These traits are specifically associated with ulcerative colitis, although most people with such traits do not have the disease.

Relationships with people.—There is a rather consistent pattern—a dependent relationship on one or two persons and an incapacity to establish warm, genuine friendships with others. The dependency is with a parent or parent substitute, such as a physician. When these patients marry, the spouse often fulfills such a role. In this emotional symbiosis with the key figure, extreme sensitivity is displayed, and regardless of the degree of frustration, the patient finds it impossible to relinquish his own parasitic relationship. The choice of spouse is frequently determined along such lines, but also the choice of physician. It is well known that patients with ulcerative colitis either become very dependent upon their physician or establish a very superficial relationship with them. Those patients who develop such a dependent relationship, whether or not it is consciously planned by the physician, do better than patients who do not. Once a relationship has been established, it is unusual for the patient to relinquish it and remain in good health. He may leave the doctor because of negative feelings, but this is, as a rule, accompanied by a relapse, unless a substitute has been found. Any interruption of the doctor-patient contact, for example, the doctor being out of town for a few days or weeks, is likely to precipitate a relapse of symptoms. The patient may deny that the break in contact was of any importance to him, but with encouragement may be able to speak of his feelings about such separations and become more able to tolerate them. To leave a prescription or a telephone number, which the patient may never use, often serves as effective reassurance.

Mothers.—Generally the mother is described as controlling and dominating. She may make the patient feel helpless and dependent. She is often cold, strict, punitive and perfectionistic. She may sometimes assume the role of a martyr, sacrificing herself and suffering hardship, seemingly for the health and welfare of the patient.

Fathers.—Much less information is available about the fathers, who apparently play a lesser role and do not reveal any consistent pattern. Female patients often describe them as gentle, kind, and passive, while male patients refer to them as brutal, primitive, and threatening.

Sexual and marital adjustment.—In terms of overt behavior, interest and participation in sexual activity is low. Most of the women are frigid and rarely experience orgasm, while male patients have little heterosexual experience, even when married. Overt homosexuality, however, is not seen in these patients. Sometimes the wife fulfills the role of a sustaining mother,

although more often the wife takes a subordinate role to the mother and is treated more like a sibling.

Pre-morbid bowel history.—A majority of patients suffer from constipation, often dating back to childhood, prior to the development of the colitis. There is some evidence that bowel training may have been too early and punitive, and that frequent carthartics and enemas were administered by the parents.

Precipitating circumstances.—When we examine the circumstances under which the disease becomes manifest, it is often found that the time interval between a psychologically stressful situation and the onset of the first symptom of the colitis may be a matter of hours or a day or two. But there are also cases in which the onset is rather gradual and not easily correlated with a well defined stressful experience. The cases in the literature with acute onset seem to follow a pattern. Disturbing events preceding the mucosal reaction included a real or threatened interruption of a key relationship, demands for performance which the patient felt incapable of fulfilling, and an overwhelming threat from, or disapproval by, a parental figure. In cases beginning insidiously, with slight bleeding and mild diarrhea, gradually mounting pressures threatened the already precarious emotional adjustment. Some authors consider sudden loss of love, or painful humiliation, or delayed grief reaction as being precipitating life situations. These points of view are in essential agreement, but differ in emphasis.

Affect.—At the time of onset and during relapses, the feeling tone of the patient has been described as "helpless, hopeless, overwhelmed, or too much to cope with." Various authors use the terms helplessness, depression, humiliation or defeat in describing the affect.

Alternative symptoms.—Patients with ulcerative colitis may show alternative symptoms in the form of other psychosomatic disturbances. Among these are headaches, which either antedate the onset of the colitis, or occur during intervals between relapses. The occurrence of a headache during an attack of colitis often predicts the end of the attack. Observers, such as doctors and nurses, have frequently commented on the unusual aggressiveness or assertiveness of the patient during the time such headaches occur. Anorexia, nausea, and vomiting commonly accompany attacks of colitis, but some patients have the symptoms independently. The two major psychiatric complications which may be seen are psychotic depression and/or paranoid psychosis.

Fistula studies.—Grace, Wolf and Wolff[3] studied two patients with ulcerative colitis who had a colonic fistula, by simultaneous observation of changes in the bowel and the psychological state. It was concluded that life situations producing fear and dejection were associated with hypofunction of the large intestine, accompanied by pallor, lack of contractile activity and relatively low concentrations of lysozyme. Life situations provocative of conflict, with feelings of anger, resentment and hostility were associated with hyperfunction of the colon. These observations have been confirmed by other investigators.

Other psychodynamic formulations.—While psychoanalysis has yielded much valuable information about the psychodynamics of these patients, no systematic attempts to correlate the psychological and somatic processes have as yet been made, and much more careful evaluation is required before their validity can be established. Various investigators have emphasized different aspects. Alexander's formulation[4] is largely based on psychological aspects of the anal period of personality development. He postulates that colitis appears when the patient is facing a life situation which requires some outstanding accomplishment for which the patient feels unprepared and compares this with that phase of development in which the infant experiences the act of defecation as the giving up of a cherished possession on one hand and an accomplishment on the other. Szasz[5] suggests that colonic activation and inhibition, leading to diarrhea and constipation, represent the physiological sequelae of upper gastrointestinal tract activity, of which the gastrocolic reflex is the prototype. He does not believe that the bowel symptoms have any primary psychological meaning, but interprets them as manifestations of a vegetative neurosis. Sperling[6] has concentrated on the characteristics of the mother-child relationship and emphasizes the contradictory attitude of the mother who attempts to maintain her child in a life-long dependent state to satisfy her own needs, but at the same time shows unconscious rejection toward the child. Lindemann[7] has stressed the significance of the loss of a key person and the prominence of morbid grief, while Groen[8] points out a sudden loss of love which is felt as humiliation and the loss of a source of emotional support.

Why the colon is the primary site of involvement in patients with such problems has not been adequately explained.

DR. JOHNSEN: Thank you, Dr. Simon. Dr. Magraw, would you give us some of your ideas on the subject of ulcerative colitis, in general?

DR. MAGRAW: One of the lessons that ulcerative colitis has to teach us in the field of psychosomatic medicine is the recognition of the gap in our knowledge. We don't really know what causes ulcerative colitis. I think, personally, that it is a disorder in which the ultimate explanation will have to involve some recognition of the physiology of emotion. I, myself, suspect that the crucial emotion is grief, or the separation reaction. We have a problem of relating the emotion on the one hand, to the pathologic "endpoint" on the other. Many psychiatrists have, for years, turned their attention in this disorder to the symbolism of defecation, of riddance of noxious material. This is a characteristic approach, I might say. Psychiatrists, in general, in approaching psychosomatic difficulties, emphasize symbolism. The organically-minded physician tends to emphasize the more mechanistic aspects. Actually, I think both groups may have missed the point in their emphasis on the diarrhea. I am in complete agreement

with Engel when he points out that if we are going to understand this disease, we have to explain the whole story of it. Bleeding is the first symptom in the majority of cases. Diarrhea is by no means invariably present early in the disease. We don't have any pathognomonic way of identifying this disease. The differential diagnosis between this and other types of bloody diarrhea with friable mucosa still remains a problem. I personally think that the lesion which gives rise to the ulcerations develops in the intima of the terminal blood vessels of the wall of the colon. I suspect that we may find that there is something in the physiology of grief, or possibly anxiety, or maybe even rage that produces this effect.

Discussion

DR. JOHNSEN: Are there any questions?

DR. G. BEAUMONT (Fellow in Internal Medicine): How has the patient fared since his admission to this hospital?

DR. JOHNSEN: He has been afebrile for the last six days and is now having no more than two, non-bloody, well-formed stools a day.

DR. BEAUMONT: Do you think he has improved because of your support and reassurance or because of the rest and medications that he has received?

DR. JOHNSEN: Well, I think his improvement can be attributed to both factors. Certainly his colon is physically ill and has made his body ill. Rest and medications are important. He has been managed on a combination of sulfonamides, antispasmodics, vitamins, phenothiazines, barbiturates and constipating agents, together with a low residue diet. From the emotional point of view, he has temporarily escaped from the trap that he was in on his home grounds—that is, the threat of completing education and being expected to thereafter sever whatever immature bonds of family life he may have retained and go out into the world and function as an adult.

DR. W. GRIMM (Fellow in Internal Medicine): Are you implying that psychiatric care is necessary or even indicated for all such patients with this disorder?

DR. JOHNSEN: No, a psychiatrist is usually not necessary and may not be available. It should be noted, however, that there are a few cases on record in which it is felt that a permanent cure of ulcerative colitis has been obtained by means of long-term uncovering psychoanalysis. However, that is neither practical nor possible for most patients with this disorder. The community physician most often serves, sometimes unwittingly, as an adequate therapist for the emotional aspects of the disease.

DR. M. GOEPFERT (Staff Physician, Medical Services): I would like to ask Dr. Magraw if he has had any experience with shock therapy in patients with ulcerative colitis and involutional melancholia.

DR. MAGRAW: I can think of two such patients who did very well after electroconvulsive therapy.

DR. JOHNSEN: Are there other questions or comments? If not, I would like to ask Dr. Gilberstadt to sum up the case presented today, in the light of what we have just heard about ulcerative colitis.

Summary

DR. GILBERSTADT: The patient is a psychologically crippled, peculiar, rigid, immature, dependent, self-depreciatory and guilt-ridden individual, who is unable to cope successfully with the problems of his life. However, his problems have been difficult ones. From the time of his return from service he has been subjected to a series of stresses. These include his parents' divorce, his marriage after conception of their first child, the subsequent brain surgery on this child, the sale of the family home by the mother, the birth of the second child, the unhappy relationship with his father and, lastly, the imminence of finishing college and having to play a role in the world. He is attempting to imitate his mother and brother in his choice of teaching as an occupation. He himself has said that even the prospect of practice teaching was highly unnerving to him. Even more threatening was the eventual prospect of having to go out on his own to assume independence as a teacher. It was at this time that he developed colitis.

On the other hand, he has intact ability to perceive reality and appears to have a healthly fantasy life. He has considerable insight and, although not a good prospect for intensive psychotherapy or any basic personality change, the patient has sufficient strengths so that, with continued support from his wife and other sources, such as a physician, he should be able to make at least a marginally good adjustment.

GOUT

It has often been said that one need only think of gout to make the diagnosis. This statement is based on the solid clinical fact that in the great majority of cases the picture presented by the disease is characteristic. Because of this characteristic picture, gout is an ancient disease having been described very early in medical records.

As often happens, however, advances in medical science confuse as well as clarify and one of those areas of confusion has been described in a recent article.* The investigations presented led to the emphasis of two basic observations. Firstly, hyperuricemia is a trait widely distributed in the general population. When it occurs in association with joint disease differential diagnosis may be difficult since in the minds of most physicians hyperuricemia plus joint disease equals gout. The authors point out that such may not be the case and emphasize that the physician faced by this diagnostic problem will do well to recall the random occurrence of elevated serum uric acid values. He need feel no embarrassment over making the diagnoses of rheumatoid arthritis, degenerative joint disease, et cetera *and* hyperuricemia.

On the other hand, it was pointed out that in about one-fifth of gout cases the pattern of the disease is not the typical one described in the literature. It was the opinion of the authors that a detailed review of the diagnostic criteria for gout should be pursued in every case of obscure joint disease. In particular, the history should be studied for evidence of periodicity of symptoms especially in the early phases of the disease and for relationship of symptoms to operative procedures, trauma, strenuous exercise, the discontinuance of steroid therapy, or the administration of liver, mercury, or ergot. One should inquire regarding a family history of gout and search carefully for tophi in the subcutaneous tissues, in tendons, and in bone. Hyperuricemia is usual at some time during the course of gout, but one should not discard this diagnosis completely in the face of a normal value since often uricosuric medication, specifically Aspirin, will have been taken and in occasional patients this sign does not appear until late. The renal status should be studied. The history of the passage of a urate stone makes the diagnosis probable, and chronic renal disease is suggestive evidence. Finally, a prompt (twenty-four hours) response of joint symptoms to an adequate course of colchicine given early in an attack is an excellent sign favoring gout. Lack of response of chronic joint symptoms does not constitute evidence against gout.

The authors recognized the fact that in certain cases the diagnosis can only be established by continued observation of the patient, often over a period of years, however, they believe that, when gout is suspected, the differential points should be checked off in systematic fashion since, with the present availability of potent uricosuric agents, the course of the disease may be appreciably modified.

THE NEW MEDICAL SCHOOL IN SAINT PAUL

There has been ample documentation of the impending and significant shortage of doctors foreseen in this country in the next ten years. The Association of American Medical Colleges, the United States Department of Health, Education and Welfare, and the American Medical Association have all expressed their concern in this matter. The public has been alerted to this need repeatedly by numerous articles in magazines and other periodicals in the past year.

Something can and will be done about the situation. It is basically a public responsibility, and the public through its governmental agencies will rise to the occasion and endeavor to correct it. Is it not reasonable, then, that the medical profession as a whole provide the guidance and initiative in the answer to this problem before actual governmental action takes place?

As the need becomes more crucial, the federal government will no doubt create the needed

First of a series of three editorials on the proposed new medical school.

schools. We shall surely be paying for these schools through increased taxes and without significant control by the physicians who believe in the philosophy of free enterprise in medicine.

It is apparent that to provide more doctors, we must expand the medical teaching capacity both by enlarging the present schools of medicine and by creating new ones. Our present medical schools, including our own State University, are making heroic efforts to meet the need by increasing their student enrollment. But it is unreasonable to suppose that this enlargement of classes could go on much further without the possibility of jeopardizing the quality of training.

Another factor in this increase in capacity of medical education, which is worthy of some consideration, is the increasing numbers of the government (usually state) financed and controlled medical schools. In a country with the philosophy we have of preserving private enterprise, it appears that an equal or near to equal balance should be maintained between government institutions and private ones. There are few more powerful stimuli to the maintenance of quality than good competition.

The metropolitan area of Minneapolis and Saint Paul represents the only population center between Chicago and Seattle with enough clinical material to support another school. The states of North Dakota, South Dakota, and Montana have a present physician shortage which a private medical school nearby might ease a great deal. Both North Dakota and South Dakota have two-year medical schools. These states would welcome a private medical college nearer home for their third-year and fourth-year students to attend.

Minnesota is one of the leaders in higher education in the United States. Its literacy rate is one of the highest, if not the highest, in the country. The University of Minnesota, the Mayo Clinic and the numerous clinics in the state are evidences that in medical education this state is outstanding. What better setting could there be for the development of an outstanding private medical school?

Such a medical school, according to the latest rules of the Association of American Medical Colleges, would necessarily be connected with an existing college or university and give basic science as well as clinical training. In Saint Paul, there are several fine colleges giving an excellent environment for a new medical school. One of these colleges, in particular, is interested in having such a school in its academic structure.

At the present time, there is a more than ordinary possibility that the city of Saint Paul and Ramsey County will build a new city and county hospital. This, combined with the present Wilder Dispensary and the medical complex of several surrounding large private hospitals, would make an ideal home base for a private medical school. There are other large private medical complexes now under consideration in Minneapolis which could benefit immensely from academic association with such a school.

Such an undertaking, as everyone realizes, is a very costly one. For a medium-sized school having around seventy students in a class, the non-instructional cost would be about $350,000 a year and a minimum instructional cost of around $1,000,000 a year. This means an endowment of from $25,000,000 to $30,000,000 to provide this minimum of annual operating expense.

Preliminary studies show that there is more than enough private wealth in this area from which to raise such an endowment. It remains for those who have control of this potential endowment to be persuaded to underwrite this project. The need is a serious one, and this proposal of a new private medical school already appears to be an appealing one to most responsible citizens who have been appraised of the facts. Physicians have a duty to society to give their support to such enterprises as this.

N.A.M.E., Incorporated

ADRENOCORTICAL STEROIDS

There can be little doubt that the newer corticoids have increased antiinflammatory activity, but this increased potency becomes significant only when assessed against the incidence of known side effects. While the term "side effect" is used freely in association with corticosteroid therapy, it is understood that in most cases they are really physiological effects which because they are excessive become undesirable.

The side effects of corticoid therapy are well known and perhaps we should review them in order.

Edema or Fluid Retention—Cortisone and hydrocortisone are well known for their ability to lead to fluid retention and edema. While this is

valuable in the Addisonian patient, it represents a definite drawback to the therapy of other conditions. The predni-steroids eliminated this complication to a very considerable extent, and it is encouraging to note that the new corticoids also lack sodium-retaining propensity.

Gastric Intolerance—This was not a major problem of corticoid therapy until the introduction of prednisone and prednisolone but was frequently observed during continued administration of these very active compounds. Dyspepsia, indigestion, heartburn and epigastric distress have all been reported following the use of the predni-steroids. At present, there is evidence that these digestive disturbances are definitely reduced by the newer corticoids.

Peptic Ulcer—This has always been one of the major hazards of corticoid therapy not so much because of the frequency with which they occurred, but mainly because the symptoms of impending perforation or hemorrhage were completely masked and the patient was often in extremis before a diagnosis of this complication could be made. There is little doubt that ulcer formation occurs more commonly during prolonged therapy with a corticosteroid, and therefore, the newer corticoids have not yet been fully valuated in this respect. There is now some evidence to indicate that the concurrent administration of an anticholinergic agent during steroid therapy may be beneficial in cases where an ulcer is suspected. The virtue of upper G. I. tract x-ray examination during long term therapy with corticoids should also be given earnest consideration.

Mental Side Effects—Emotional disorders of a severe nature have been one of the more serious hazards of coricoid therapy. The euphoria noted may not be too objectionable in chronic illness, but with certain of the older compounds such as cortisone, mental changes were not limited to this relatively harmless effect. Depression, disorientation, frank psychosis and suicidal tendencies have been reported. The evidence at present is that the newer compounds offer a lowered incidence of these mental side effects, and to date no mental changes of a severe nature have been noted with either methylprednisolone or triamcinolone.

Moon Facies.—This is probably the most conspicuous of the Cushingoid symptoms seen during therapy with the earlier corticoids and it is also one of the most persistent side effects. As a rule it appears after prolonged low dosage therapy, but earlier in the high dosage therapy required for such conditions as systemic lupus erythematosus. Its incidence with methylprednisolone is low. There have been reports that with triamcinolone, in certain cases previously treated with other corticoids, this side effect may actually be reversed and the moon facies disappear.

Anorexia and Weight Loss.—These have been observed with one of the newer corticoids. In contradistinction, the older steroids often caused excessive appetite and weight gain which also was undesirable. There is at present no known explanation for this effect and further study is required. These unusual side effects have not been observed following the use of methylprednisolone.

Supraclavicular Fat Pads.—This side effect has been reported with methylprednisolone but to date has not been mentioned in the literature on triamcinolone.

Acne and Hypertrichosis.—These may both be regarded as essentially of a minor nature, but are somewhat unpleasant to the average patient. The newer corticoids appear to offer a relative freedom from these, although, one worker in the field did note an increased incidence of these minor side effects with triamcinolone.

Ecchymosis or Easy Bruising.—This side effect was comparatively rare with the older steroids but became much more prominent with the introduction of prednisone and prednisolone. There is some evidence at present that the newer corticoids may reduce the incidence of this side effect, but as yet a full evaluation must await the passage of time.

Diabetic Syndrome.—The diabetogenic activities of the corticosteroids are well known, and this phenomenon has been noted following the use of methylprednisolone. To date, no reports have appeared in this respect concerning triamcinolone.

Osteoporosis and Pathological Fractures.—It is impossible at this time for the incidence of these conditions to be fully evaluated with the newer corticoids, since they primarily result from long-term therapy.

Summary.—These four editorials have attempted to cover in some degree the pharmacology, the clinical potentialities, and the side effects of the newer corticoids. There can be little doubt that these compounds represent a major advance in therapy, and will make this form of treatment more acceptable to patient and physician alike.

JOHN J. PEPPER, M.D.

OXYGEN THERAPY AND ALLIED PHYSIOLOGICALLY BASED PROCEDURES IN PULMONARY EMPHYSEMA

The therapeutic use of oxygen generally results in more conspicuous clinical improvement in patients with pulmonary emphysema than in any other chronic illness. Relief of dyspnea, which is characteristic, is invariably paralleled by an elevation of the arterial blood oxygen saturation. The more severe the hypoxia, the smaller is the concentration of oxygen required to produce a significant increase in tissue oxygen tension, because of the steep slope of the O_2 dissociation curve between 60 and 80 per cent arterial oxygen saturation.

In addition to the symptomatic benefit produced by the consistent lowering of the burdensome ventilation, as well as the work of breathing, oxygen inhalation has often aided the restoration of cardiac compensation when routine measures were ineffective; in fact, it is among the chief effective agents for the management of both respiratory, as well as cardiac insufficiency.

However, so many warnings have appeared concerning "oxygen poisoning" and specifically against the use of oxygen in chronic pulmonary emphysema that patients have at times endured a dangerous degree of hypoxia which not only wrecks the machinery, as Haldane long ago said, but denies the therapeutic benefit that is so near at hand and so practical of administration. Abrupt administration of 40 to 100 per cent oxygen to cases of diffuse obstructive bullous pulmonary emphysema constitutes overdosage of oxygen which in this clinical entity is then followed by respiratory depression, and a clinical train of symptoms due to acid shift in pH and uncompensated respiratory acidosis. The hazards of this kind of oxygen therapy have too often been proclaimed without at the same time describing the proper method of administration. Intermittent positive pressure breathing (I.P.P.B.) treatments, even for ten minutes is often advocated with the inhalation of air, rather than 30 or 40 per cent oxygen. The advocates of intermittent pressure breathing devices for hyperventilation convey the impression that hyperventilation with these machines is apparently powerless against the lowering of the ventilation provided by an oxygen-enriched atmosphere.

It would seem that effective enhancement of the ventilation is not readily provided by the routine employment of most I.P.P.B. apparatus. Mechanically induced augmentation of breathing requires expert and almost continuous supervision. (From the viewpoint of therapeutic benefit, administration of caffeine is frequently overlooked as an effective respiratory stimulant. The patient with bullous emphysema in respiratory distress is not treated with oxygen concentrations over 30 per cent by mask, tent, or catheter, until three or four days previous acclimatization to lower oxygen percentages. One or two liters per minute by double bent tube is sufficient to increase the arterial pO_2 considerably in the presence of severe hypoxia, without respiratory depression, provided sedation is given under skillful management to avoid exaggerating the narcotic tendencies of acid shift in pH.

Concerning the possible toxic effects of oxygen, Lambertson has the following to say:

> "Clinically, the development of pulmonary oxygen toxicity is rarely encountered even when oxygen administration is continued over many days . . . no toxic manifestations have been observed with inspired oxygen concentrations below 60 per cent, and higher percentages are difficult to obtain with several commonly used techniques of oxygen therapy. A second factor detracting from the clinical importance of pulmonary irritation by oxygen is that its onset is delayed even by normal interruptions of therapy such as the routine care and feeding of the patient. Possibly for this reason, patients with cardiac decompensation, treated for several days with 100 per cent oxygen show no signs of pulmonary irritation.
>
> "It therefore appears that pulmonary oxygen toxicity is an unlikely complication of oxygen therapy in adults and is not a factor to be considered when deciding whether to begin treatment with oxygen."

The crucial advantages of a regimen of progressive increase in the oxygen concentration delivered to the patient has often been outlined and the physiological events initiated by oxygen therapy have been recently reviewed in detail. An evaluation of the mechanism of dyspnea in our clinic has indicated that the patient with emphysema does not respond to increased pCO_2 tensions when offered measures which increase gas diffusion in the lungs and decrease pulmonary effort.

The lowering of the pulmonary ventilation which is achieved by controlled oxygen administration results in a high pCO_2 in the arterial blood and alveolar air. The accompanying increase in CO_2 elimination per breath (or per liter of ventilation) permits the relief of dyspnea initially achieved by oxygen inhalation to continue without acid shift in pH; in addition, the compensatory stimulus to the outpouring of chlorides constitutes a significant advantage in patients with cardiac insufficiency, facilitating the characteristic diuresis. Of special interest in the fact that the work of breathing, as measured by the oxygen consumption, is strikingly diminished as dyspnea is relieved, and, consequently, the production of CO_2 is lessened correspondingly. Furthermore, during walking exercises, administration of oxygen in concentrations of 28 to 50 per cent can be inhaled *without previous acclimatization,* with the development of cardiorespiratory reserve as a direct consequence of physical exertion. *No undue depression of respiration* has been observed during the past ten years in severe cases of bullous emphysema when the patient is walking. Ultimately, the capacity to walk breathing air is achieved by preventing the development of severe hypoxia and an unduly increased ventilation.

Instead of the so-called vicious cycle of CO_2 retention due to inhalation of oxygen, the response is indeed benignly opposite! The cycle is advantageous provided controlled oxygen therapy is utilized. The attempt to lower by mechanical means the elevated CO_2 levels in the compensated emphysematous patient (i.e., the patient with normal pH and CO_2) is generally futile, since the effect on the blood carbon dioxide is slight and transient. If indeed the pCO_2 and bicarbonate were significantly depressed by deliberate hyperventilation, increased respiratory efforts by the patient to eliminate CO_2, at a lower alveolar CO_2 would follow, since no improvement in diffusion would be accomplished. With an increased ventilation, an increased CO_2 production would ensue; more energy is required for breathing than a comparably elevated ventilation would produce in normal subjects.

The priority of the factors which lower the effort (and work) of breathing over the respiratory center's response to CO_2 has been observed in a variety of therapeutic measures applied to patients with diffuse obstructive pulmonary emphysema:

1. Diaphragmatic breathing, instituted instead of upper costal respiration, and accomplished by
   (a) The head-down position.
   (b) A 20 to 30 pound buck-shot bag on abdomen.
   (c) An emphysema belt.
2. Inhalation of bronchodilator and bronchovasoconstrictor aerosols.
3. Increase in reserve volume tidal air.

These procedures which increase the efficiency of breathing are generally characteristically followed by a lowered minute volume of respiration; the corresponding relief of dyspnea is not accomplished at the expense of physiological impairment. In several investigations in which the effects of the above described procedures had been studied, the pCO_2 is not altered. The patient, unless afflicted by psychoneurosis, does not choose to hyperventilate if offered an opportunity to decrease respiratory effort, provided this opportunity is based on therapeutic procedures which enhance alveolar diffusion of O_2 and CO_2. Another illustration of the value of oxygen therapy will be presented.

Enchancement of the general activities, physical and mental, of the patient with pulmonary emphysema, the aim of rehabilitation therapy, is now provided in more practical ways by various recently employed apparatus to administer oxygen. A lightweight cylinder containing 180 liters of oxygen makes it possible for the patient to walk thirty to forty minutes, at an oxygen flow of 6 to 4 liters per minute with approximately 3 pounds over his shoulder; in addition, a pocket oxygen device (called Oxy-Hale) has been equipped with a venturi by which oxygen administration may be carried out for two minutes, or, with three connected cylinders, for three to six minutes, depending on the concentration selected.* A metal sleeve, which fits over the venturi, may be adjusted to provide 28, 32, 40, or 50 per cent oxygen. The acute dyspnea which so many of these patients suffer on exertion may be treated in this way, and, thereby, free the patient for excursions to friends and places of entertainment which otherwise an apprehension of dyspnea might forbid.

Oxygen treatment has had its ups and downs! It is regrettable that in recent years so much has been done to frighten the practitioner against the proper employment of a remedy of such crucial value to the patient with pulmonary emphysema. Priestly said of his discovery: "Who can tell but

*Controlled Pressure, Inc., Box 1933, Erie, Pennsylvania.

that in time this gas will become a fashionable article in luxury. Hitherto, only two mice and myself have had the privilege of breathing it." The fashion of oxygen therapy appears to be on its way again.

ALVAN L. BARACH, M.D.

SINGLE CHARITY FUND DRIVE

A single annual charity fund in a community is favored by many physicians. The continuous procession of appeals for funds by friends, patients and thru the mail would cease at least for a while. Only one soul searching expedition would be necessary. Many fewer man hours would be expended collecting funds. The joint United Fund or United Community Fund organization could take over our charity problems. Everyone would be happier —or would they?

Physicians are keenly interested in the "Third Party" and its complications. They certainly know that in certain situations the "Third Party" does not represent medicine at its best. Voluntary health agencies are as individualistic as people. They have been struggling for their very existence with a "Third Party," the United Fund. The American Cancer Society, American Heart Association and many other excellent organizations could be rendered impotent and sterile by a loss of a personal control of their personal drive for funds.

In its usual thorough and democratic procedure, the House of Delegates of the American Medical Association at the last San Francisco meeting resolved:

"That the House of Delegates reiterates its commendation and approval of the principal Voluntary Health Agencies." "That it is the firm belief of the American Medical Association that these agencies should be free to conduct their own campaigns of fund raising and public education and to direct programs of research in their particular spheres of interest."

Even if municipal laws enforcing single or United Fund drives were constitutional, which they are not (see Supreme Court ruling on Dayton, Ohio vs. American Cancer Society Inc.), one should carefully examine the effect of such laws on the voluntary health agencies. These are important institutions in our way of life.

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

UNLICENSED CHIROPRACTOR SENTENCED AT CHASKA FOR UNLAWFUL SALE OF DRUGS

On November 17, 1958, Ernest Bartels, thirty-two years of age, Hamburg, Minnesota, was sentenced at Chaska, Minnesota, by the Hon. Harold E. Flynn, Judge of the District Court, to pay a fine of $100.00 or serve thirty days in the Carver County jail for selling drugs while not being licensed as a pharmacist. Judge Flynn then suspended the sentence and placed the defendant on probation to the Court for one year. The defendant had been charged previously in a complaint signed by a representative of the Minnesota State Board of Medical Examiners with maintaining an office for the practice of healing without having a certificate of registration in the basic sciences. However, due to special circumstances which arose after the issuance of the complaint, a motion was made to the Court by the Carver County attorney to reduce the charge to that of unlawfully selling drugs. Judge Flynn granted the motion and then immediately sentenced the defendant as stated above.

When Bartels was questioned by Judge Flynn prior to being sentenced, he stated that he graduated from high school in Belle Plaine, Minnesota, in 1944, after which he served in the armed forces. Upon his discharge from the army, Bartels said, he attended a railroad telegraph school in Minneapolis and then went to San Antonio, Texas, where he attended the Texas Chiropractic College for four years until 1953. According to the defendant, he began the practice of chiropractic in St. Joseph, Missouri, in 1954 but practiced for only four months. Bartels had been arrested after an investigation disclosed that he had sold three bottles of "Abundavita" tablets to a Cologne, Minnesota, man for $24.00. The defendant admitted to the Court that he had sold the tablets but called them a "food supplement." Bartels has no license to practice any form of healing in the State of Minnesota.

TWO FELLOWSHIPS OFFERED IN AUDIOLOGY AND SPEECH

Opening of competition March 6 for two fellowships in audiology and speech at Northwestern University has been announced by the American Hearing Society, its member agency, the Saint Paul Hearing Society, and the University. Winners of the awards, known as the Reine Humbird Myers Fellowships, will receive $3,000 a year for two years while participating in a graduate program in preparation for work in local hearing societies.

The fellowships were established in 1957 through a bequest from the Myers Foundation of Saint Paul, Minnesota.

Further information and applications may be obtained from Crayton Walker, executive director, American Hearing Society, 919 18th St., N.W., Washington 6, D. C. Closing date for returning completed applications to Mr. Walker is April 6.

President's Letter

THE DOCTOR'S BILL

In this age of rising costs of practically everything, the medical profession, of course, seems to be a favorite target for magazines, newspapers, and politicians to take a shot at. They all seem to forget, however, that our overhead has increased a great deal also in such items as increased rent, higher wages, cost of equipment, and supplies.

In a recent letter from Governor Orville Freeman, he says that the state has experienced an increased expenditure for medical services of 1.5 to 2 million dollars per year during the last period.

However, the Governor did not give the breakdown in the items that are included in this so-called tremendous figure. Actually, during the past several years in Minnesota, medical fees account for only about 10 per cent. whereas hospitals, nursing homes and domiciliary care account for more than 75 per cent and drugs about 9 per cent.

Even with our practice in general, more physician-patient relationships have been strained by a misunderstanding about fees than perhaps any other disagreement. The first safeguard against this misunderstanding is an explanation of fees being charged.

Some doctors believe they lack time for a frank discussion of these matters with patients, but lack of time is not a valid excuse. A patient has every right to know why he needs treatment or surgery, what it will consist of, and what it will cost—particularly where major services are to be rendered.

For minor services, a charge slip often can give the necessary information to the patient. But even if a charge slip is used, the end of the month statement should be itemized. Too often patients forget how much service was rendered during the month. Thus a brief statement reading, "For professional services—$75," may seem to the patient to be "too high." An itemized breakdown usually will avoid this common misunderstanding.

It should also be known that generally the patient's reaction to a fee is determined more by the doctor-patient relationship than by the size of the fee itself, or by the quality of medical care given.

Dr. Harry Ungerleider, director of medical research for the Equitable Life Assurance Society, recently stated that medical fees account for only about 10 per cent of all illness costs. Drugs take 11 per cent and hospital costs most of the rest. The doctor usually orders these other things, so people often tend to blame him for all the high costs of care.

We must look to our laurels and improve our physician-patient relationships. This poses a special challenge of self-discipline to the medical profession. Also, doctors may find themselves under occasional pressure from a patient to collaborate in abuse of insurance protection. The best answer to this problem is probably a continuing awareness by the medical profession of the importance of professional integrity.

HEALTH FIELD LURES LABOR UNIONS

The following article by W. F. Francka, M.D., president of the Missouri State Medical Association, has been reproduced in a number of the state medical journals throughout the United States. Because of its significant general implications, the article is also reproduced in this publication for your attention and consideration.

The third-party element continues to grow in influence in the practice of medicine as labor expands its welfare programs in the health institute field.

One of the latest to enter the field is the St. Louis meatcutters' union with a "one-stop" medical center as it was described by reporter Ted Schafers of the *St. Louis Globe-Democrat.* The new structure in St. Louis, built at a cost of one million dollars, is expected to have an annual operating budget of $300,000.

Funds to provide care for some 2,200 meatcutters and their families come through fringe benefits negotiated by the union. As Schafers said:

> "Such protection does not come cheap. It only seems so to the workers because employers in most instances are paying bills through union-negotiated health and welfare contracts."

Benefits Go Both Ways.—Preventive medicine and how it will cut down on absenteeism is stressed by the union as one of the benefits of the new clinic. Actually, the program also gives the union an even stronger hold over the union member because it takes over another area of his personal life, his health.

"We are going to make it part of our contract that every meatcutter must take a complete physical checkup at least once a year," the union president said. "We are going to concentrate first on the medical phrases; the dental work will come later."

It, of course, is impossible to argue with the wisdom of a physical examination each year. But for a union official to talk of imposing it on his constituents is another thing.

Automatically, the free choice of whether a butcher wants an annual physical examination or not is destroyed, not to mention quite a bit of the element of free choice of physician, if the butcher wishes to go outside the panel of physicians offered to him by the clinic.

And why would the meatcutter be told to get a physical examination each year?

Deeper Than Mere Health.—Ostensibly, because it is good for his health. But looking at it from another side, this just helps round out the power of the union president. It gives the union yet another control over its constitutents.

It also gives the union more bargaining power with the employers who are forced to pick up the check for the health clinic. To the meatcutter's boss and the consuming public, the union chieftain can point out how the public is protected by having healthier meatcutters.

But what of the individual butcher? He has just signed away another freedom in return for what he feels is economic betterment. By the time he adds up his dependence on the union, he virtually is living in a segregated socialistic society run by the union leaders. Once a complete retirement plan is worked out for him, he will have few decisions to make.

The growth of labor health centers is part of a pattern across the nation. The field of fringe benefits offers a wealth of rich-sounding phrases and services that help weld union cohesion. Health and welfare benefits normally are administered by the union officials, and if a worker does not choose to avail himself of them, it is only the worker's loss.

Hard Not To Go Along.—However, the worker usually sees that health benefits actually are part of his salary and he can ill afford to continue going to his old family doctor. It has a special appeal to the worker with a large family. Mother can take all the kids down to the union clinic for a checkup without paying out a dime. This doubly appeals to her if the doctor there treats her nice and appears to be competent.

The success and future of the labor health institutes depend upon these factors. If they satisfy

the workers and their families, they doubtless will continue to grow.

Two other labor groups in the St. Louis area already have indicated a keen interest in such programs, according to the *Globe-Democrat*. They are the carpenters' organization with 10,000 members and the machinists with 15,000.

To give some indication of the scope of the health and welfare field, it has been estimated by the Department of Labor that about 8 billion dollars is invested annually in such programs.

UMWA a Third-party Giant.—One of the early leaders in the field was the United Mine Workers Union. In the fiscal year ending June 30, the UMWA is reported to have spent more than 58 million dollars for hospital and medical care.

There was a major controversy in the last AMA House of Delegates over the relations between medicine and the UMWA Welfare and Retirement Fund. As it came out, the House called for an immediate public relations campaign to educate the public to the restrictions to free choice of physician and hospital being imposed by the UMWA.

Yet another giant in the labor field is even now examining the health field. The United Steelworkers Union has called for a broad study with the view to setting up union-operated hospitals and clinics in areas which it feels may need them.

"We are confident that a united and determined membership can win the goal of full medical security for all steelworkers through the process of collective bargaining," union spokesmen declared.

This trend toward more and more union-negotiated health and welfare institutes is surprising in view of the increasing availability of voluntary and commercial insurance plans which allow free choice of physician and facilities. It is difficult to understand why the unions do not use these funds to purchase voluntary health insurance plans. Through such a method free choice of physician automatically is available to the workers. This would eliminate at least one of the objections of the medical profession to such programs. In view of recent congressional investigations into the management of union welfare funds, insurance programs would seem to provide the stable protection that the workers have a right to expect at a price commensurate with the benefits of the insurance policy.

CENSUS BUREAU REPORTS HIGH BIRTH RATE—INCREASED DEATHS

Births in the United States continued at a high level for the fiscal year ending June 30, but there was a slight slowing down of population growth, apparently because of the increase in the number of deaths, according to the Bureau of Census population estimates.

Births for the fiscal year 1958 totaled 4,300,000, or 24.8 births per 1,000 of the population. However, the Bureau predicted, births in the second half of 1958 will be "appreciably lower" because of the recent decline in marriage rates.

The slight slowing down of population growth in the year ending June 30 was apparently due more to the increase in the number of deaths during 1957-58 than to any change in the number of births.

For the 12-month period ending July 1, 1958, deaths in the United States numbered 1,679,000 as against 1,579,000 deaths in the previous year. The death rate reached its highest level in recent years in 1957-58, with 9.7 deaths per 1,000 population. The Bureau noted that most of the excess of deaths in 1958 over 1957 was concentrated in the late fall and early winter of 1957-58, when the influenza epidemic occurred.

CONGRESS HAS FOUR PHYSICIAN MEMBERS

Minnesota's Doctor Walter Judd is one of the four physician members of the 86th Congress. This is one less than the 85th Congress. Returned in addition to Doctor Judd were Doctors Thomas Morgan and Ivor Fenton, both of Pennsylvania. The new addition is Doctor Thomas Dale Alford, a board ophthalmologist of Little Rock, Arkansas, where he has been in active practice since 1948. Doctor Alford, 42, was educated in Arkansas schools and received his medical degree from the University of Arkansas. He served in the Army Medical Corps during World War II.

Doctor Morgan, who has been acting chairman of the House Foreign Affairs Committee since last summer, is slated to become chairman when the new Congress is formally organized. He will thus be the first physician chairman in the 136 years of the committee.

Defeated in recent elections were Doctors Will Neal of Virginia, and A. L. Miller of Nebraska.

WHO NEEDS A FORAND BILL?

In 1951, among a total Blue Shield enrollment of twenty-one million persons, nearly a million, or a little less than five per cent, were over sixty-five years of age. Six years later, in 1957, among the total of *forty million* persons enrolled, two and one-half million, or six and one-half per cent, were over age sixty-five. Thus, in these six years, the number of Blue Shield members over sixty-five increased 170%, while total Blue Shield enrollment increased only about eighty-five per cent.

Attention was called also to the fact that of the total number of people past sixty-five who have medical-surgical insurance coverage, about two-thirds are covered by Blue Shield.

Of all the people in the U.S., it is estimated currently that about fifteen million are over sixty-five years old, and are not cared for by an established institution or agency. This represents approximately eight per cent of the total population. Thus Blue Shield's ratio of 6.5 per cent over age sixty-five is reasonably related even now to the ratio of the total population in that group—and rapidly approaching parity with it.

Until recently, it was almost an exclusively Blue Shield feature that any member on retirement, or on leaving an insured group, could retain his coverage by "conversion" to a "direct-pay" basis.

THESE FIGURES SPEAK FOR THEMSELVES

According to the *Journal of Rehabilitation,* there are now 1,236,000 physicians serving the world's 2,700,000,000 inhabitants and the 638 medical schools operating in eighty-five countries graduate annually about 67,000 new doctors.

There are fourteen countries fortunate enough to have one doctor to serve every thousand or fewer people. But there are twenty-two others where there is only one doctor for 20,000 or more inhabitants.

While nine countries have one medical school for less than one million of population, there are thirteen countries with only one such school for nine to seventeen million people.

Of the 51,534 persons in the employ of the Department of Health, Education and Welfare, 2,376 (4.6 per cent) are in the "disabled" category.

Of the 70,940 persons rehabilitated through the state-federal program of vocational rehabilitation in fiscal 1957, approximately 53,000 were unemployed when they began to receive services. Some 14,000 had been on the relief rolls, receiving $11.4 million annually. The total, one-time cost of rehabilitating them was $11.1 million.

PHYSICIANS ARE TARGETS FOR INCOME TAX CHECKS

It is becoming increasingly apparent that the Bureau of Internal Revenue has launched a concerted campaign in an attempt to uncover suspected income-tax evaders among the ranks of the medical profession. Individual tax returns have been crossed-checked in many instances for possible discrepancies. Accuracy of employe social security and withholding tax entries have not been overlooked by representatives of the Bureau of Internal Revenue.

A careful review of daily and weekly patient fee entries recorded has been frequently noted. Scrutiny in expense claims has been the rule. Not uncommon is the fine tooth comb treatment of all the offices in an entire medical building. The doctor's secretary is not immune to a tax third-degree.

According to law, physicians in partnership must file income data with the Bureau of Internal Revenue in addition to individual returns of members of the partnership.

Penalties have been assessed in a number of instances against physicians who do not maintain depository receipts for quarterly payments of taxes.

Tax men have exercised their perogative to police the narcotic handling and recording practices.

Don't forget April 15, 1959, is the deadline for state and federal income tax returns to be filed. An ounce of precaution now may help avoid pounds of inconvenience at a later date.

PHYSICIAN'S ENTERTAINMENT EXPENSE DEDUCTIONS DEFINED

The physician's entertainment expense deductions were recently defined in a tax ruling by the Department of Internal Revenue. The ruling states:

"1. A physician may deduct on his Federal income tax return the costs of entertainment, provided he can establish to the satisfaction of the Internal Revenue Service, by appropriate evidence, that such expenses are ordinary and necessary business expenses and clearly related to the production of business income.

"2. The amount of the deduction must be proven and its reasonableness determined. Once the amount

is established, the deduction may be claimed when the doctor is able to show that the entertainment had a direct relationship to the conduct of his practice, and can show the business benefit reasonably to be expected from the expenditure. The general statement that he hoped or expected to get referrals or patients as a result of the entertainment is not enough. If personal reasons predominate, the expenditure may not be deducted, even though there is some possibility of a business benefit. Except in the case of industrial physicians, entertainment of individuals who are not doctors will not ordinarily qualify because the possibility of benefits to be expected are so remote as to be neligible. In some instances of the entertainment of patients, the same general rules apply as in the entertainment of other doctors, and the clear relationship of the expenditure to reasonably expected income must be shown. The same rules also apply to civic and other club dues.

"Criteria to be used in establishing the deductibility of entertainment expenses include, but are not limited to, the following:

(a) Specific purpose of entertainment.

(b) Nature of the practice of the doctor incurring the expenditure.

(c) Period of time the doctor has been in practice and the number of patients he already has.

(d) Percentage of his patients received as referrals.

(e) Names of individuals entertained and reason why additional income could be expected from each.

(f) Whether or not referrals were actually received from the doctors entertained and any indication of the effect of the entertainment on these referrals.

(g) Number of times individual doctors were entertained during the year, inasmuch as repeated entertainment indicates a personal motive.

(h) Whether or not other doctors in the same type practice in the locality have entertainment expenses."

Further information on the preceding cases may be obtained from the Law Department. American Medical Association, 535 North Dearborn Street, Chicago 10, Illinois.

MARRIED WOMEN PHYSICIANS STAY WITH MEDICINE

The results of a recent survey made by The Association of Medical Colleges refute the common belief that it is a waste of highly specialized education for women to study medicine when most of them abandon the profession to become housewives. The survey reveals that most women physicians practice medicine after finishing school, though some declare a brief hiatus in their careers to have children. Almost 30 per cent of the women physicians decided against marriage while approximately 3 per cent of their men colleagues are bachelors. Most popular specialties for the women M.D.'s are pediatrics, psychiatry and neurology, and obstetrics and gynecology. Few women become surgeons. An estimated 5 per cent of the nation's 7,500 medical students are women.

Minnesota Blue Shield—Blue Cross

More than $50,000,000 has been paid by Minnesota Blue Shield for doctors' services rendered participant subscribers since the Plan began operations in November, 1947. This milestone was attained during December, 1958, and as of December 31, 1958, Blue Shield allowances for physicians' services during slightly more than eleven years of operation totaled $50,262,000.

The tremendous progress made by Minnesota Blue Shield in eleven years of operation is shown by the fact that during 1958 alone, nearly $10,000,000 was paid for physicians' services rendered subscribers, actually $9,686,819. This figure greatly exceeds Blue Shield allowances in any previous year and it surpasses the 1957 total by more than $1,200,000, or nearly 15 per cent. During the twelve months of 1958, Blue Shield payments for doctors' services rendered participant subscribers averaged over $807,000 each month.

Similarly, the number of doctors' services for which Blue Shield made payments in 1958 far exceeded the number of services for which allowances were made by Blue Shield in any previous year. During 1958, Blue Shield made allowances for 365,654 doctors' services, 58,483 or 19 per cent more services than were provided Blue Shield allowances during 1957.

Blue Shield participant subscribers numbered 889,943 as of December 31, 1958, approximately 20,000 more than the number of participant subscribers as of the same date in 1957. Percentage-wise, the increase in the number of participant subscribers is much less than the increases in payments and doctors' services which are apparently attributable to greater utilization of the contract by participant subscribers and the continued expansion of the contract in providing allowances for more of the services rendered by doctors of medicine.

Minnesota Blue Cross completed its twenty-fifth year of service during 1958. Since March, 1933, Minnesota Blue Cross has provided 15,187,515 days of hospital care benefits to 2,498,074 participant subscribers. Nearly 210,000,000 has been expended by Blue Cross for these hospital services provided.

The year 1958 shattered all previous records of hospital utilization incurred by Blue Cross subscribers. The 215,729 hospital cases paid represented more than one case incurred by every two contracts in effect. The 1,332,580 days of hospital care provided was an increase of 99,088 days over the previous high recorded during 1957 and represented over three days of hospital care provided for each contract in effect. Hospitalization expense during the year totaled $33,894,967, an increase of $5,262,562 over 1957 experience.

The phenomenal increase in Blue Cross utilization continues to be attributable to the rising trend of hospital costs and increased subscriber usage of Blue Cross benefits. Nearly seventy per cent of the increased subscriber usage is attributable to the increased numbers of subscribers hospitalized for medical care. Within the medical care area, two-thirds of the increase is due to subscribers incurring hospital medical care due to diseases of the digestive system.

Blue Cross membership as of December 31, 1958 totaled 1,143,467 participant subscribers, an increase of 5,500 over the number of participant subscribers protected as of the same date a year ago.

"DEAR DOCTOR" LETTERS EXPRESS DESIRE FOR MORE HEALTH INFORMATION

We get letters—lots and lots of letters. The mail response to the Minnesota State Medical Association programs, "Doctor's House Call," and "Your Health" on WCCO radio, as well as the "Doctor, Tell Me" series are at an all time high.

Unlike Perry Como's letters, which we assume relate to the lighter side of life, each of these letters is written testimony to some individual in need of a clearer explanation from the individual's personal physician regarding a particular health problem.

This is all the more reason why it is important for the physician to present answers to his patient's health questions in lay terms—easily understood by the patient.

PHYSICIANS HOLD PROFESSIONAL LEADERSHIP IMPROVEMENT FORUM

Several hundred Buffalo, New York, area physicians recently became "patients" as eight experts diagnosed their social, economic and civic "health" in a unique meeting.

The occasion was a forum on "The Doctor and His Practice" co-sponsored by the Erie (New York) County Medical Society and The Wm. S. Merrell Company, Division of Vick Chemical Company, at the Statler-Hilton Hotel. It was the second in a series of national medical economics meetings presented as a service to physicians by Merrell, century-old Cincinnati, Ohio, ethical pharmaceutical manufacturer.

Doctors attending the meeting were counseled on improving their dealings with patients, staff and community; their office and business management procedures; protecting themselves against professional liability suits; selecting their investments, insurance and planning their estates.

The physicians were advised by the experts that doctors can no longer rely solely on cultivating clinical skills. They must take the responsibility for improving their relationships and developing medical services that answer the changing needs of American society.

They were also warned that their professional future dictates that doctors find the time now to educate themselves on their individual and social responsibilities, lest they abdicate medical leadership entirely tomorrow.

Those conducting the forum also predicted that American physicians have the wisdom and resources to meet the challenge of these new social and economic problems in medicine.

ORIENTATION WORKSHOP

An orientation workshop for new component medical society presidents and secretaries, was recently sponsored by the Medical Association of Georgia. Purpose of the workshop conference was to afford newly elected county society officers an opportunity to learn about the function of society operations.

"Structure of County Society Organization," "County Society Management," "County Society Public Service," "Outstanding Examples of County Society Activity," and how "Medical Association of Georgia Can Help Your Society," were topics discussed at the one-day session. All officers of the seventy-county society association of Georgia received invitations to attend. Mr. Leo A. Brown, Director of the Communications Division, American Medical Association, was among the program speakers.

HUMAN RELATIONSHIPS According to Woodrow Wirsig, editor of Printers' Ink, New York, a survey of editors discloses the feeling that "medicine today is dangerously impersonal." Many editors, Mr. Wirsig said, "receive a floor of 'help-me' letters" from people who are desperately in need of a "personal relationship with a doctor they can trust as a friend and counselor."

As a yardstick for professional action, Mr. Wirsig urged that doctors undertake a continuing study of the public's attitude toward medicine and "what people want from doctors."

Treatment of the patient "begins in the waiting room," John R. Sedgwick, Chicago medical office management consultant, told the physicians' meeting. "The patient expects consideration for his comfort as well as his ills. Nobody likes to be kept waiting too long, including the patient," Mr. Sedgwick pointed out. This consideration might even logically begin outside the office, with adequate provision of parking facilities for the patient, he added.

A SLIP OF THE TONGUE COULD BE COSTLY "Be as careful with your tongue as you are with your scalpel", Erie (New York) County Medical Society members were advised at the same forum on "The Doctor and His Practice." The advice was presented by Mr. R. Crawford Morris, veteran attorney.

Other recommendations given by Mr. Morris to avoid possible liability suits were:

1. Never guarantee a cure unless you mean to be held to it.
2. Watch the time factor. In most states the patient has one year within which to sue you for malpractice, whereas you have six years within which to sue her for your bill. (In Minnesota, it is two years from the date of last treatment.)
3. Keep up with the advance of medicine.
4. Do not experiment unless you have the patient's permission in writing.
5. Get the patient's consent for everything you do, preferably in writing.
6. Good housekeeping. Keep good records, full and adequate.
7. Do not be negligent. If you feel the case is beyond your experience, do not hesitate to call for a consultation and make a writteen record of the consultant's opinion.

FOOD FOR FUTURE THOUGHT A one-day Public Relations Institute was recently conducted by the Medical Society of New Jersey. The event was sponsored by the Medical Society of New Jersey in conjunction with the Subcommittee on Public Relations. Its purpose was to review all the pressing problems of public relations concerning the state society and its component societies, and through formal presentation and from discussions, to agree upon steps to deal with the situation.

Invitations were sent to all officers and board members of the Medical Society of New Jersey; to the members of the Subcommittees on Public Relations and Medical Practice; to the presidents, secretaries, and executive secretaries of component societies; to all chairmen of public relations committees of component societies, and to representatives of the Women's Auxiliary.

"Analyzing our problems," was the title of the opening morning session devoted to a panel of speakers who discussed critical phases of medical public relations.

The afternoon session was dedicated to "Finding Solutions" for problems discussed in the morning session.

The opening topic discussed at the morning session was "Medical Public Relations—Philosophically and Practically Considered." Other topics discussed included: Medical Public Relations and the Individual Physician; Organized Medicine; Economics; Legislation; and the Common Good.

IN DEBILITATING DISEASE

Patients receiving

NILEVAR®

Eat more...
Feel better...
Recover faster

Compared to control patients, those receiving Nilevar (brand of norethandrolone) have repeatedly demonstrated more rapid and more complete recovery from serious acute illness and increased comfort and well-being in chronic illness.

A multitude of case histories are now adding individual clinical color to the earlier controlled investigations which defined the actions of Nilevar as an effective aid in reversing negative nitrogen balance and in building protein tissue.

In typical case reports such gratifying comments as these appear:

Underweight —"Appetite considerably increased within one week. Sense of well-being and vigor increased along with increased appetite."

Prematurity (Birth weight: 2 pounds, 4 ounces) — "Gradual improvement in appetite and capacity for formula. . . . Excellent progress and weight gain for a very immature infant."

Carcinoma of the Uterus —"Within four days appetite became excellent, took full diet. . . . More ambition while on Nilevar. Enjoys life. Takes part in church and other social affairs."

Third Degree Burn—". . . soon began eating all that was offered. . . . Began to show signs of hope for recovery. . . . Perhaps one of the greatest changes was in the appearance of his wounds which were so very much improved."

The dosage for adults is 20 to 30 mg. daily in single courses no longer than three months. For children the daily dosage is 0.5 mg. per kilogram of body weight, in single courses no longer than three months.

Nilevar is supplied in tablets of 10 mg., ampuls of 25 mg. (1 cc.) and Nilevar Drops of 0.25 mg. per drop.

NEW YORK UNIVERSITY POSTGRADUATE MEDICAL SCHOOL

Surgery of The Hand—a full-time course, March 16 through 21.

Orthopedic Aspects of The Treatment of Rheumatic Disorders—a part-time course on three successive Tuesdays, 9 a.m. to 5 p.m., March 17-31.

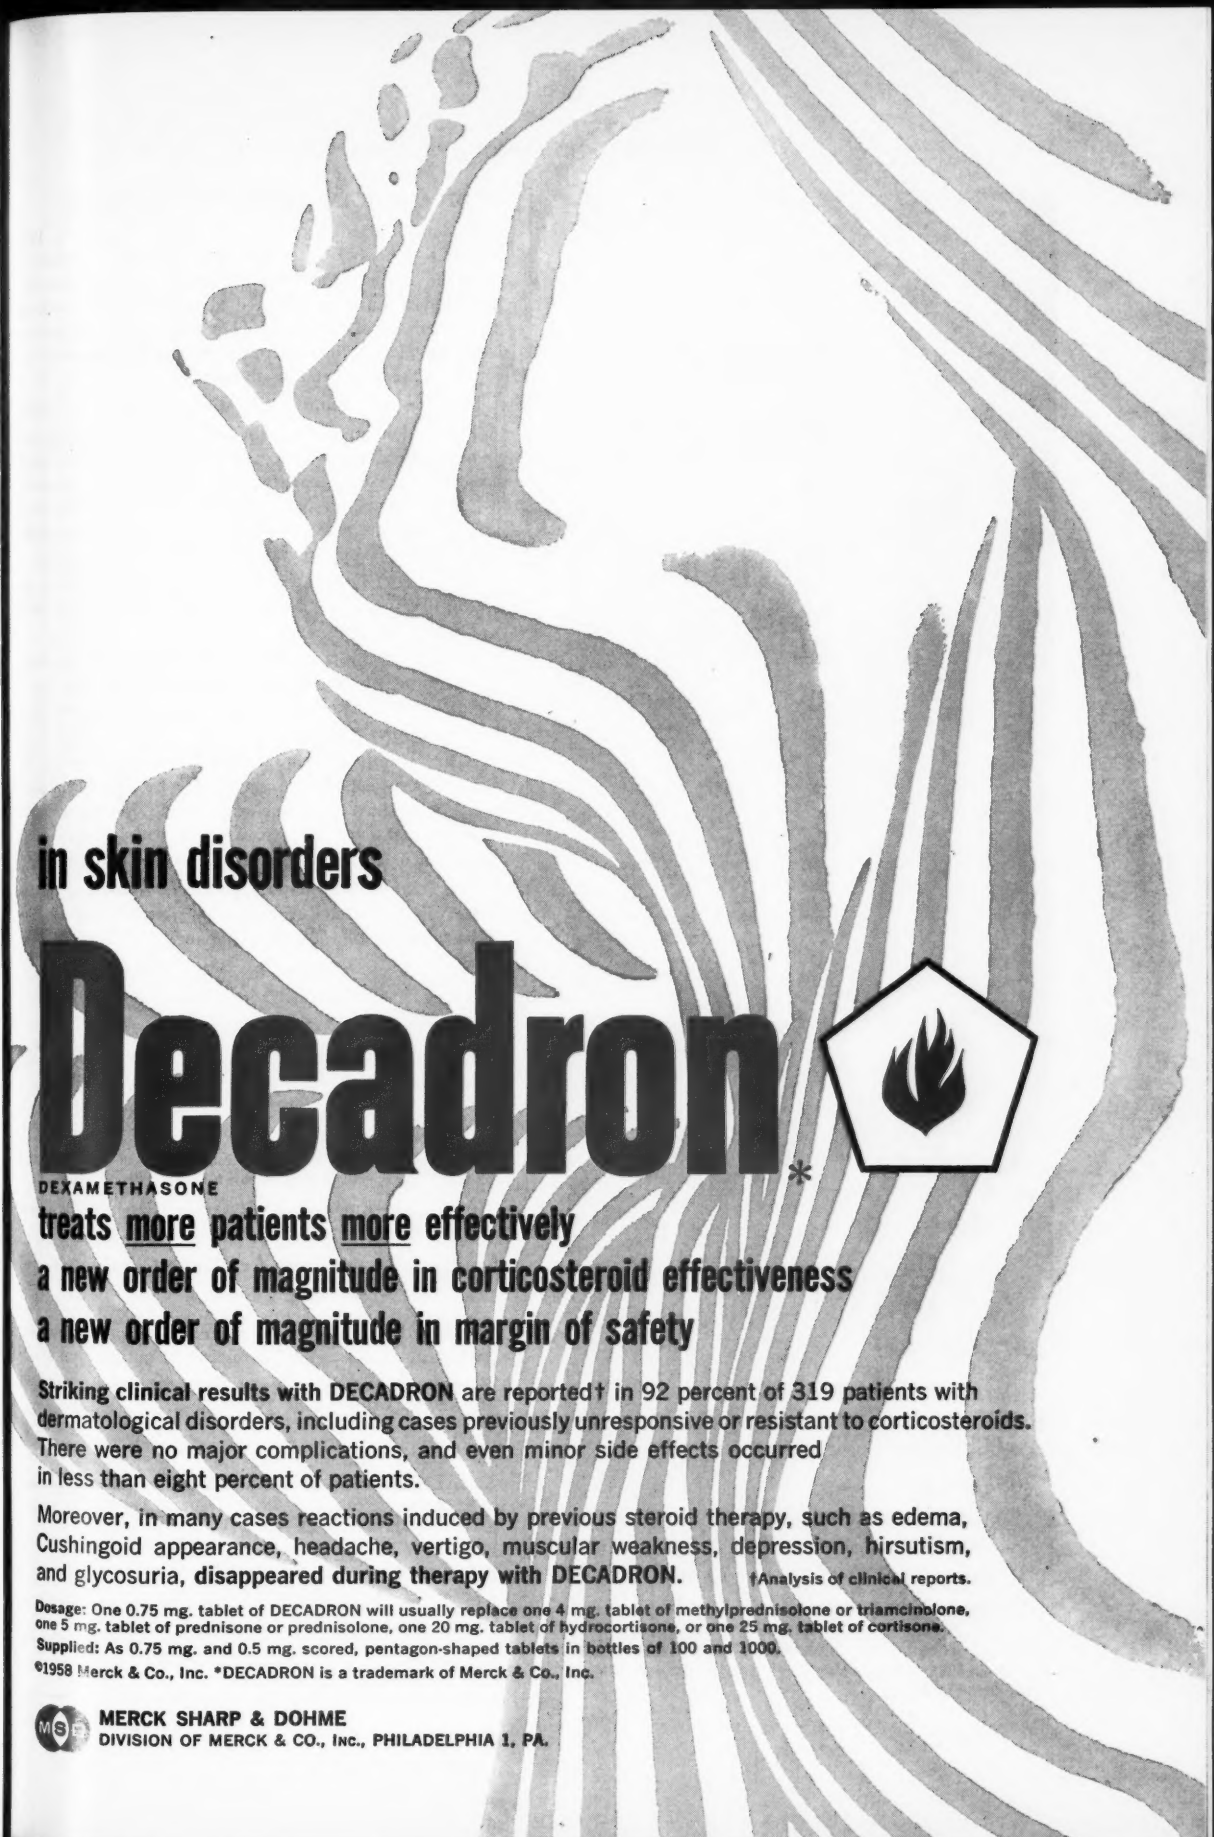
Refresher Course in Allergic Conditions—a full-time course, March 23-25.

Seminar in Internal Medicine—Full-time course, April 6-May 29.

WORLD MEDICAL ASSOCIATION TOUR

Pre-convention tour leaving New York City for Vienna on August 3, 1959. In Vienna, group will attend the Congress on Internal Medicine, then proceed to Kiev, Leningrad, Moscow, Warsaw and Prague (August 8 to 28). Return to Chicago, August 30 to attend Second World Conference on Medical Education; on September 5, travel to Montreal for XIIIth General Assembly of The World Medical Association.

Following the XIIIth General Assembly in Montreal, September 7-12, the tour will leave for Munich, September 13, for attendance at the 18th Congress of International Society of Surgery; visit Vienna, Rome, Barcelona, Madrid and Paris (September 20 to October 12); 8th International Congress on History of Medicine in Barcelona; and return to New York City on October 13, 1959.



PROGRAM ARRANGEMENT AVAILABLE TO COUNTY SOCIETIES

A program on the treatment of arthritis and rheumatic diseases can be arranged for County Medical Societies. The Minnesota State Medical Association and the Minnesota Chapter of the Arthritis and Rheumatism Foundation are co-sponsors. The program can be arranged for one hour or one and a half hours followed by a question-and-answer period.

Two or three speakers will be provided consisting of an orthopedist, physiatrist, and a rheumatologist who is also an internist or pediatrician. A choice of speakers from this state chosen from these specialties will be provided insofar as possible. Substitute speakers will be provided if the speaker who is requested cannot participate. For arrangement of speakers for a county medical meeting, write C. H. Slocumb, M.D., 200 First Street, S.W., Rochester, Minnesota. Allow six to eight weeks when possible to make arrangements.

These programs are being subsidized by the Minnesota Chapter of the Arthritis and Rheumatism Foundation.

in skin disorders
Decadron*
DEXAMETHASONE
treats more patients more effectively
a new order of magnitude in corticosteroid effectiveness
a new order of magnitude in margin of safety
Striking clinical results with DECADRON are reported† in 92 percent of 319 patients with dermatological disorders, including cases previously unresponsive or resistant to corticosteroids. There were no major complications, and even minor side effects occurred in less than eight percent of patients.
Moreover, in many cases reactions induced by previous steroid therapy, such as edema, Cushingoid appearance, headache, vertigo, muscular weakness, depression, hirsutism, and glycosuria, disappeared during therapy with DECADRON.
†Analysis of clinical reports.
Dosage: One 0.75 mg. tablet of DECADRON will usually replace one 4 mg. tablet of methylprednisolone or triamcinolone, one 5 mg. tablet of prednisone or prednisolone, one 20 mg. tablet of hydrocortisone, or one 25 mg. tablet of cortisone.
Supplied: As 0.75 mg. and 0.5 mg. scored, pentagon-shaped tablets in bottles of 100 and 1000.

MEDICAL SOCIAL WORK SCHOLARSHIPS

Students attending any approved graduate professional school of social work offering a medical social field work placement are eligible for scholarships. The student must be accepted for admission by a school accredited by the Council on Social Work Education but may file application for a scholarship pending acceptance for admission to the school.

Deadline for filing applications is April 1, 1959.

The student must have the intention of including the medical social field work placement in his educational program and of completing his study for the Master's degree. Scholarships are ordinarily offered for the final year of the graduate program, but a few scholarships are awarded to well-qualified students for both years.

Applicants must be citizens of the United States or have filed a petition for naturalization. The age limit is thirty-eight.

Scholarship awards are based on the needs of students and will ordinarily include financial assistance for maintenance and for tuition. No allowance for fees will be made.

A new scholarship program for students entering the junior year of college and planning to prepare for medical social work has just been announced. For information relative to this program, students are advised to consult the Dean of any college or university they are attending.

For further information on either program, please write: The National Foundation, Department of Professional Education, 800 2nd Avenue, New York 17, New York.

CONTINUATION COURSES

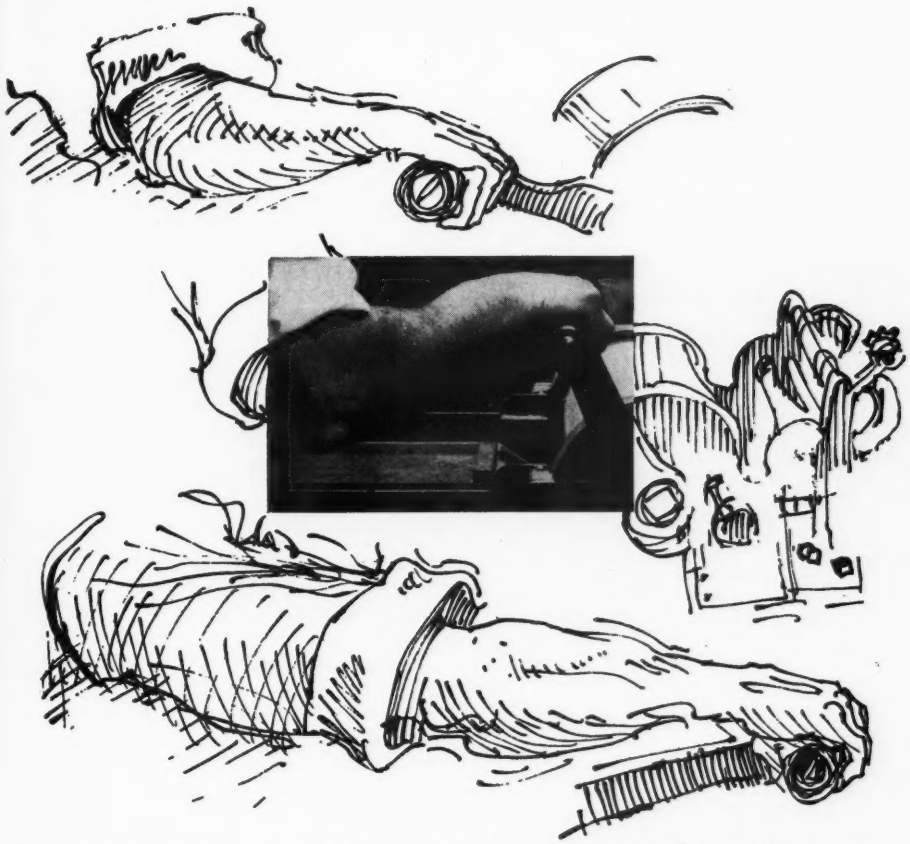
Medical continuation courses to be presented at the Center for Continuation Study, University of Minnesota, are as follows:

March 30-April 3—Basic Concepts of Water and Electrolyte Balance for General Physicians

April 2-4—Emergency Surgery for General Physicians

April 6-8—Radiology for General Physicians

April 16-18—Allergy for General Physicians and Specialists



For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14, Minnesota.

MINNESOTA STATE MEDICAL ASSOCIATION

Annual Meeting

Duluth

May 25-27, 1959

To the relief of musculoskeletal pain, new MEDAPRIN* adds restoration of function

Analgesics offer temporary relief of musculoskeletal pain, but they merely *mask* pain rather than getting at its *cause*. New Medaprin, in addition to bringing about prompt subjective improvement, promotes the *restoration of normal function* by suppressing the inflammation that *causes* the pain.

Medaprin, Upjohn's new analgesic-steroid combination, contains aspirin plus Medrol,** the corticosteroid with *the best therapeutic ratio in the steroid field.*† Instead of suffering recurrent discomfort because of the "wearing off" of analgesics, the patient on Medaprin experiences a smooth, *extended* relief and more normal mobility.

Indications: Medaprin is indicated in mild-to-moderate rheumatic and musculoskeletal conditions, including rheumatoid arthritis, deltoid bursitis, low back pain, neuralgia, synovitis, fibromyositis, osteoarthritis, low back sprain, traumatic wrist, sciatica, and "tennis elbow."

Dosage: The recommended dosage is 1 tablet q.i.d. The usual cautions and contraindications of corticotherapy should be observed.

Supplied: In bottles of 100 and 500.

Formula: Each Medaprin tablet contains

- 300 mg. acetylsalicylic acid, for prompt relief of pain
- 1 mg. Medrol, to suppress the causative inflammation
- 200 mg. calcium carbonate, as buffer

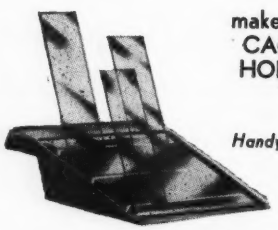
Communications

In a recent issue of MINNESOTA MEDICINE, Volume 42, page 14, January, 1959, comment has been made by Drs. Winkelmann and Brunsting of chelation therapy in Scleroderma.

I should like to call attention to an important distinction in the drug used by these authors. The article states ". . . the use of edathamil disodium (Calcium disodium) versenate by intravenous infusion." Edathamil disodium, prepared by the Abbott Company, is not calcium disodium versenate. Edathamil disodium, the drug exhibited in the authors' cases, is a member of a fairly broad group of the ethylenediamine terta-acetic acid series. I do hope that your Journal will emphasize this observation.

May I likewise call attention to our encouraging results in the treatment of acrosclerotic scleroderma by means of Edathamil (Na_2-EDTA) reported in the *Journal of Investigative Dermatology* (Rukavina, J. G. et al, Vol. 29:273-287, October, 1957; and Price, J., M.D., Ph.D., et al, Vol. 29:289-298, October, 1957).



In this series of publications, we reported not only the clinical results in a series of cases, but also emphasized an apparent biochemical aberration in tryptophan metabolism in these subjects—a fault heretofore not described. We likewise reviewed the chemistry and pharmacology of these compounds and their possible application in clinical medicine.

JOHN G. RUKAVINA, M.D.

"Everything for the Physician"

FOR FAST SERVICE CALL CA. 2-1843

Brown & Day, Inc.
62-64 East 5th Street
St. Paul 1, Minnesota

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

Thank you for sending me the copy of MINNESOTA MEDICINE for January, 1959, which contains the editorial that I prepared.

May I congratulate you at once on the quality of MINNESOTA MEDICINE. This is the first time in some years that I have looked it over carefully. Certainly it would rank now as among the best, if not the best, of the state medical journals.

The quality of the typography, the diversification of content, and the up-to-dateness of its news all speak in favor of its usefulness as a state medical journal. Because of the quality of clinical study and research done in the state of Minnesota, your original contributions have a high rating in my estimation.

I have read the whole issue carefully and I found only two typographical errors, although there may be more. . . .

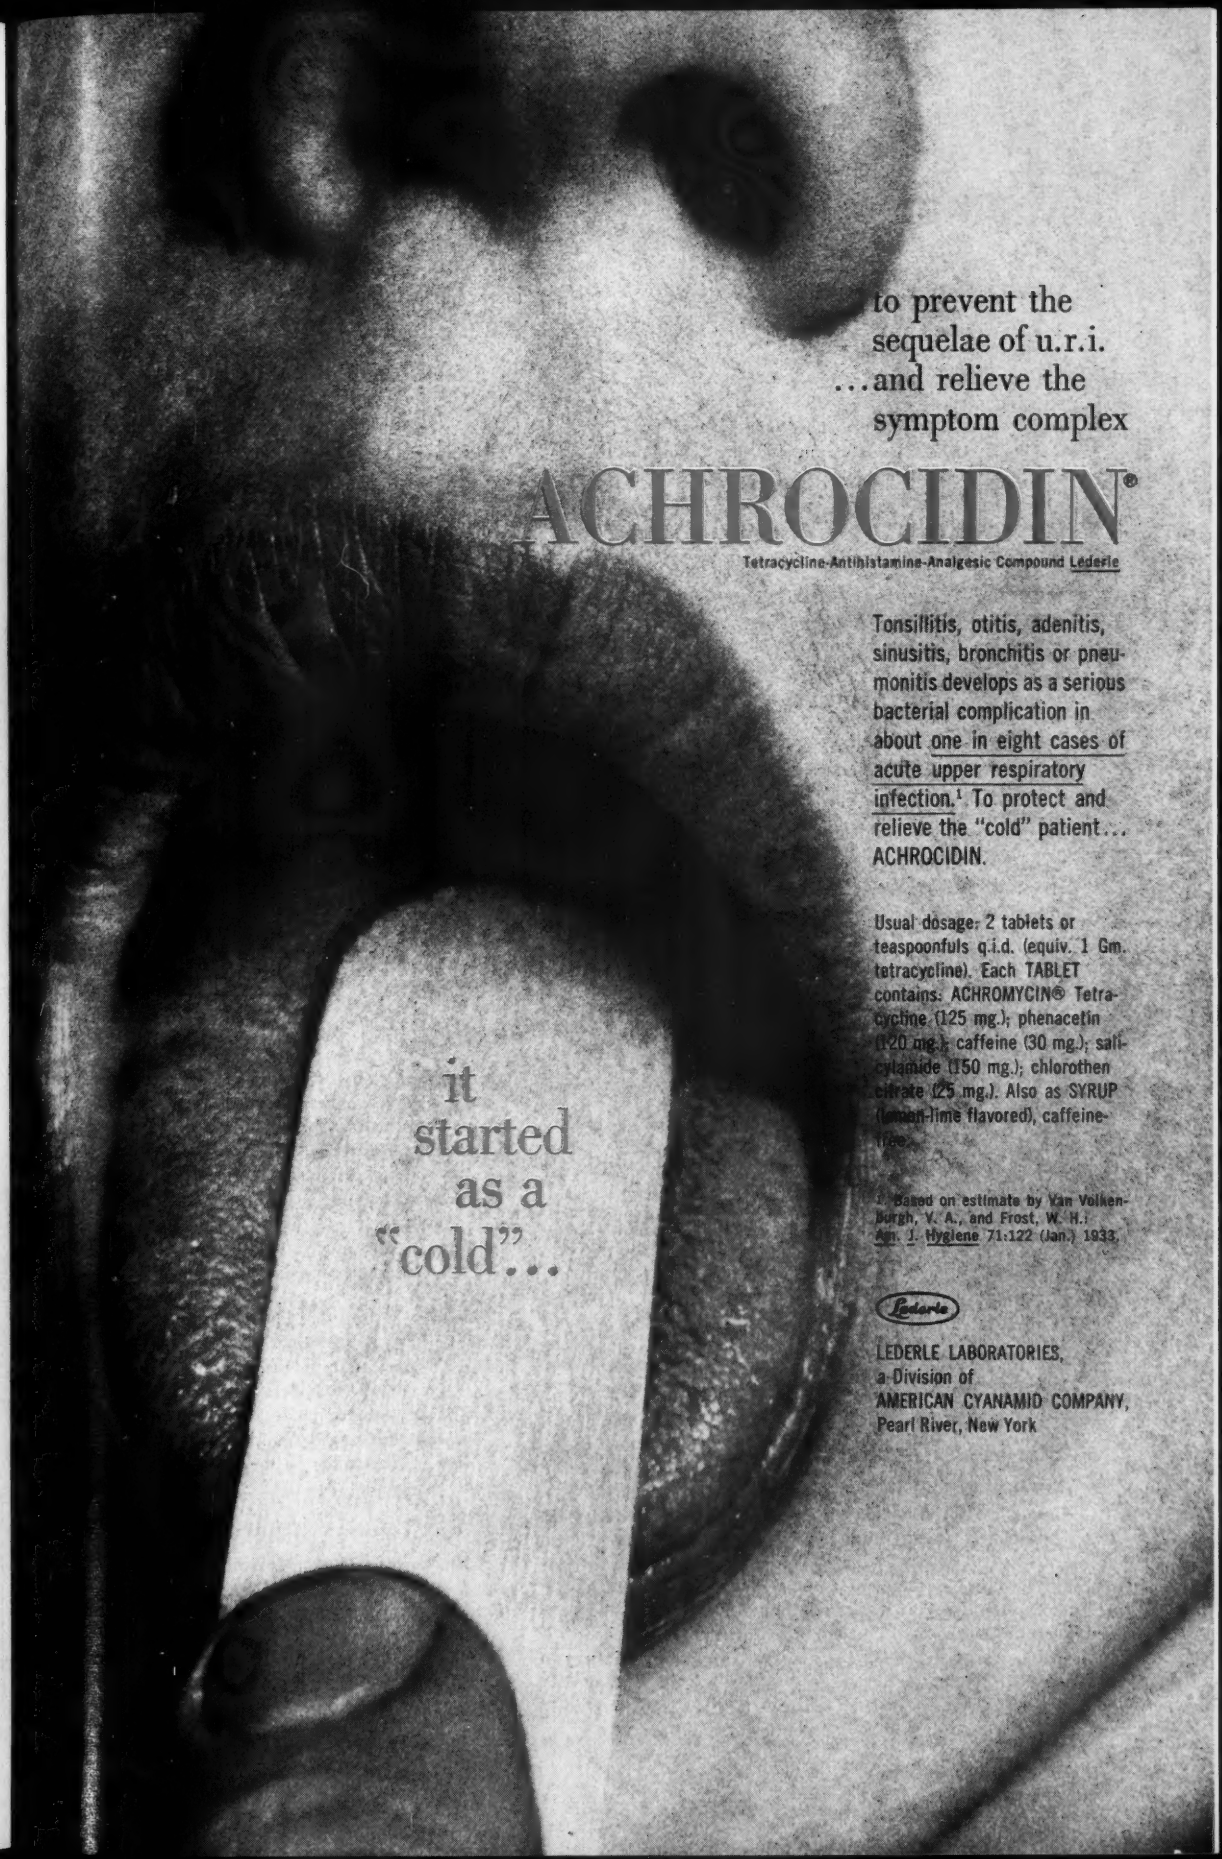
With my best wishes,

Sincerely yours,
MORRIS FISHBEIN

Chicago, Illinois
February 3, 1959

* * *

Congratulations on the handsome changes made in your journal. You have produced a feeling of freshness and vitality which will be enjoyed by your readers. I am sure that you have received many compliments by this time.



Competition in the state and regional journal group is getting tough. Some very fine jobs are being done and now you have moved up among the leaders. Nice going.

Sincerely,
H. L. HARTLEY, M.D.
Editor, Northwest Medicine

Seattle, Washington
February 5, 1959

Is there any special "trick" to leg bandaging as an aid to treatment of refractory cardiac failure?

Yes. Perhaps the most important factor is proper timing, it has been found. The most propitious time to bandage and elevate the legs is on the day when a mercurial injection is administered. This has reportedly helped to increase the extent and duration of diuresis. However, for optimum effect, the physician is advised to observe the precaution of waiting for definite diureses to be well started before proceeding with the bandage.

to prevent the sequelae of u.r.i. ...and relieve the symptom complex

ACHROCIDIN®

Tetracycline-Antihistamine-Analgesic Compound Lederle

Tonsillitis, otitis, adenitis, sinusitis, bronchitis or pneumonitis develops as a serious bacterial complication in about one in eight cases of acute upper respiratory infection.[1] To protect and relieve the "cold" patient... ACHROCIDIN.

Usual dosage: 2 tablets or teaspoonfuls q.i.d. (equiv. 1 Gm. tetracycline). Each TABLET contains: ACHROMYCIN® Tetracycline (125 mg.); phenacetin (120 mg.); caffeine (30 mg.); salicylamide (150 mg.); chlorothen citrate (25 mg.). Also as SYRUP (lemon-lime flavored), caffeine-free.

Woman's Auxiliary

MAKE ANNUAL MEETING PLANS NOW

The Woman's Auxiliary to the Minnesota State Medical Assocation, will hold its thirty-seventh annual convention at Duluth, on May 25, 26, and 27. Headquarters for the convention will be the Hotel Duluth, and registration will be held on the mezzanine floor.

The Executive Board's annual meeting and luncheon will be held on Monday, May 25, at the Kitchi Gammi Club. This meeting will commence promptly at 10:30 a.m., and is open to any member of the Auxiliary who wishes to attend.

A tea is planned for Monday afternoon, May 25, at 3:00 p.m., at the Tweed Art Gallery on the University of Minnesota Duluth Branch Campus. All visiting women will be the guests of the Woman's Auxiliary to the St. Louis County Medical Society.

The annual meeting of the state auxiliary will be held on Tuesday, May 26, at 9:30 a.m. in the Arrowhead Room at the Hotel Duluth. Following the meeting is the annual luncheon, 1:00 p.m., at which Mr. Eugene R. Lambert, former Mayor of Duluth, will speak. His topic will be "What the Seaway will mean to Minnesota."

Tuesday evening at 7:00 p.m., the banquet for doctors and wives will be held in the ballroom of the Hotel Duluth.

Concluding the auxiliary activities will be a "round-up" breakfast at the Duluth Women's Club, planned for Wednesday, May 27, at 10:30 a.m.

More specific information will be published prior to the meeting, but it is anticipated that this "preview" will stimulate many members to make plans to attend this well-planned convention at Duluth.

MID-WINTER BOARD MEETING SUCCESSFUL

The annual mid-winter board meeting of the Woman's Auxiliary to the Minnesota State Medical Association was held February 2, 1959, in the Women's City Club in St. Paul.

Guest luncheon speaker was Dr. E. W. Ziebarth, radio news analyst. He presented an illustrated lecture concerning his recent trip to Russia.

Chairman in charge of the arrangements for the event was Mrs. William Von der Weyer. Hostesses helping her were Mrs. Harold Peterson, Mrs. Leo Nash and Mrs. Grant R. Diessner.

RAMSEY COUNTY BOARD ENTERTAINS

Members of the Woman's Auxiliary to the Ramsey County Medical Society were guests when "Luncheon-Varieties '59" was presented by the auxiliary board in the Women's City Club in St. Paul recently.

The event began with a social hour and noon luncheon. Mrs. Douglas R. Kusske and Mrs. James R. Ralph were in charge of the program featuring a skit by board members. Mrs. William Menold and Mrs. Jack Murphy handled reservations.

RED CARNATION BALL HONORS DOCTOR HUSBANDS

Saturday, February 7, was the date of the annual Red Carnation Ball given by the Woman's Auxiliary to the Hennepin County Medical Society to honor their husbands. Two hundred and thirty doctors and their wives attended the party at the Interlachen Country Club. One of the high spots of the party each year occurs when each wife pins a red carnation on her husband's lapel. This tradition had its origin from the deep south where the red carnation was given as a token of appreciation by patients on a day specified as "Doctor's Day."

This year, the ball had a valentine's motif. The profusion of valentine hearts made of red, white and pink ribbon bows most artistically and effectively complemented the traditional red carnation theme.

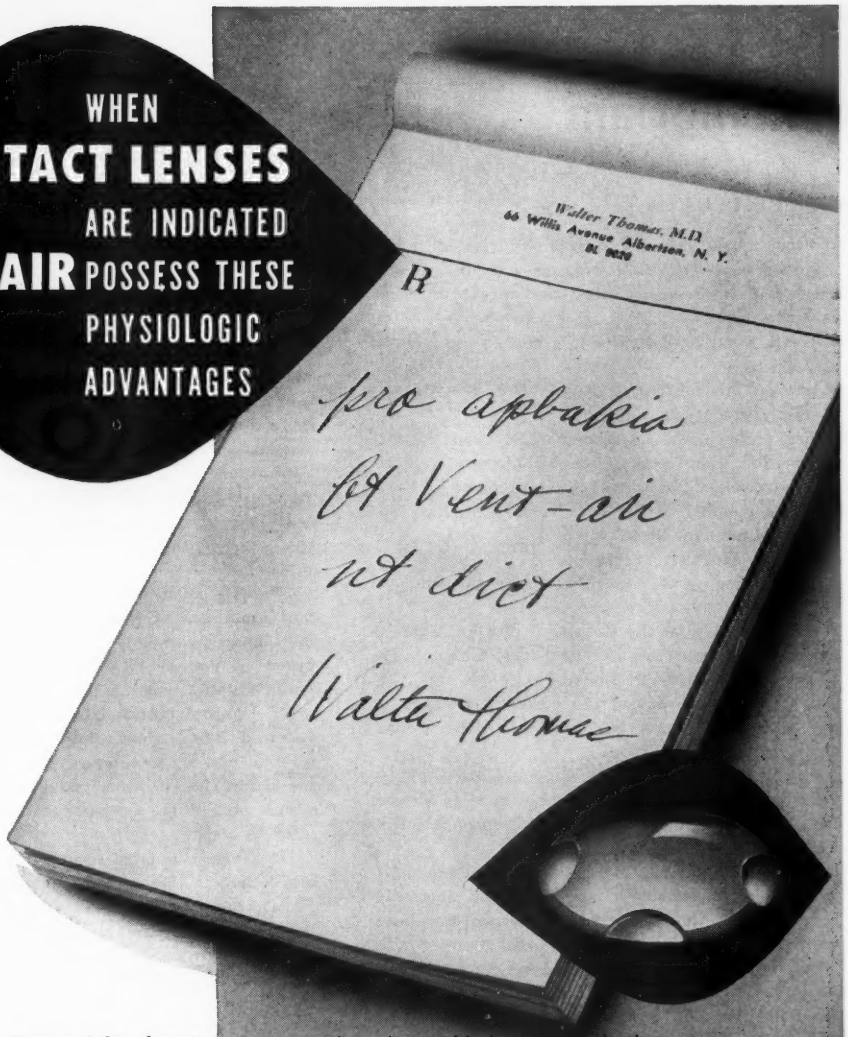
Chairmen of the decorations and all arrangements for the ball was Mrs. Robert G. Tinkham. The Auxiliary extends its congratulations and appreciation to Mrs. Tinkham and her committee for this most beautiful and memorable occasion.

ST. LOUIS COUNTY AUXILIARY ACTIVITIES

The St. Louis County Medical Auxiliary began its year with the customary business meeting, followed by a membership tea.

The topic for the November meeting was "Health Facilities in St. Louis County, How Administered and How Financed." Mr. Ove Wagensteen discussed the subject most interestingly and informatively.

In January, ten Auxiliary members brought as their guests a potential or new member. The program consisted of a tour of the Leonardo da Vinci exhibit, "Models of Inventions," with a commentary by Mr. William Boyce of the University of Minnesota, Duluth Branch Art Department. The exhibit was on display at the new Tweed Art Gallery, which added to the interest of the program.



In addition to a rummage sale in the fall, which netted $300.00, other accomplishments have included: three nurses scholarships, totaling $400; $150 for AMEF; twenty-one subscriptions to *Today's Health* for Duluth schools and institutions; preparation of refreshments for a USO party; and donations to most of the Auxiliary philanthropic commitments.

Also, Auxiliary members staffed and were responsible for Stork Photography at St. Luke's Hospital, which is a part of the Ladies Guild volunteer program. From the first of September to the first of January, this group of workers made $374.07 for the Guild.

MOWER COUNTY HOLDS CAREERS DAY

The Mower County Medical Auxiliary recently sponsored its annual program to give high school girls of that area career information on nursing and medical sciences. An estimated 175 Austin High School and Pacelli High School students participated in the program.

WHEN
CONTACT LENSES
ARE INDICATED
VENT-AIR POSSESS THESE
PHYSIOLOGIC
ADVANTAGES

Four peripheral vents	Permit topical circulation of lachrymal and glandular secretions without excessive motility
Corneal apical clearance	Favors normal corneal metabolism and oxygenation
Ultra-Smoothness of Inner and Outer Surfaces	Avoid limbal epithelial and tarsal conjunctival exacerbation
Highly absorptive methyl-methacrylate composition	Simulates "wetting" and moisture-retention properties of cornea (of military specification)
Precision-ground	Prescriptive qualities exact to ± 0.12 D. with precise allowance for vertex refraction and lachrymal factor (exact to .02 mm radius in inner curvature)
Custom-fitted	In uni-, bi-, or tri-curve radii conforming to corneal peripheral asphericities
Hyper-thinness of edge or center	Maintains uniform thickness in high myopia or hyperopia approximating .20 mm irrespective of power
Widest range of inner radii	From 5.0 to 10.00 mm providing for extremes of keratoconic and megaloglobic dimensions
Cosmetic, pin-hole and tinted effects	For leucomatous, polyopic, iridodialytic and albinic conditions or other corneal or media anomalies.

In Memoriam

FREDERICK U. DAVIS

Dr. Frederick U. Davis, Faribault physician, died Friday, January 23, 1959, following an extended illness. The deceased was eighty-three years old at the time of his death.

Dr. Davis, a native of Faribault, served in the Spanish American War.

He received his medical education from the University of Minnesota Medical School.

His first practice was established in St. Clair, Minnesota. In 1906, Dr. Davis moved his practice to Faribault and continued there until his retirement in 1937.

He was a member of the Rice County Medical Society, the Minnesota State Medical Association, and the American Medical Association.

He had served as Health Officer for the City of Faribault for a number of years.

He was a member of the Cathedral of Our Merciful Saviour and had served on the Cathedral Chapter. He was a member of Faribault Lodge No. 9 AF and AM. He was a charter member of the Faribault Chapter of Rotary International and had served as the second President of that organization.

He was also a member of the William Kane Camp—United Spanish American War Veterans. He served for many years as the head of the Rice County Selective Service Board.

Dr. Davis was a moving figure in the development of the Boy Scout movement in the Faribault area. He had served as the Area Council President and had been instrumental in bringing about the affiliation of this area with the National Boy Scout Movement. He was an honorary life member of The Indian Head Council—Boy Scouts of America, and he was the recipient of the Silver Beaver Award for distinguished service to boyhood.

Dr. Davis is survived by his wife Erna; by two sisters, Miss Alice Davis and Miss Katharine Davis, Minneapolis; and by a niece Miss Elizabeth Redway, Tacoma, Wash.

ADOLPH M. HANSON

Dr. Adolph M. Hanson, Faribault physician, died January 15, 1959. He was seventy years old at the time of his death.

For more than forty-five years, the deceased had practiced medicine in Faribault.

He was born in St. Paul, Minnesota, and received his early education at Red Wing Seminary. He obtained his premedical and medical education at the following colleges and universities: Hamline University, University of Minnesota, Northwestern University and the University of Pennsylvania School of Neurosurgery, where he did graduate work. Dr. Hanson also received an A.B. degree from St. Olaf College, Northfield in 1922, a Masters Degree in 1923 and an Honorary Doctor of Science Degree in 1943.

He began practice of medicine in Red Wing in 1911 and moved to Faribault in 1912.

For many years, Dr. Hanson was in charge of the Hanson Research Laboratory in Faribault, which specialized in the research of glands of internal secretion.

He served as Neurosurgeon, Evacuation Hospital, 8 A.E.F., World War I. He was a member of Rice County Medical Society, the Minnesota State Medical Association and the American Medical Association. In addition, he was a member of the American Chemical Society, Association of Military Surgeons of the United States, Association for Study of Internal Secretions, and the American Medical Editors and Authors Association.

He was awarded first prize for work on the parathyroid gland by the Minnesota Society of Internal Medicine in 1927.

He was the author of "Practical Helps in the Study and Treatment of Head Injuries" 1925; also a chapter on Management of Gunshot Wounds of the Head and Spine, in Volume XI, The Medical Department of the United States Army in the World War.

Dr. Hanson contributed numerous articles on parathyroid and thymus glands, head, spine and superficial nerve surgery, and other subjects. He was the discoverer of the parathyroid thymus and pineal active extracts; inventor of a dural separator and bone elevator used in brain surgery.

Dr. Hanson donated scientific equipment of the Hanson Research Laboratory to the chemistry department of St. Olaf College in Northfield in July, 1942, to be perpetuated as a special laboratory for advanced study.

He is survived by his wife, Lucille; three daughters, Mrs. Joseph Kuhlmann (Jane) Irvington-on-Hudson, N. Y.; Mrs. George Holdy (Anne) Minneapolis and Mrs. Charles Synder (Patricia) North Branford, Conn.; a son, Adolph Hanson, St. Paul; a brother, George Hanson, Kenyon, nine grandchildren and one great grandchild.

EDWARD A. MEYERDING

Dr. E. A. Meyerding, retired Executive Secretary of the Minnesota Tuberculosis and Health Association, died January 23, 1959. He was eighty years of age at the time of his death.

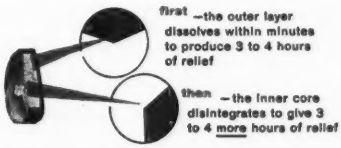
From 1924 to 1937, he served as executive secretary of the Minnesota State Medical Association. Dr. Meyerding, who served as director of hygiene for the St. Paul Public Schools from 1909 to 1924, was frequently referred to as St. Paul's first "school physician."

In 1956, Dr. Meyerding received the William G. Anderson award of the American Association for Health, Physical Education and Recreation, for his work with Minnesota school children.

He was a native of St. Paul and received his early education at Mechanic Arts High School. A graduate of the University of Minnesota School of Medicine, he

(Continued on Page 300)

running noses and open stuffed noses orally



with TRIAMINIC, the oral nasal decongestant

- in nasal and paranasal congestion
- in sinusitis
- in postnasal drip
- in allergic reactions of the upper respiratory tract

safer and more effective than topical medication

- reaches *all* respiratory membranes systemically
- avoids "nose drop addiction"
- presents no problem of rebound congestion
- provides longer-lasting relief

Relief with Triaminic is prompt and prolonged because of this special timed-release action . . . beneficial effect starts in minutes, lasts for hours.

Each* TRIAMINIC *Tablet provides:

Phenylpropanolamine HCl . . .	50 mg.
Pheniramine maleate	25 mg.
Pyrilamine maleate	25 mg.

One-half of this formula is in the outer layer, the other half is in the core.

Dosage: One tablet in the morning, mid-afternoon and in the evening, if needed.

Triaminic®

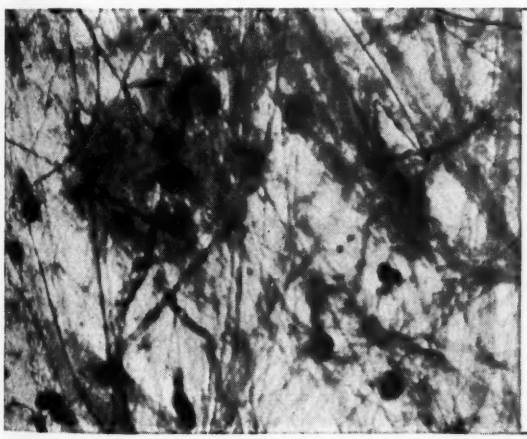
Also available: For the occasional patient who requires only half dosage: timed-release TRIAMINIC JUVELETS. Each Juvelet is equivalent to ½ of a Triaminic Tablet.

For those patients who prefer liquid medication: TRIAMINIC SYRUP. Each 5 ml. tsp. of this palatable syrup is equivalent to ¼ of a Triaminic Tablet.

SMITH-DORSEY • a division of The Wander Company • Lincoln, Nebraska • Peterborough, Canada

NOW—YOU CAN GET THE
UNSURPASSED ADVANTAGES
OF ARISTOCORT
IN SALICYLATE
COMBINATION

Aristo



Aristogesic combines the *anti-inflammatory* effects of Aristocort® Triamcinolone with the *analgesic* action of a most potent salicylate. This means that the dosage of each is *substantially lower* than that ordinarily required for each agent alone. With Aristogesic the physician has exceptionally wide latitude in adjusting the dosage to the lowest effective level.

The possibility of gastric distress from either salicylamide or corticosteroid is minimized because of lower dosage required. This is further reduced by the buffer action of aluminum hydroxide. And the ascorbic acid helps meet the increased need for this vitamin in stress conditions. Because of the low dosage, side effects with Aristogesic have been relatively infrequent and minor in nature. However, more serious side effects have traditionally been observed on all corticosteroid therapy. Patients on long-term Aristogesic therapy should, therefore, be observed carefully.

ogesic*

Steroid—Analgesic Compound LEDERLE

for relief of *chronic*—but *less severe* pain of rheumatic origin

Indications: Mild cases of rheumatoid arthritis, tenosynovitis, synovitis, bursitis, mild spondylitis, myositis, fibrositis, neuritis and certain muscular strains.

Dosage: Average initial dosage: 2 capsules 3 or 4 times daily. Maintenance dosage to be adjusted according to response.

Each Aristogesic Capsule contains:

ARISTOCORT® Triamcinolone . . . . 0.5 mg.
Salicylamide . . . . 325 mg.
Aluminum Hydroxide . . 75 mg.
Ascorbic Acid . . . . . 20 mg.

Supply: Bottles of 100.

this economical
P&H *TREATMENT TABLE*
meets the need for efficiency and high quality

STURDY—FINELY CONSTRUCTED—MADE OF GENUINE CANADIAN BIRCH

With the growth of the medical clinic there has come the need for a new type of table. The P&H TREATMENT TABLE meets that need with both style and economy. We know you will agree that this is the best table value in years. It is a quality table that you will be proud to own and will, we are sure, find it an excellent table for your "second" examination room.

This sturdily constructed table is made of the finest genuine Canadian Birch—solid wood legs and rails with birch-face five-ply panels for drawer and door fronts. It is offered in one standard finish only—natural wood in a golden blond color. It has six drawers and one compartment accessible from either side. There is a three position headrest, sliding stirrups, sliding leg rest and foot step. Upholstered with brown DuPont Fabrilite with 2" of padding.

DIMENSIONS:
Length 48", fully extended 68", width 22" height 32".

EDWARD A. MEYERDING

(Continued from Page 296)

attended Harvard Graduate School and took special training in Chicago, Boston, and Paris.

In 1917, he served with the United States Army in World War I, and later was promoted to the rank of Colonel in the United States Army Medical Corps.

A member of Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association, Dr. Meyerding was an organizer of the Minnesota Trudeau Society. He was also a fellow of the American College of Chest Physicians.

He is survived by his wife, Eugenie; two sons, Dr. E. V. of Medford, Oregon, and Charles of St. Louis, Missouri; a daughter, Mrs. Robert Linsmayer of St. Paul; and a brother, Dr. Henry Meyerding, of Rochester. There are eight grandchildren.

EDWARD B. TUOHY

Dr. Edward B. Tuohy was born in Duluth, March 17, 1908. He was the son of Dr. Edward L. Tuohy, who has been prominent in medical circles as a physician in his home in Duluth and the state of Minnesota. He died in California on January 12, 1959, at the age of fifty-one years.

Dr. Tuohy attended the University of Minnesota, where he received his Bachelor of Science degree in 1929. He entered the University of Pennsylvania, receiving the degree of Doctor of Medicine in 1932. He served his internship in New York City and at the Ancker Hospital in St. Paul.

On October 1, 1933, Dr. Tuohy went to Rochester, where he was a fellow in medicine of the Mayo Foundation, but in 1935 he transferred his major interest to anesthesiology. In 1935, he was appointed first assistant in anesthesiology, and in October, 1935, he was appointed to the staff of the Mayo Clinic as a consultant in that specialty. He received the degree of Master of Science in anesthesiology from the University of Minnesota in 1936, and was certified as a specialist by the American Board of Anesthesiology in 1939. In 1937, he was appointed an instructor in anesthesiology in the Mayo Foundation; in 1940, he was promoted to assistant professor, and in 1945 to associate professor.

In 1942, he left Rochester for active service in the United States Army Medical Corps, and was stationed at the Walter Reed General Hospital in Washington, D. C., and the Percy Jones General Hospital in Battle Creek, Michigan. He was released to civilian status in 1945 with the grade of Major, and was promoted to the position and grade of Lieutenant Colonel in the reserve corps in 1954.

He returned to Rochester in 1945, resuming his post in the Section of Anesthesiology at the Clinic. He resigned in 1947 to enter private practice in Washington, D. C., where he became professor of anesthesiology at Georgetown University Medical School. In 1951, he moved to Los Angeles to enter the private practice of anesthesiology, and since that time received the appointment of professor of surgery in anesthesiology in the

University of Southern California School of Medicine in 1953. He was a consultant to the United States Naval Medical Center, the United States Public Health Service, and senior consultant to the United States Air Force.

Among the distinctions in his field, he was president of the American Society of Anesthesiólogy in 1947, a member of the Board of Directors of the American Board in 1950-1956, and a delegate from that Board to the House of Delegates of the American Medical Association from 1951-1955. He was also a member of the American Society for Experimental Pharmacology and Therapeutics, the American Association for the Advancement of Science, and the Alumni Association of the Mayo Foundation.

He contributed more than a hundred papers to the medical literature on the specialty he followed.

He is survived by his wife, Dorothy, and three children, Barbara, Michael and Patrick, all of Minneapolis.

LEAFLETS ON PREVENTION OF BLINDNESS REVISED

The Prevention of Blindness Department of the Philadelphia Association for the Blind, Inc., has announced the revision and republication of three of its most popular leaflets: "Why Glasses," "Danger Ahead—Glaucoma," and "Check Your Child's Eyes."

The revision was accomplished by the Health Information and Advisory Committee of the Prevention of Blindness Department. This Committee is composed of representatives from City Health and Safety Agencies; Eye Doctors; Public Relations Agencies; Industry and Public Welfare groups. The Committee meets monthly to consider and advise on all programs sponsored by the Prevention of Blindness Department and periodically reviews the effectiveness of all printed material. Results of a previous survey had indicated that the original three mentioned leaflets could be improved in the interests of getting the message over to the reading public in a more concise and effective manner. The three revised leaflets are now available.

The Association has a series of fourteen leaflets on various subjects of eye care and prevention of blindness. Anyone interested in obtaining free samples of these leaflets, may do so by writing directly to the Philadelphia Association for the Blind, Inc., 100 E. Price St., Attention: Prevention of Blindness Department, Philadelphia, Pennsylvania.

MOTION PICTURE REVIEW BOOKLET AVAILABLE

The tenth annual publication of "Reviews of Medical Motion Pictures" is now available from the Film Library of the AMA. This publication is prepared by the Division of Communications, Department of Medical Motion Pictures and Television, and contains reprints of all reviews published in *The Journal AMA* during 1958.

For fast, complete treatment of vaginal infections

Problem is: she'll wait until discomfort is acute and then expect immediate relief. The answer is Trisert. Trisert preparations contain ALLANTOIN, an effective debriding agent which quickly dissolves heavy mucus often accompanying vaginal infections . . . METHYLBENZETHONIUM CHLORIDE, a quaternary germicide which removes unpleasant odors . . . SUCCINIC ACID, an aid in maintaining optimal vaginal pH . . . 9-AMINOACRIDINE HYDROCHLORIDE which has been included to supplement the bactericidal and trichomonacidal activity of other constituents. Treatment with Trisert Powder will control symptoms fast . . . usually within an hour . . . and provide effective initial treatment for 48 hours. After a second insufflation, the treatment is completed with at home use of Trisert Tablets which will generally bring the infection under complete control within 7 days.

Trisert

TRISERT TABLETS—Patient set, contains bottle of 30 tablets and special inserter. Bulk bottle of 100 tablets.

TRISERT POWDER—Available in 4 gr. individual treatment bottles. 12 to carton.

TRISERT POWDER INSUFFLATOR—Designed for use with Trisert Powder. Its use is urged for maximum efficiency.

Dr. Frank Kiesler was a recent speaker at a mental health study program arranged by the College of St. Catherine Department of Nursing. Dr. Kiesler, director of training in psychiatry at the University of Minnesota, reported on integration in the basic curriculum of medical education.

"SOMEONE WANTS A DOCTOR!"

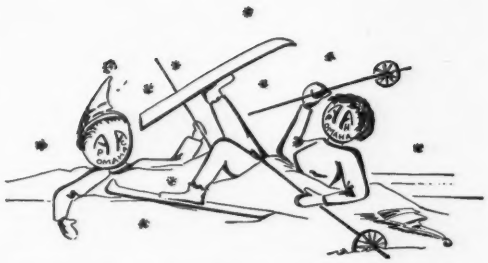
Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

VIRAL AND RICKETTSIAL INFECTIONS OF MAN. Third Edition. Edited by Thomas M. Rivers, M.D. Member Emeritus, Rockefeller Institute, Vice President Medical Affairs, The National Foundation; and Frank L. Horsfall, Jr., M.D., Vice President for Clinical Studies, Physician-in-Chief to the Hospital, The Rockefeller Institute. 967 pages. Illus. Price $8.50, cloth. Philadelphia: J. B. Lippincott Co., 1959.

PHYSICAL DIAGNOSIS—The History and Examination of the Patient. John A. Prior, M.D., Professor of Medicine, Ohio State University, College of Medicine, Columbus; and Jack S. Silberstein, M.D., Clinical Associate Professor of Medicine, Ohio State University, College of Medicine, Columbus. 388 pages. Illus. Price $7.50, cloth. St. Louis: C. V. Mosby Co., 1959.

THE PLASMA PROTEINS. Paul G. Weil, B.A., M.D.C.M., M.Sc., Ph.D. Director of Transfusion Service and Assistant Physician, Royal Victoria Hospital; Lecturer in Medicine, McGill University; Consultant in Medicine, Queen Mary Veterans and Grace Dart Hospitals; Consultant in Transfusion, Queen Elizabeth and Royal Edward Laurentian Hospitals. 133 pages. Illus. Price $3.50, cloth. Philadelphia: J. B. Lippincott Co., 1959.



TUMORS OF THE LUNGS AND MEDIASTINUM. B. M. Fried, M.D., F.C.C.P. Associate Attending Physician, Montefiore Hospital; Associate Visiting Physician, Morrisania City Hospital, New York. 467 pages. Illus. Price $13.50, cloth. Philadelphia: Lea & Febiger, 1959.

MEDICAL DEPARTMENT, U. S. ARMY, IN WORLD WAR II. Volume IV. Communicable Diseases Transmitted Chiefly Through Respiratory and Alimentary Tracts. Edited by Ebbe Curtis Hoff, M.D. Written by twenty-one medical authorities. 544 pages. Illus. Price $5.50, cloth. Washington, D. C.: Office of the Surgeon General, U. S. Government Printing Office, 1958.

CLINICAL OBSTETRICS AND GYNECOLOGY. Vol. 1, No. 4. Symposium on Operative Obstetrics. Edited by J. Robert Willson, M.D. Symposium on Genital Cancer. Edited by Daniel G. Morton, M.D. Illus. Price, $18.00 for series of four volumes, cloth. New York: Paul B. Hoeber, Inc., 1959.

THE INCURABLE WOUND and Further Narratives of Medical Detection. By Berton Roueche. 178 pages. Price $3.50. Boston: Little Brown and Co., 1958.

In six non-sterotyped stories, the author has presented in concise but fascinating detail, the necessary facts of different illnesses and the medical progress thereon. The information contained is of interest to the physician and the laity, especially parents.

LEDERLE LABORATORIES, a Division of AMERICAN CYANAMID COMPANY, Pearl River, New York

These narratives cover a broad scope of medicine. It is this brief insight into everyday problems of Industrial, Psychiatric, Pediatric, Preventive, and Internal Medicine that is contagious to the reader's interest. Although medically technical in a moderate degree, the descriptions clarify the situations for the lay reader without offending the average professional one.

The book is satisfactorily bound on non-glare paper with well-spaced and legible large print.

Perhaps more highly priced than the usual short-story book under 200 pages, this work is a good addition to most public or private libraries.

J. T. GRISMER, M.D.

LESIONS OF THE LOWER BOWEL. By Raymond J. Jackman, M.D., M.S. in Proctology, Head of the Section of Proctology, Mayo Foundation, Graduate School, University of Minnesota, Rochester, Minnesota. 347 pages. Illus. Price $15.50. Springfield, Illinois: Charles C Thomas, 1958.

This book presents, for the first time in words and color photographs, a rather complete story of the common and uncommon lesions of the lower bowel. Although the major emphasis is on diagnosis, there is enough ancillary information to give the reader a fairly comprehensive picture of this field of medicine. Written by a clinician of long experience and excellent judgment, the book is a succinct and honest appraisal of the subject. In an era when proctosigmoidoscopy is assuming its proper role as a diagnostic aid, this volume can be recommended to all physicians. Every chapter is loaded with nuggets of important clinical data that few physicians would be able to glean for themselves.

It is difficult for this reviewer to single out certain chapters for special comment. The chapter on the Technic of Proctoscopy, however, could be called one of the highlights of the book. The Color Atlas which contains a rare and beautiful collection of clinical photographs is outstanding and should be studied by the student and clinician alike.

As a fellow proctologist, this reviewer wishes to thank Dr. Jackman for this meritorious contribution to proctologic literature. This book can be recommended highly to all physicians and students interested in intestinal diseases.

WILLIAM C. BERNSTEIN, M.D.

AMID MASTERS OF TWENTIETH CENTURY MEDICINE; A PANORAMA OF PERSONS AND PICTURES. By Leonard G. Rowntree, M.D. 684 pages. Illus. Price, $11.50. Springfield, Illinois: Charles C Thomas, 1958.

This is an excellent résumé of Dr. Rowntree's experience during his active years in medicine. It is particularly interesting to physicians in Minnesota because of the large amount of space devoted to the time he spent both as Professor of Medicine at the University of Minnesota and Chief of the Division of Medicine at Mayo Clinic.

Dr. Rowntree exemplifies the truly great physicians

whose knowledge was not limited to medicine alone but enveloped all of the allied fields as well as the humanities.

The book is well illustrated, the paper is excellent, and the printing of the usual high quality one expects from the Thomas publishers.

This book makes pleasant reading and relates many interesting and personal anecdotes concerning the great of this century.

JOHN F. BRIGGS, M.D.

CLINICAL OBSTETRICS AND GYNECOLOGY. Quarterly book series, Vol 1, No. 1, March, 1958. Guest Editors: Curtis J. Lund, M.D., Professor of Obstetrics and Gynecology, University of Rochester School of Medicine, and Allan C. Barnes, Professor of Obstetrics and Gynecology, Western Reserve University School of Medicine. Foreword by each editor. 288 pages. Illus. Price $18.00 for four consecutive issues. Cloth. New York: Paul B. Hoeber, Inc., Medical Book Department of Harper and Brothers, 1958.

From the publisher's note and outline of future guest editors and topics, this quarterly will have a symposium on a gynecological subject and one on an obstetric topic each issue. Each will be headed by a guest editor who is outstanding in his specialty and noted for original work and teaching on the subject. Contributors have been asked to describe management details of a specific clinical problem.

Ten papers are presented under the heading of Medical Problems of Pregnancy and eleven titles are considered in the symposium for Management of Endocrine Problems. Contributors to the first issue, for the most part, are recognized authorities of the subject matter presented.

Some controversial topics are presented, and it is stimulating and refreshing to have other view points presented. However, this reviewer must side with one of the guest editors and not agree with all details presented.

The apparent purpose of this publication is neither to duplicate available journals nor to report original work, but rather to outline a practical clinical application for case management. Obviously, many biblographies are limited but do certain necessary references to original papers. A cumulative index is slated to appear in each issue and this quarterly could soon become a handy and up-to-date reference.

Addition of this quarterly solely dedicated to clinical obstetrics and gynecology in practice will be welcomed by the specialist, generalist, and medical student.—JAY R. OLSEN, M.D.

THE FAMILY MEDICAL ENCYCLOPEDIA. Justus J. Schifferes, Ph.D., Director, Health Foundation Council. Formerly Medical Editor, National Foundation for Infantile Paralysis; Associate in Hygiene, Columbia University; Managing Editor, *Modern Medicine*. 617 pages. Illus. Price, $4.95, cloth.

the Health Education Council and author of such books as Healthier Living, How to Live Longer and Science Through the Ages, is purportedly the first book to really meet this need. An ABC of up-to-date medicine, it is three books in one: an authoritative health encyclopedia, an illustrated medical dictionary and a manual of first aid.

The Family Medical Encyclopedia answers the most common and pressing questions about hospitals, modern medicine, health and disease. It is written in words which are easy to understand. The subjects are arranged from A to Z, as in a dictionary, including lucid definitions of those medical terms most frequently used by physicians and nurses when talking to you or your family. In addition, there are comprehensive articles on the most common diseases: arthritis, cancer, diabetes, heart trouble, and many others; on the care and functioning of your body; on preparing yourself to go to the hospital; on health in childhood and old age. Such entries as Health Insurance and Blue Cross cover the economic aspects of medical and hospital care, and the sequence of topics of diet, the digestive system, fat, vitamins and weight — including a separate calorie counter—are particularly helpful.

Although all the information in The Family Medical Encyclopedia has been checked and rechecked by a board of eminent physicians, this book is not intended to replace the family doctor. It tells when a person should go to his physician, and it answers many of the questions that the patient doesn't quite get around to asking his physician. Its common sense information will make medical emergencies less likely. Furthermore, it stresses attitudes towards health, disease, and disabilities which consider psychological as well as physical health.

This is a book to be kept close at hand for quick reference. It is also a fascinating book to browse in, leading the reader to a greater knowledge of medicine today. A completely new and up-to-the-minute work, written in terms that the layman may understand, The Family Medical Encyclopedia is a complete guide to health and medical care for the entire family.

SEA GULLS AND DIURESIS

Sea gulls and other marine birds ingest large quantities of salt from sea water. The salt load would be far too great for the kidneys to handle. But salt-retention edema is prevented by unusual functioning of the nasal (supraorbital) gland, which secretes sodium chloride at higher rates and concentration than the kidney. A cholinergic innervation mechanism, similar to that of salivary glands, is believed responsible. The nerve reflex is thought to depend on a central osmoreceptor, sensitive to the osmotic concentration of the blood. Researchers have found this unusual extrarenal salt excretion in petrels, gulls, penguins, marine ducks and other birds and marine reptiles.

OBSTETRICIAN AND GYNECOLOGIST desires association in group or private practice or office sharing arrangement. Address E-668, care MINNESOTA MEDICINE.

GENERAL PRACTITIONER, age twenty-eight, married, University of Minnesota graduate, completing service obligation in July, 1959, desires association with individual or small group in Minnesota, preferably northern Minnesota. Address E-670, care MINNESOTA MEDICINE.

WANTED—Internist, General Surgeon and General Practitioner with special interest in Obstetrics and/or Pediatrics. Salary on contract basis for one to two years and then eligibility for partnership in a five-man clinic in Minneapolis. Complete clinical facilities with good hospital staff association. Address E-653, care MINNESOTA MEDICINE.

WANTED—Associate in General Practice in Saint Paul. Beginning salary, $10,000, with opportunity for partnership. Address E-663, care MINNESOTA MEDICINE.

WANTED—General Practitioner to take over lucrative unopposed, well-equipped practice in small town, west-central Minnesota. Excellent hunting and fishing area. Will sell or rent—no down payment required. Reasonable terms. Owner specializing. Write E-665, care MINNESOTA MEDICINE.

WANTED—Assistant Medical Director by a large, rapidly growing midwest life insurance company. Prefer young physician with military obligation fulfilled and with some experience in practice or postgraduate training. Liberal group insurance and pension program. Address E-666, care MINNESOTA MEDICINE.

RESIDENCY TRAINING AVAILABLE — Three-year Board-approved residency in Physical Medicine and Rehabilitation in 1,300-bed Veterans Administration Hospital with Baylor University College of Medicine Affiliation. Annual stipend: regular residency $3,250-$4,165; career residency $6,505-$9,890 (stipend dependent upon qualifications). Physicians qualified in specialty of PM&R are in great demand with the VA, private institutions of rehabilitation, private hospitals and private practice. Write Manager, VA Hospital, Houston, Texas.

SOUTHERN MINNESOTA GENERAL PRACTICE available July, 1959. Unopposed, office equipped, home available, specializing. Ideal for new graduate. Write E-667, care MINNESOTA MEDICINE.

OPPORTUNITY to specialize in rapidly growing field of Physical Medicine and Rehabilitation available at Veterans Administration Hospital. If you are under 47, a United States citizen, and graduated from approved medical school, you are eligible for three-year career residency. Yearly salary while in training from $6,505-$9,890 depending upon experience and qualifications. Inquire Chief, Physical Medicine and Rehabilitation Service, Veterans Administration Hospital, Minneapolis, Minnesota.

WANTED: GENERAL PRACTITIONER—To join two men in Southwestern Minnesota town of 4,000. Eventual partnership. Reply with qualifications to: Drs. Hoyer and Dokken, Windom, Minnesota.

WANTED—Orthodontist and/or internists, well-established medical group, Los Angeles area. Twelve thousand dollars annually plus. Early partnership. Opportunity to share in ownership without initial investment. Address E-669, care MINNESOTA MEDICINE.

FOR SALE—Used general surgical, obstetrical, ENT instruments; trial frame, lens case, Stryker cast saw, U.V. light and others. One-fourth to one-third new price. Items sent on approval. Write for itemized list. K. W. Covey, M.D., 908 Thorndale, Crookston, Minnesota.

WORTH INVESTIGATION—Suburban location; will build to sell or lease medical office to your specifications on excellent location next door to new dental clinic. Drug store now under construction across the street. Tom H. Hill, Builder, 3580 Rice Street, Saint Paul 17. Telephone IVanhoe 4-4143.

FOR RENT—Unopposed General Practice, completely equipped. One-year trial basis with option to buy possible. Available July 1, 1959. Owner specializing. Address E-652, Care MINNESOTA MEDICINE.

FOR RENT—Established doctors' clinic in one of Twin Cities' finest location, 2069 Ford Parkway at Cleveland, Highland Park, Saint Paul. Air-conditioned space for two or three doctors available, ground floor. Write Fine Realty Company, 519 Midland Bank Building, Minneapolis 1; telephone FEderal 6-4900 or MIdway 8-4228.

Chemosurgical Treatment of Cancer at the Facial Orifices

FREDERIC E. MOHS, M.D.

Madison, Wisconsin

Associate Professor of Chemosurgery, Department of Surgery, University of Wisconsin, and Director of the Chemosurgery Clinic, University Hospitals.

ALTHOUGH most external forms of cancer frequently send out "silent" extensions into the surrounding tissues, these unpredictable outgrowths are particularly prone to occur in cancers at the facial orifices, namely those of the nose, ears, eyelids, and lips. Since the chemosurgical method, with its complete microscopic control of excision, makes it possible to follow out and destroy these silent outgrowths in a selective manner, the technique results not only in unprecedented assurance of complete removal but also in the preservation of maximal amounts of normal tissues.[1]

Complete microscopic control of excision is accomplished by the systematic use of frozen sections. In order to obtain intact and form-retaining specimens from the entire area under suspicion, it is necessary to produce fixation *in situ* by means of a fixative chemical such as zinc chloride. This chemical, a caustic long used to destroy diseased tissue, was selected after the trial of many fixatives because (1) it is non-toxic systemically in the amounts ordinarily used, (2) it produces adequate fixation with preservation of the microscopic features of the tissues, (3) it has

Presented at the Symposium on Skin Cancer for Dermatologists, University of Minnesota Continuation Center, Minneapolis, October 26, 1957.

no odor, (4) it is safe to handle since it does not readily penetrate the intact skin, (5) it does not damage the healing qualities of the tissues just beyond the limit of fixation, (6) it penetrates well through the tissues and (7) its penetration is accurately controllable when it is incorporated in a paste vehicle of proper design.

The vehicle is composed mainly of a finely granular form of stibnite which is an ore of antimony. A small amount of Sanguinaria canadensis is used as a binder. A satisfactory formula is as follows: stibnite (80 mesh sieve), 40 gm.; Sanguinaria canadensis, 10 gm.; and zinc chloride, saturated solution, 34.5 cc. By varying the depth of application of this paste and the time of its action, the depth of fixation can be accurately varied from a fraction of a millimeter to a centimeter or more.

To determine whether fixative chemicals have any tendency to increase the incidence of metastasis, a group of 114 rats bearing Flexner-Jobling carcinoma was divided into treated and control groups. Repeated, subcurative applications of the zinc chloride fixative were used over a long time in a deliberate attempt to increase metastasis. Instead of an increase, however, there actually was a decrease in the incidence of metastasis to the lymph nodes and lungs from a rate of 41.5 per cent in the control group to a rate of 28 per cent in the treated group. The conclusion that chemical fixation has no tendency to cause cancer to spread has been confirmed by clinical experience in the chemosurgical treatment of nearly 6,000 patients with cancer during the past twenty-one years.

Technique

The chemosurgical technique by which cancer may be excised under complete microscopic control is illustrated by the following report of a case of squamous cell carcinoma of the ear. The neoplasm had grown rapidly to form a large, ulcerated, infiltrative mass which was fixed to the aural cartilages (Fig. 1A).

Local anesthesia was produced by the injection of a 1.5 per cent solution of procaine into the tissues surrounding the neoplasm. Care was used to inject at a sufficient distance from the cancer to be sure that the needle passed through no part of the neoplasm. Then the grossly visible portion of the mass was excised with a scalpel. The cancer tissue was observed to extend to the cartilage and to perforate it in a small area. Hemostasis was secured by the application of dichloracetic acid which also was applied to the skin at the periphery in order to render the stratum corneum permeable to the zinc chloride. A frozen section revealed squamous cell carcinoma, grade 2. The zinc chloride fixative was applied in a depth of about 1 mm. at the periphery and about 0.5 mm. in the center of the lesion. Dressings of cotton and vaselinespread cotton were applied (Fig. 1B). Codeine and aspirin were prescribed as needed for analgesia.

On the next day, a layer of fixed tissue 1 to 2 mm. thick was excised from the entire periphery and from the tissues at the base of the perforation through the cartilage. The area over the rest of the exposed cartilage did not require sectioning because the cartilage was not eroded at any other point. There was no pain or bleeding from the excision of this layer since the incisions were made through fixed tissue. The origin of each specimen was indicated on a map of the lesion on a pad of paper (Fig. 2A) and also by marking on the lesion with mercurochrome (Fig. 1C).

Frozen sections were made through the undersurface of each flat specimen. Less than an hour after the specimens had been removed, the sections were scanned under the microscope by the operator and the areas of cancer were marked on the map (Fig. 2A). Reapplication of the fixative was limited to the areas in which cancer was demonstrated microscopically (Fig. 1C).

On the following day, specimens were removed from the two treated areas and frozen sections were made. Microscopic examination revealed no cancer. The lesion was covered with a dry dressing.

Five days later the final layer of fixed tissue was sufficiently demarcated to permit removal revealing well vascularized granulation tissue (Fig. 1D). The lesion epithelized rapidly (Fig. 1E). There was no recurrence after five years and no metastases developed.

Indications

Although the chemosurgical method may be used to remove most external cancers and many of those in cavities sufficiently accessible to permit the stage-by-stage procedure, the present communication is limited to those around the facial orifices, namely, those of the ear, eyelids, nose, and lips.

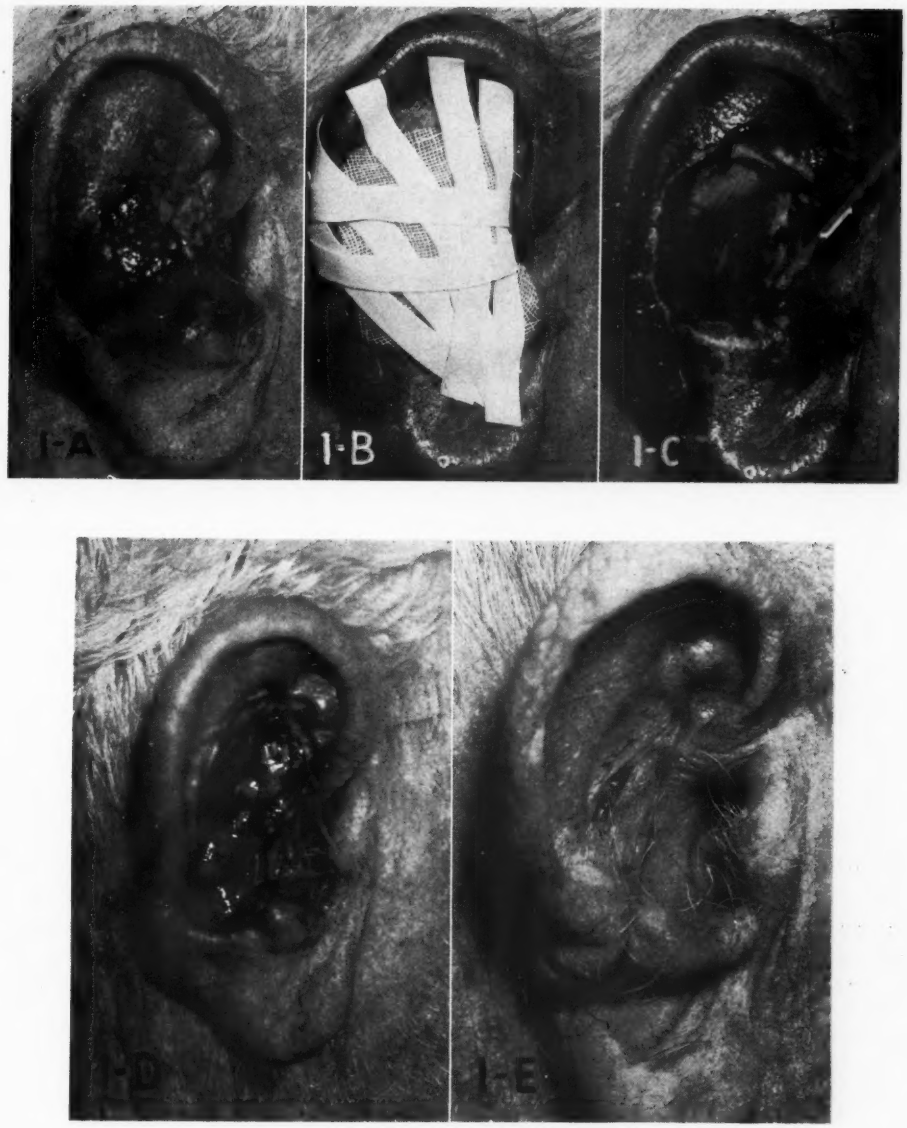

Fig. 1. (A) Squamous cell carcinoma which was adherent to the underlying cartilage. (B) Dressing to hold fixative in place. The main mass had been excised surgically, hemostasis secured with dichloracetic acid and the zinc chloride fixative paste applied. (C) Lesion on the second day. A layer of fixed tissue had just been excised and systematically studied under the microscope by means of frozen sections. The reapplication of the black fixative paste is being limited to the two areas of microscopically-located cancer (Fig. 2A). On the next excision these two areas were microscopically cancer-free (Fig. 2B). (D) Granulation tissue after separation of final layer of fixed tissue. (E) Healed lesion. The patient declined the removal of a small wedge of tissue which was suggested for correction of the irregularity in the outline of the helix. There was no recurrence after five years.

Cancer of the Ear.[2]—As illustrated in Figures 1 and 2, the microscopic control afforded by the chemosurgical method permits sure removal of cancers of the ear and at the same time permits the preservation of maximal amounts of uninvolved tissue. Hence, even though the cancer was fairly extensive, most of the ear was saved.

The removal of carcinomas which deeply invade the helix may result in a sharply-punched-out niche. However, the appearance often can be much improved either by the removal of some of the adjacent tissue to produce a smooth contour or by the removal of a wedge so the defect can be closed. The actual extent of lesions arising on the posterior surface, in the postauricular sulcus, or on the adjacent scalp may be quite unpredictable clinically. Thus, the microscopically guided excisions often reveal silent outgrowths of considerable extent in the surrounding tissues. As in other parts of the ear, the cancer often invades to the level of the cartilage and then extends peripherally on the perichondrium. However, even if quite extensive, lesions in this area usually heal with little visible defect.

Cancers extending inwardly along the external auditory canal are somewhat more difficult to remove chemosurgically because of the small size of the opening. However, by the use of slender instruments the neoplasm can be followed out chemosurgically even though it extends to the middle ear.

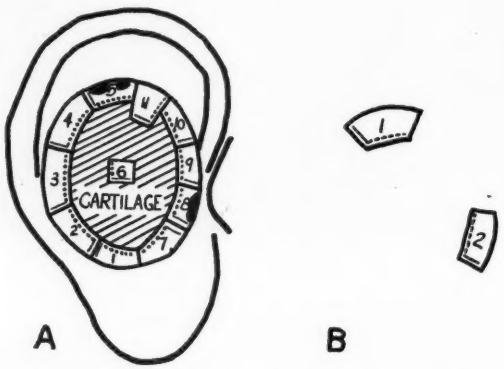

Fig. 2. (A) Map showing origin of the specimens into which the first layer of fixed tissue had been divided. The two solid black areas are the foci of remaining cancer as visualized in the frozen sections. (B) Map of the lesions on the next day. No cancer was found in these specimens.

Cancer of the Eyelids.[3]—A common neoplasm of the eyelids is basal cell carcinoma of the inner canthus (Fig. 3A). Often these send extensions along the periosteum of the medial wall of the orbit or into the adjacent eyelids, but usually the eyeball is not invaded until late. Hence, the chemosurgical removal even of rather advanced neoplasms in this area usually can be accomplished without damage to the bulbus.

In the treatment of eyelid cancer, care must be used to keep the fixative chemical out of the eye. Ordinarily, the grossly visible portion of the neoplasm is removed surgically, the tissues having been anesthetized with procaine. This results in a saucerized depression in which the fixative can be spread and an occlusive dressing applied. The chemosurgical excisions are carried out until they can be carried no further without getting the fixative in the eye. Subsequent layers then are excised surgically and frozen sections made to determine when treatment is complete. The use of unfixed surgical specimens in this manner is feasible when the area being investigated is small,

but it is not practical when larger areas are affected because the unfixed tissues do not retain their shape and they are more difficult to section. After the removal of surgical specimens, the area is cauterized with dichloracetic acid to stop bleeding and to prevent spreading of cancer cells to other parts of the wound.

Cancer of the lower eyelid is treated in much the same way. When the lid margin is affected or closely approached during removal of a cancer it is advisable to remove the full thickness of the eyelid in that area. This produces a niche, but this fills in and the eyelid pulls up into normal position in a remarkable manner. Care must be exercised to avoid leaving excessive conjunctiva at the lid margin because the scar may pull this membrane forward producing an ectropion. When the cancer is several millimeters from the lid margin, however, the elastic eyelid tissues readily stretch so that the contraction of the scar does not produce ectropion.

Cancer of the upper eyelid usually arises well above the lid margin and is relatively easy to treat chemosurgically. If such a cancer invades through the full thickness of the eyelid there is virtually no danger of damage to the eyeball during treatment because the tears dilute the fixative chemical and prevent the formation of harmful concentrations. Of course, if the cancer is so extensive that the removal of the entire upper eyelid is necessary, the excessive exposure of the eyeball may require closure by suturing the lower eyelid to the stump of the upper lid. Lesions at the margin of the upper lid are treated in the same manner as those on the lower lid.

Cancers at the outer canthal region do not have as much room between the rim of the orbit and the eyeball as those at the inner canthus. Hence, as the outer canthal neoplasm becomes more extensive the eyeball becomes correspondingly more vulnerable to invasion. However, unless the sclera is actually invaded by the cancer, the eye usually can be saved by careful chemosurgical excision. In cases in which the eyeball is hopelessly invaded or surrounded by the cancer, the bulbus is removed under local anesthesia and chemosurgical treatment is continued as necessary.

Cancer of the Nose.[4]—Because many cancers of the nose are rather invasive and often send out extensions which are difficult to feel because their consistency closely resembles that of the fibrocartilaginous tissues of the nose, the microscopic guidance provided by the chemosurgical technique is of particular value. Lesions of the alae and nasolabial fold are especially unpredictable (Fig. 4). Alar lesions of moderate extent can be removed with little defect. Those invading the full thickness necessitate the formation of a niche or perforation, but since maximal amounts of well vascularized tissues are preserved, the repair of these defects with composite grafts from the ear is almost always successful.

Advanced lesions may send out extensions for long distances along such structures as the perichondrium, periosteum and embryologic fusion planes. The selective removal of all of these unpredictable extensions may be somewhat laborius, but in such cases it may be the only way to eradicate the cancer. The conservatism which permits preservation of adjacent tissues and structures such as the eyes often is an additional important advantage.

Cancer of the Lip.[5]—Whether of the lower, upper or commissural areas, squamous cell carcinoma of the lips may be reliably and yet conservatively removed by the chemosurgical technique (Fig. 5). Though there frequently are silent extensions of cancer, which may be located unpredictably either in the central or in the peripheral parts of the lesion, the majority of these cancers can be removed so conservatively that little visible scar or defect is produced. Even when the cancer is so extensive that insufficient lip tissue is left for good function, the preservation of appreciable amounts of well vascularized tissue makes it relatively easy to carry out a satisfactory plastic repair. Of course, when metastases are present or suspected, a surgical neck dissection is indicated.

Discussion

The chief advantage of the chemosurgical method in the treatment of external cancer is the unprecedented reliability which results from the microscopic control of excision. Thus, in a consecutive series of 2,019 cases of basal cell carcinoma of the skin the five-year rate of cure was 98.6 per cent, while in a series of 869 cases of squamous cell carcinoma of the skin the rate of cure was 87.8 per cent. Adding both groups together there were 2,888 cases of skin cancer with a five-year rate of cure of 95.5 per cent. The next

best rate of cure in the literature for a similar series of cases was 87.6 per cent which was reported from the Radiumhemmet of Stockholm. In both series, approximately a third of the patients had cancers which previously had been unsuccessfully treated by means of some surgical or radiotherapeutic procedure, and many of the cancers were rather advanced. Similarly, in a series of 533 cases of squamous cell carcinoma of the lips, treatment with chemosurgery resulted in a five-year rate of cure of 92.1 per cent which is well above those reported in the literature.

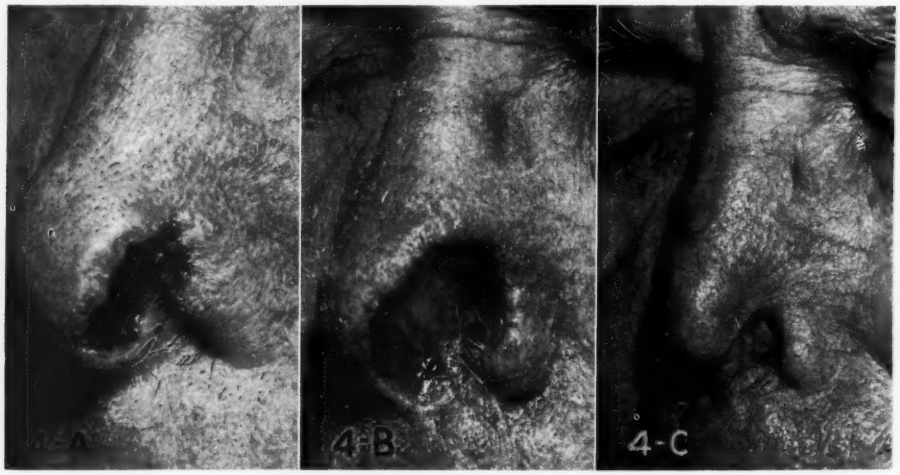

Fig. 4. (A) Basal cell carcinoma which had recurred after eight roentgen and four electrodesiccation treatments. (B) Granulation tissue after chemosurgical excision. (C) Healed lesion. The niche could have been repaired with a composite graft from the ear if the patient had wished it. There was no recurrence after five years.

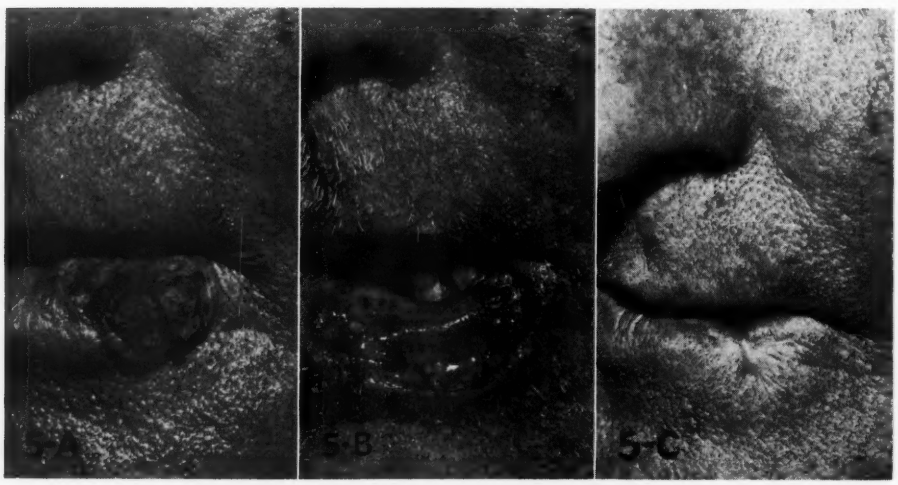

Fig. 5. (A) Squamous cell carcinoma, grade 1, of lower lip. (B) Granulation tissue after chemosurgical excision. Enlarged submaxillary nodes removed in a left suprahyoid neck dissection were reported inflammatory lymphadenopathy. (C) Healed lesion. There was no recurrence after five years.

A second important advantage of the chemosurgical method is the conservatism that can safely be practiced. The microscopic control makes it unnecessary to remove a wide zone of surrounding tissue in order to have reasonable assurance of complete removal. Actually, only 1 or 2 millimeters need be removed beyond the borders of the neoplasm.

Both the reliability and the conservatism are the direct result of the complete microscopic control which makes it possible to follow out the unpredictable extensions of the cancer into the surrounding tissues. In some cases these extensions exhibit a rather selective affinity for certain structures such as the dermis, fascial planes, periosteum, perichondrium, embryologic fusion planes, nerve sheaths, lymph vessels or blood vessels.[6] In other cases there may be no special affinity for particular tissue structures, and yet the cancer may exhibit irregular and unpredictable extensions because of the many variations in the mechanical and nutritive conditions which affect the spread of cancer cells through the tissues. Not infrequently the "silent" outgrowths extend for several centimeters beyond the grossly detectable portion of the mass while lesser degrees of clinically unrecognized peripheral spread occurs in a great majority of cases.

A third advantage of the chemosurgical method is the extremely low operative mortality rate of approximately one-third of one per cent. The lack of need for a general anesthetic and the rarity of infection and other complications are responsible for the safety of the method. This is an important advantage in view of the fact that many patients with cancer are elderly and in fragile health.

A fourth advantage of the chemosurgical method is the fact that the technique permits the extension of operability to a considerable group of patients with cancers too advanced to be amenable to the usual surgical and radiotherapeutic measures.[7]

A fifth advantage is the excellent healing and essential lack of adverse sequelae following chemosurgical treatment. Never does the scar break down or undergo malignant change, and only rarely do keloid scars form.

While the chemosurgical technique is relatively simple in principle, its practice requires special knowledge and special skills which are best attained by special training and which are retained by constant practice. For optimal results, a special clinic with facilities and technical personnel for the preparation of the special type of frozen sections is necessary. Eventually, such a setup should be available in every large center of population.[8]

Summary

The chemosurgical method attains complete microscopic control of the excision of accessible cancer by the systematic use of frozen sections of the tissues which have been chemically fixed *in situ* prior to excision. The microscqpic control is of particular value in the treatment of cancers of the ears, eyelids, nose and lips because in these orificial areas "silent" outgrowths into the surrounding tissues occur especially frequently. Since these unpredictable outgrowths can be excised accurately and selectively, there results an unprecedented assurance of complete removal and yet, only minimal amounts of uninvolved tissues need be removed. Other advantages are the low operative risk, the extension of operability to a considerable number of patients with cancers not amenable to the usual surgical or radiation treatments and the excellent healing with the virtual lack of adverse sequelae. Special facilities and personnel for the use of this method eventually should be available in every large center of population.

Diagnosis and Treatment of Epileptic Disorders

● *The distressed epileptic patient and his family frequently come to the general practitioner for solution of the medical and social problems associated with this convulsive disease. This article outlines aids in diagnosis and emphasizes how the physician can aid the patient to live with his disease if it cannot be completely controlled.*

DONALD W. MULDER, M.D.
Rochester, Minnesota

From the Section of Neurology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

IN the diagnosis and treatment of neurologic disease, the recognition and proper interpretation of epileptic seizures are frequently of crucial significance. Because of its dramatic character, a generalized convulsion rarely leaves any doubt as to what has occurred. Minor seizures may cause much confusion in diagnosis because of the diversity of their symptoms. Yet any seizure, no matter how seemingly inconsequential, is of great significance as a sign of cerebral disease. It has been customary to regard epilepsy as a disease sui generis. My associates and I[1] have found it more useful to think of convulsions as a symptom.

Seizures are brief and stereotyped cerebral storms inappropriate to the immediate situation and followed by transient impairment of cerebral function.[2] The attacks begin abruptly and irresistibly. They usually are initiated by a warning, or aura, lasting for a few seconds. The patient cannot change the pattern of the attack. The seizure itself is brief, usually lasting less than five minutes and often no more than a few seconds. Attacks may occur repeatedly, giving the impression of a prolonged seizure persisting at times for hours or days; this is called "status epilepticus." In any one patient, the seizures are stereotyped, as already indicated, although slight variation may occur with progression of the cerebral lesion. Finally, inhibition of cerebral function follows the seizure and may persist longer than the attack itself. This paralysis commonly is evidenced by coma or a disturbance of the person's higher faculties, so that his mentation is impaired. A temporary postictal hemiparesis, or Todd's paralysis, may result when a seizure arises in the primary motor areas of the cerebral cortex. This may last only a few minutes, but in rare instances it may persist for two or three days. Persistent postconvulsive cerebral paralysis is frequently indicative of severe organic brain disease.

The evaluation of seizures depends on a satisfactory history. The patient himself often is unaware of the exact evolution of his attacks, or he may be embarrassed by his symptoms and prefer not to discuss them. Therefore, part of the history must be obtained and verified by witnesses to an attack. The attack may so frighten observers that they cannot give a reliable account of it; thus, it is often desirable to summarize the description of several witnesses.

As already noted, a seizure is only a symptom. Therefore, the decision that a patient has a convulsive disorder does not indicate that a diagnosis has been made but rather that the investigation has begun. Since a seizure results from episodic, excessive and disorderly focal neuronal discharge, it follows that the types of seizures are numerous and depend on the regions in the brain from which the attacks arise. Furthermore, since the causes of seizures are manifold, the same pattern of seizures may result from a variety of cerebral lesions. Consequently, when the clinician sees a patient with seizures, he must seek answers to two questions: 1. *From what anatomic site do the seizures arise?* 2. *What is the underlying pathologic process?*

A satisfactory history is essential. This history must include a description of the onset of the major seizures or the evolution of the minor ones. This will make clear the anatomic site of origin.

Read at the meeting of the Southern Minnesota Medical Association, Hutchinson, Minnesota, September 8, 1958.

The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Analysis of the longitudinal course of the disease, including the age of the patient at onset, possible precipitating factors and the subsequent course of the illness, often suggests the underlying pathologic process. Since an attack is characteristically paroxysmal, stereotyped and brief—in other words, a discrete event—the patient himself often may give a detailed and complete description of it. However, patients must be questioned closely and required to define their terms with as much care as possible, since they often use vague and generalized terms as "dizziness," "forgetful spells" or similar phrases. The physician must be willing to listen to the patient, and a feeling of sympathy and understanding must be communicated to him. At times, the bizarre nature of the subjective experiences during an attack may make the patient reluctant to discuss them even with his physician. This is particularly true when the patient has reported these phenomena previously and has met with disregard, incredulity or contempt on the part of a physician. Yet with patience, a precise description of the attack can be obtained.

Differential Diagnosis

The differential diagnosis includes all periodic disturbances of cerebral function. The commonest of these is syncope, which is secondary to diminution of cerebral blood flow. This may occur as a simple faint, or it may be secondary to such conditions as postural hypotension or irregularity in cardiac rhythm. These attacks are more gradual in their onset and of longer duration than are episodes of true epilepsy. The patient describes the attack as beginning with a graying-out of vision. This is associated with unsteadiness and rapidly progresses to flaccid paralysis and unconsciousness; the patient usually slumps to the floor. Following the attack, the patient usually has no evidence of persistent symptoms.

Anxiety attacks are another common cause of such cerebral symptoms. The most frequent mechanism of anxiety attacks appears to be hyperventilation. The patient who has anxiety attacks frequently complains of shortness of breath associated with the fear of death, anxiety, and numbness and tingling in the fingers and about the mouth. These symptoms crescendo over a period of a few minutes and may be followed by a graying-out or even a blacking-out.

Less commonly, cerebrovascular insufficiency secondary to partial stenosis of one of the cranial arteries may cause symptoms suggestive of epileptic disorder. Although this disturbance occurs infrequently, the therapy is sufficiently different to warrant careful diagnosis. Episodes of cerebrovascular insufficiency customarily occur in patients in the older age groups. The attacks are characterized by a constellation of symptoms that can be explained by insufficiency of blood in that portion of the brain supplied by one of the major cerebral arteries. The attacks tend to persist over a longer period than the customary thirty seconds to five minutes of the epileptic seizure. Furthermore, they build up more slowly, as contrasted to the abrupt onset of the epileptic attack, and the progression of symptoms differs from that described by the epileptic patient. Each new symptom persists throughout the attack, unlike the spread in focal epileptic disorders, in which the symptoms often begin in one region only to spread to another without the initial symptom persisting throughout the attack.

Ménière's syndrome rarely may be confused with epileptic disorders. Occasionally, the attacks of vertigo occur so abruptly and are associated with so much disturbance of equilibrium that the patient may fall heavily to the floor and find it difficult to say whether or not he has lost consciousness. Attacks associated with Ménière's syndrome last longer (ten to thirty minutes or more) than do epileptic seizures and are associated with the usual auditory signs and symptoms of aural vertigo, so that the differential diagnosis in most instances can be made with considerable ease. It is important to remember that occasional epileptic seizures begin with true vertigo.

Various disturbances in metabolism create diagnostic problems; disturbances in blood urea and in the balance of blood electrolytes may lead to convulsive seizures. Changes in calcium metabolism may give rise to convulsions, and it is well to remember that patients with hypocalcemia may have convulsions that are impossible to differentiate from epileptic seizures. It is well known that hyperinsulinism may cause convulsive seizures. This, however, is relatively rare and such convulsions, when they do occur, are part of a more prolonged disturbance in cerebral function. Careful inquiry from the patient usually reveals that intake of food will abort such an attack.

Narcolepsy has been described as a variant of epilepsy. This differential diagnosis can be made easily, as the major symptom in narcolepsy is a

persistent tendency for the patient to fall asleep; he may be aroused without difficulty from this sleep.

Formerly, hysteria was important in the differential diagnosis and hysterical convulsions occurred frequently. In recent years, this diagnosis has become less common. Hysterical convulsions are characterized by their relatively long duration, by the tendency for the attack to occur in the presence of an audience, and by the frequent erotic character of the movements occurring during the seizure.

Aids in Diagnosis

The diagnosis of epilepsy depends on witnessing an epileptic seizure or obtaining an adequate history of such repeated seizures. It is frequently not possible for the physician to witness such a seizure and it is, therefore, necessary to obtain a careful history from the patient and his family in an attempt to diagnose such seizures. The epileptic seizure, as noted previously, is characterized by its brevity and the abruptness of its onset; the attack may occur at any time, although attacks have a predilection for the patient who is drowsy or who is awakening. The seizures in epilepsy, therefore, occur whether the patient is up and about or lying down; this is unlike the situation in syncopal attacks and anxiety attacks, which usually take place when the patient is erect. A relationship often is present between emotionally traumatic events and the epileptic seizure. Not infrequently, some relationship occurs between the seizure and fatigue.

In addition to the history, it is essential to obtain an adequate medical and neurologic examination. Every patient should have roentgenograms of the head, and an electroencephalogram should be obtained. Roentgenograms of the head are of particular value in the diagnosis of the cause of epileptic disorders, particularly those associated with brain tumors. The electroencephalogram is of value not only in the diagnosis but also as an aid in the classification of the epileptic disorders, and thus it may be of value in determining proper treatment. Examination of cerebrospinal fluid, air encephalography or angiography may be necessary to arrive at a definitive pathologic diagnosis. However, it is hardly necessary to reiterate that the diagnosis is not made on the basis of these laboratory tests but on the basis of an adequate history.

Once the diagnosis of epilepsy is determined, the physician may plan his strategy of treatment. This consists for the most part of three phases, namely (1) recognition, when possible, of the causes of the convulsive disorder and their eradication, (2) when eradication of the cause is not possible, instruction of the patient in how to live with his illness and (3) specific treatment for the epileptic symptoms.

Classification of Epilepsy

Classification of these epileptic disorders is essential for the proper handling of the causes, the social management and the treatment of the patient with epilepsy. We have found it most useful to classify the epileptic seizure by its clinical symptoms. Thus, epilepsy may be differentiated into grand mal, petit mal and focal seizures.

Grand Mal.—Grand mal seizures are those which are universally recognized as epileptic seizures. The attacks begin with unconsciousness and a tonic contraction of the body musculature. The eyes roll upward, the legs are extended, and the arms are flexed. The strength of the muscular contraction causes forced expiration of air from the lungs. The tongue is frequently caught between the teeth, the bladder and rectum may be emptied, and the patient falls forcefully to the ground. The tonic stage persists for a few seconds to half a minute, and the patient may become cyanotic during it. The clonic convulsive stage then develops, and the body and extremities jerk and twitch. After a few minutes, the muscles relax, the patient regains partial consciousness and his color improves. He then is somewhat confused, complains of headache and muscular pain, and usually falls into a deep sleep. Spread of the discharging cerebral focus in either petit mal or focal seizures may result in a grand mal attack.

Petit Mal.—Petit mal seizures are those attacks in childhood consisting of transient lapses of consciousness associated with spikes and waves in the electroencephalogram at a rate of three per second. These attacks are brief, lasting a few seconds; they are frequent, and may occur many times daily in the untreated patient. The attack itself consists of sudden loss of consciousness, with the patient appearing to stare into space. There may be movements about the eyelids and head and sometimes the upper extremities. The patient is mentally clear up to the onset of the seizure and appears normally alert at the end of the spell. At-

tacks of petit mal occasionally may be followed by a grand mal seizure.

Focal Seizures.—Focal seizures are those epileptic attacks whose initial clinical symptoms suggest irritation of a discrete region of the brain. These seizures at times may spread to become grand mal attacks. My associates and I have found it useful to divide all focal seizures into two broad categories. The first type we have called "splanchnopsychic" seizures. This term includes all seizures initiated with complex hallucinations, perceptual or conceptual illusions, affective states and various autonomic phenomena involving the cardiovascular system, the abdominal viscera and the respiratory system (in short, what we have described previously as "visceral seizures").[3] Such seizures may terminate in confusional states (automatisms) or generalized convulsions. In general, this category consists of what previously have been called "temporal-lobe"[4] or psychomotor seizures. We chose a behavioral term for these attacks because the so-called temporal-lobe seizures are not invariably associated with lesions in the temporal lobe, and the term "psychomotor" did not appear to stress sufficiently the frequent visceral symptoms. The remaining category, termed "sensory-motor seizures," includes all focal somatomotor seizures (jacksonian seizures), so-called supplemental motor-area seizures, adversive seizures and crude somatosensory and visuosensory seizures.

Etiology: Brain Tumors as a Cause of Epilepsy

Epilepsy is a symptom and each epileptic seizure is the result of multiple causes. Certain morbid states of the brain produce epileptic seizures as part of their characteristic symptoms. The recognition and differentiation of these specific "causes" are of importance in the proper treatment and diagnosis of epileptic disorders. As these "causes" previously have been considered in detail in another paper,[5] this discussion will be limited to brain tumors, which are a common cause of epilepsy and require definitive and separate treatment.

Ten per cent of the epileptic patients seen at the Mayo Clinic have brain tumors. The following clinical criteria suggest to the physician that further diagnostic studies to eliminate brain tumors are required in patients with epileptic seizures: 1. Onset of the seizures was between the ages of thirty and sixty years. 2. The epileptic seizures are focal in type. 3. The duration of the illness is less than five years. 4. Progressive alteration has occurred in the epileptic symptoms.

The following clinical criteria suggest that brain tumors need not be seriously considered as the cause of epileptic seizures: 1. Onset of epilepsy was before the age of twenty, and the patient has a normal skull roentgenogram. 2. The epileptic seizures are petit mal in type. 3. The duration of illness is more than ten years. 4. The epileptic symptoms have remained constant.

Diagnostic tests that are of value in determining whether a patient has a brain tumor include neurologic studies, with careful funduscopic examination, roentgenography of the head and electroencephalography. If results of these studies are normal, it is permissible to assume for the moment the absence of brain tumors in patients with seizures that began before the age of twenty. Obviously, all patients should be carefully re-evaluated periodically.

In patients who have focal seizures beginning in adult life, a structural lesion, possibly a tumor, must be assumed to exist. Failure to demonstrate such a lesion by additional studies, such as angiography and pneumoencephalography, does not preclude the existence of a tumor, and the patient must be carefully re-examined at regular intervals. In such patients, the additional findings of focal abnormalities in electroencephalograms, focal neurologic signs, or focal changes in roentgenograms of the skull increase the level of suspicion and may enable the physician to make a positive diagnosis of brain tumor in certain patients.

Orientation of the Patient

When the diagnosis of epilepsy is established and a remediable cause has not been discovered, it is customary to make a diagnosis of idiopathic epilepsy. The patient and his family will be concerned about the prognosis of the illness and the limitations it will impose on him. The patient can be told that many epileptic patients (about 50 per cent in our series)[1] have fewer than four convulsions a year and that convulsions are more common in infancy and again in adolescence. The occurrence of epileptic seizures in infants secondary to recognized illness need not be regarded as the inevitable beginning of an epileptic disorder.[6,7] In our experience, it is not uncommon for patients with epileptic disorders to have complete and apparently permanent remissions.[1] The social adjustment of most epileptic patients is good, and

many epileptic patients lead natural and normal lives in school, at home and at work.[5] In prognosticating whether a given epileptic patient will be able to make a satisfactory social adjustment, the age at onset of the disease appears to be of crucial significance.[8] If the convulsive disorder began prior to the age of ten (more specifically, if it began in the first year of life), the patient's adjustment is uniformly poor.

As already noted, the patient and his family are vitally concerned with the restrictions that his disease places on him. The commonest legal and social restriction has to do with marriage. The patient must be told that a wholly satisfactory answer cannot be given at present to the problem of heredity in epilepsy.[9,10] In our experience, heredity plays a definite although a minor role in the causation of epileptic disorders. Thus, one can suggest to the epileptic patient that his children will have a greater-than-average chance of having epilepsy and that this chance will be diminished by marrying a mate with no epileptic history in the family. The physician must advise patients who have epileptic disorders that they should not drive automobiles or engage in any other activities in which they may injure others while the epileptic attacks are uncontrolled.

Restriction should be placed on the use of alcoholic beverages, and the patient should be advised to avoid sports in which head injuries may occur.

Specific Treatment

Treatment in epilepsy is aimed at control of seizures. This is achieved through a variety of methods that may be used simultaneously or separately and are perhaps best classified as psychologic, medical, dietary and surgical. In addition to these specific methods, it is important to discuss with the patient and his family general measures of control. These include the necessity of avoiding excesses and maintaining regular hours of sleeping and eating, for it is well known that persons are particularly prone to have epileptic seizures during fatigue and relative hypoglycemia. The necessity of avoiding unusual emotional stress should be discussed. Relatives must be encouraged to avoid oversolicitous care and protection of the patient. The social handicap remains out of all proportion to the seriousness of the disease.

Psychologic Treatment.—In any illness in which the social handicap is as great as it is in epilepsy, the frequent need for specific psychotherapy to aid the patient in living with his illness is obvious. In addition, specific psychiatric treatment in patients with epilepsy may so alter the stress situation that precipitates attacks as to aid materially in the control of the seizures.

Medical Therapy.—Medication remains the principal tool of the physician in his treatment of epileptic patients. Phenobarbital, diphenylhydantoin (dilantin) sodium and trimethadione (tridione) are the principal drugs used. Drug therapy must be individualized; the proper dose is one that controls convulsions with no or minimal symptoms of toxicity. In the use of these drugs, certain general rules can be applied:[5] 1. Therapy is begun with a simple and safe drug at a minimal dose. 2. The dose of the medicament is gradually increased over a matter of weeks until the seizures are controlled or toxic symptoms appear. 3. In most instances, it is necessary to use more than one drug simultaneously. The therapeutic action of these drugs appears to be synergistic rather than cumulative. 4. Alterations in dose must be gradual and at no time must administration be discontinued suddenly. 5. Once the optimal dose is reached, it must be maintained for years. 6. The medical regimen must be tailored to fit the patient, as the pattern and timing of his attacks will be unique to him.

Treatment of most patients with grand mal or focal seizures is best started by use of diphenylhydantoin (dilantin) sodium. The initial dose is 0.1 gm. two or three times a day. The dose may be gradually increased to a total of 0.6 gm. daily in divided doses. For children less than six years of age, the initial dose is 0.032 gm. three times a day; for children six years of age or older, the initial dose is 0.1 gm. twice daily. The toxic manifestations produced by this drug are seldom serious; they include gastric discomfort and nausea, which may be obviated by taking the drug with meals or with sodium bicarbonate. Hirsutism may be an unpleasant side effect in girls and young women. Hyperplasia of the gums is a secondary effect that is reportedly retarded by massaging the gums. The only practical method of control is surgical removal of the hypertrophied gums. More serious symptoms of toxicity include nystagmus, ataxia and diplopia. These usually respond to reduction of the dose. Fever, polyarthropathy, blood dyscrasias and cutaneous eruptions are rare side

effects of dilantin therapy that necessitate discontinuance of its administration.

The convulsions in many patients with grand mal or focal seizures are best controlled by using phenobarbital and dilantin concurrently. A satisfactory dose with which to begin is 0.1 gm. of dilantin three times a day, with 0.016 gm. of phenobarbital given at the same time. The dose of phenobarbital then may be gradually increased to tolerance, beginning with a nightly dose of 0.032 to 0.1 gm. An effective dose for many adults is 0.1 gm. of dilantin with 0.032 gm. of phenobarbital given three or four times a day. These drugs are now available combined in varying doses in one capsule.

Use of trimethadione (tridione) is a treatment of choice in patients with petit mal. Its administration may be started in doses of 0.3 gm. daily, with gradual increases in adults and adolescents to total doses of 2.7 gm. daily in divided doses. Patients frequently complain of photophobia and hemeralopia, which may disappear with continued use. Toxic dermatitis may occur, but it also responds to withdrawal of the drug. In children, the dose should be proportionate to weight. In most patients, it is wise to use in addition phenobarbital or dilantin to avoid grand mal attacks. Unfortunately, serious complications such as aplastic anemia, agranulocytosis and nephrosis have been reported; their appearance necessitates discontinuance of administration of the drug. Because of these complications, patients receiving tridione must be carefully observed, and monthly urinalysis and routine blood studies are indicated.

Status epilepticus or recurrent seizures are best controlled by the intravenous injection of 0.4 to 0.8 gm. of phenobarbital sodium or 0.5 to 1 gm. of amobarbital sodium in distilled water. In children, half this amount is required.

Many other drugs have been reported as efficacious for epilepsy in recent years.[11] However, none of these have proved as satisfactory or safe as phenobarbital, dilantin and tridione. When these three drugs are ineffective, one may consider the use of one of the newer drugs, recognizing that the toxicity of these drugs is not as yet well delineated.

Discontinuing Therapy.—Prior to withdrawal of medication, the patient should understand and be willing to assume the responsibility for an increased risk of convulsive seizures. If the patient still wishes to consider withdrawal, he should be advised to do it slowly over an interval of several months. In addition, it would appear wise for the patient not to discontinue therapy during adolescence or any other period of undue stress.

Dietary Therapy.—In the past, a ketogenic diet has proved successful in the treatment of convulsive disorders.[12] However, the use of drugs is usually simpler than maintaining a patient on such an unpalatable diet for any length of time. The ketogenic diet now appears to have its main usefulness in children whose condition cannot be controlled adequately with drugs.

Surgical Therapy.—Surgical intervention has been advocated as the treatment of choice for patients who are handicapped by focal seizures that cannot be controlled medically. In such patients, surgical extirpation of the cerebral focus from which the seizures arise may be considered. This form of treatment is still in the process of final evaluation.

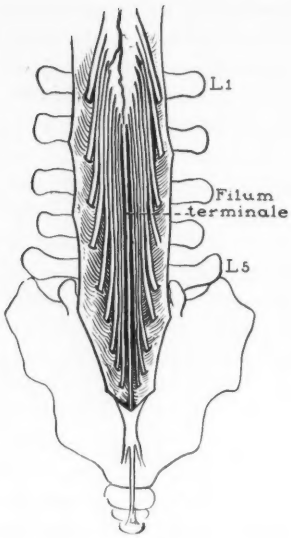

Fig. 1. Anatomic relationship of the filum terminale to the conus medullaris and the lumbar and sacral vertebrae.

The So-called Tight Filum Terminale Syndrome

ALFRED UIHLEIN, M.D.
Rochester, Minnesota

From the Section of Neurologic Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.

• *"It's Tight Like That" is the theme of a classic piece of jazz that can be applied on occasions to the filum terminale, which represents the caudad portion of the spinal cord that normally becomes a fibrous strand. If this strand is not long enough, it puts tension on the conus medullaris and roots of the cauda equina. The author illustrates the relatively specific neurologic disorder associated with a tight filum terminale.*

THE so-called filum terminale syndrome unfortunately has become a loosely applied term to designate any number of clinical entities whereas in reality the syndrone does represent a circumspect clinical picture which can be recognized.[1,2] The filum terminale frequently has remnants of ependymal cells which undergo tumorous changes from which lesions arise. However, inadequate differentiation of the filum during the period of body growth, with lengthening of the filum as the vertebral column descends, can exert sufficient traction on the roots of the cauda equina and the conus medullaris to produce a demonstrable neurologic disorder.

A brief anatomic review of the filum terminale will help define the relationship of this structure to the syndrome which bears its name. The filum represents that portion of the spinal cord, caudad to the second coccygeal segment, which finally becomes converted into a fibrous strand. [3,4] This strand elongates in adaptation to the ascending displacement of the spinal cord. The caudal tip of the dural sac maintains its relationship to the

vertebrae rather than to the spinal cord, and remains attached to the filum terminale in the sacral region at a more or less fixed point.[5] The terminal end of the filum is fixed to the coccygeal ligament, of the lumbosacral or sacral coccygeal area sometimes is encountered. There may be skeletal dysraphia or even diastematomyelia. The development of progressive spastic paralysis while patients are

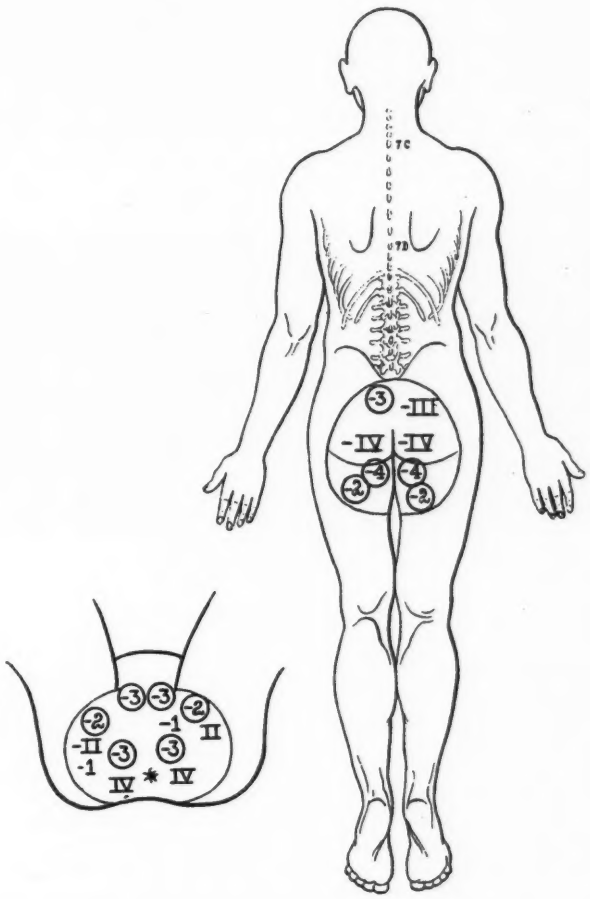

Fig. 2. Sensory changes as noted in Case 1.

while the more cephalic portion persists as the ventriculus terminalis[6] of the conus medullaris (Fig. 1). Ordinarily, the filum terminale is not under tension and merges imperceptibly with the conus medullaris.

The symptoms of progressive spastic paralysis of the lower extremities, with or without urinary difficulties in the adolescent patient, should suggest the possibility of a tight filum terminale. Spina bifida occulta or dimpling of the skin in the region under observation for other conditions should arouse suspicion of the syndrome.[1]

Two Illustrative Cases

Two patients who presented the symptoms of, and in whom the observations pointed to, an unexplained progressive paraparesis of the lower extremities suggested the possibility of a tight filum terminale, and the clinical findings in the cases were of sufficient interest to warrant this report.

Case 1.—In 1945 a woman, aged thirty-three, noted on one or two occasions loss of a few drops of urine while she was up and about. She had no additional difficulty of this kind until 1947, when she consulted her local physician because of recurrent pains in the right lower abdominal quadrant. Appendectomy was performed, and cysts in both ovaries were punctured. Between 1951 and 1954 the patient experienced frequent bouts of urinary difficulty consisting of incontinence, urgency and dribbling. She was forced to wear a perineal pad most of the time. She also began to notice alteration of her bowel habits, and began to take laxative agents and enemas. In 1955 she first noted relaxation of the anal sphincter and soiling of her undergarments by fecal material. For several years before we saw her, fecal incontinence had become progressive. In 1956 she saw her local physician because of the foregoing symptoms and because she was also noticing some pain in the lower part of the back. This pain extended into the right leg and as far as the popliteal region and the foot. It was not lancinating nor did it seem similar to the pain of true sciatica. Weakness and heaviness of the right leg and foot ensued. All these symptoms had gradually progressed. More recently, coughing, sneezing and straining, as well as lifting objects or jarring or riding in a car, aggravated the pain in the back as well as that in the right leg. When the urinary bladder was examined for residual urine, retention of between 200 and 300 cc. of urine was found.

In June 1956, the patient was admitted to a hospital near her home, where a myelogram (pantopaque) was made. Results were reported as normal, and the value for protein in the cerebrospinal fluid also was found to be within normal limits. In April and May 1957, the patient was re-admitted to the same hospital because of an infection of the urinary tract, and at this time 1400 cc. of residual urine was found, associated with definite overflow incontinence. Another pantopaque myelogram was made and was reported as disclosing nothing abnormal.

The patient was first seen by us in March 1958. Results of a general medical examination seemed to be essentially normal. However, at neurologic examination, the patient was found to have definite Babinski reflexes bilaterally and weakness of the lower extremities, greater on the right than on the left. A definite sensory loss to all modalities was noted in the sacral rootlets, with sensitivity to touch, pain and temperature reduced as indicated in Figure 2.

On the basis of our examination we obtained the impression that the patient probably had an intramedullary tumor in or near the conus medullaris or some rare type of sacral syringomyelia. It is of interest to note that the sensations of pain and temperature were much more severely affected, while that of touch was only slightly diminished. A pantopaque myelogram was made, but it disclosed no abnormality. The value for total proteins in the cerebrospinal fluid was 10 mg. per 100 cc. A roentgenogram of the lumbar area of the spinal column did not reveal any abnormality, and no other congenital defect of the skeletal system was found. Examination of the skin in the sacral area disclosed a small dimple near the first sacral vertebra.

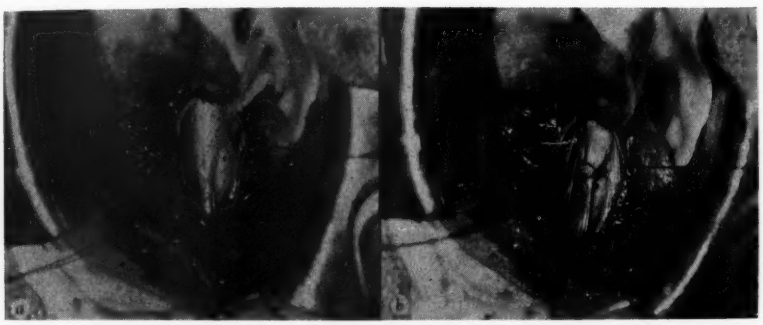

Fig. 3. *(a* and *b)* Surgical findings in Case 1.

Because of the progression of the patient's symptoms, an exploratory operation was advised. The patient accepted this counsel. On April 8, 1958, with the aid of general anesthesia, the usual level of the conus medullaris was explored in the region of the first lumbar vertebra. Minimal bilateral laminectomy was carried out. When the dura was opened, it was obvious that the conus medullaris was not located at this level. Exploration was then carried out between the third and fourth lumbar vertebrae, and again the spinal cord was observed. No evidence of a cauda equina could be found.

Laminectomy was then carried out at the fifth lumbar and first sacral levels, where the conus medullaris was found to be attached to the dura at the level of the first sacral vertebra. The conus medullaris had undergone degenerative changes and looked somewhat like a lipoma (Fig. 3*a*). Anterior to this attenuated conus was a very tense fibrous band that resembled the usual filum terminale.

First, the attachment of the conus to the dura was divided between black silk sutures (Fig. 3*b*), and then the tight filum likewise was divided. The lower elements of the conus as well as the resected filum receded upward about 1.5 cm. after the structures were cut.

The pathologist reported that the tissue submitted from the area of the conus represented fatty cells and nerve fibrils. A rubber catheter was passed rostrally for a distance of at least 8 inches and no obstruction was encountered. The catheter also was passed distally, but it would descend only for about 1.5 cm. before the end of the dural sac was reached. The operation was then terminated.

The convalescence of the patient was uneventful. It was her impression that the area of objective sensory loss was not so great at the time of her dismissal. However, neurologic examination indicated the degree of sensory loss to be about the same. The patient herself, however, felt that her legs were less spastic, that her back was stronger and that the preoperative pain and heaviness of the right lower extremity had been relieved. She no longer had any difficulty with retention of urine and, by careful around-the-clock regulation of elimination, she had no difficulty with fecal incontinence. The day before her discharge the output of urine was 425 cc., with only 30 cc. residual.

This case shows that even though a tight filum terminale was present, a congenital abnormality of the lower end of the conus medullaris also was associated. Undoubtedly, traction played a major role here and produced the progressive deterioration that has been described. We anticipate a satisfactory recovery, although much of the neurologic deficit will persist.

Case 2.—A woman, aged thirty-four, came to the Mayo Clinic complaining chiefly of deformity of the left foot, with twitching of the left leg, that had been present for ten years. The patient said that as long as she could remember she had had a deformed left foot, and that she was supposed to have had poliomyelitis at the age of eleven months. The patient was able to walk and to stand by the time children normally are able to do so. A younger half-brother of the patient had cerebral palsy with athetosis. The patient had left school in the twelfth grade because she was sensitive to the curiosity of others in respect to her slight limp. She remarked that she was still conscious of the limp and that she desisted from going about in public because of it. She had four children and was able to care for her own house as well as her children without any difficulty. She reported that if she walked two or three blocks the left ankle had a tendency to become weak and the foot to invert. She never had fallen, but the weakness produced considerable disability. She never had experienced pain, but she had noticed involuntary jerking movements in various places in the calf and leg on the left side.

Results of a general physical examination of this patient were essentially normal, except for the lower extremities. The right foot was larger than the left, and the left foot was deformed, with a talipes cavus type of alteration. There also was an anomaly of the proximal phalanx of the fifth toe of the left foot. A tarsocalcaneal coalition on the left, with the talipes cavus deformity of the foot, was noted, and there was some lateral separation of the right ankle joint, with eversion deformity.

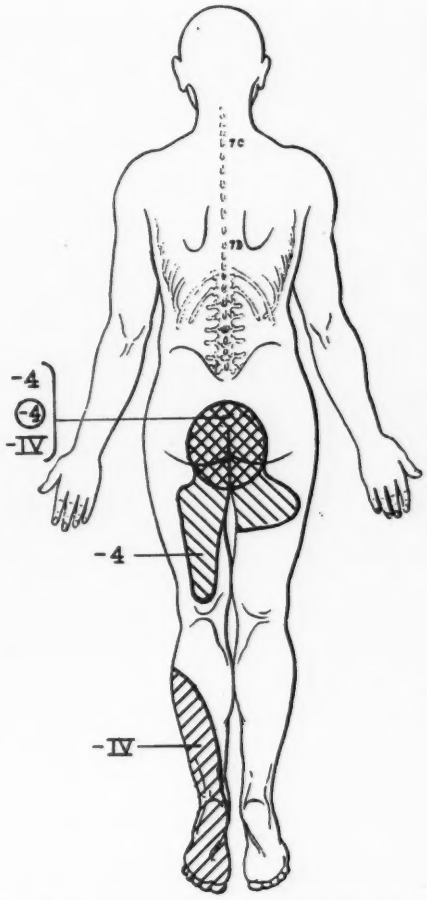

Fig. 4. Sensory changes noted in Case 2.

At neurologic examination, ankle jerks were absent bilaterally, whereas the remaining reflexes were normal. The tone of the anal sphincters was reduced, minus 2 to 3 on the basis of 1 to 4, and there was definite weakness in dorsiflexion of the toes, especially on the left. There was weakness in the adductors as well as the abductors on the left, and sensory loss to pinprick and temperature was noted, as indicated in Figure 4. A roentgenogram of the lumbar area of the spinal column disclosed no abnormality. It was not felt by the orthopedic surgeon who saw this patient in consultation that any specific treatment was indicated. A pantopaque myelogram was made on May 21, 1958. This showed the common dural sac lying posteriorly against the bony wall of the spinal canal, suggesting a tight filum terminale (Fig. 5). The

conus medullaris seemed to lie in a normal position. Otherwise the myelogram gave no indication of abnormalities. The value for total proteins in the cerebrospinal fluid was 25 mg. per 100 cc. An electromyogram also was made; it revealed damage to anterior-horn cells

Fig. 5. Contrast myelography of the lumbar portion of the spinal canal in Case 2, demonstrating the dural sac being pulled away from the anterior portion of the spinal canal.

at the level of the lumbar fifth and sacral first vertebrae.

At operation on May 21, 1958, bilateral laminectomy was carried out at the level of the fifth lumbar and first sacral vertebrae. Intradural exploration did not reveal any evidence of a tight filum terminale or an abnormal lesion of the cauda equina. Exploration was then carried out between the first and second lumbar vertebral levels, and again there was no evidence of a tight filum terminale. The conus medullaris appeared to be in a normal position; it was not malformed or surrounded by or comprised of tumor tissue. A rubber catheter was passed distally as well as rostrally, and no obstruction was encountered.

Convalescence of the patient was uneventful. It was felt that the patient probably had a congenital anomaly of the lower extremity on the left, and it might well be that as a child she had had poliomyelitis which resulted in the damage to the anterior-horn cells as indicated by the electromyogram. This case is of interest in that the same objective sensory changes were noted in this patient as were seen in the first case presented herein, but even so, a true tight filum terminale or abnormality of the conus medullaris could not be identified. However, the patient did present sufficient evidence to warrant surgical exploration to determine the presence or absence of a pathologic process.

Summary

This presentation has two objectives: first, to clarify the true situation in what usually is referred to as the "filum terminale" or "tight filum syndrome"; and second, to present some of the more prominent clinical features that should attract the attention of the examining physician when he is confronted by the problem of progressive paraparesis in an adolescent person in whom there is no other adequate explanation for the findings. It is postulated that the continued traction exerted by a filum terminale that is tight will produce degenerative changes in the lower part of the spinal cord. Hence, it is believed in such instances that early surgical intervention might prevent irreparable, progressive neurologic changes by determining the presence or absence of an abnormally low-lying conus medullaris of the spinal cord or a tight filum terminale or both. Roentgenograms of the thoracic and lumbar vertebrae, as well as contrast myelography, should be included in the measures employed in these interesting clinical problems. Whether the presence of a tight filum terminale is responsible for disorders of the central nervous system at a level higher than the conus medullaris is open to speculation.

Many persons have thoughts about death even though they are unlikely to discuss them in casual conversation. These feelings may be brought into sharp focus during illness or old age. The physician is in a key position to discuss the problem of death with his patient or listen with wisdom to the patient's expressions. The author reviews some interesting findings on this generally neglected subject.

Attitudes Toward Death Among the Aged

Their Significance in the Practice of Geriatric Medicine

WENDELL M. SWENSON, Ph.D.

Mankato, Minnesota

Chairman and Associate Professor, Department of Psychology, Gustavus Adolphus College, St. Peter, Minnesota.

WE, IN AMERICA, proudly label ourselves a youthful nation; but within our structure there exists an interesting and somewhat paradoxical fact—we are a rapidly aging population. Man's life span continues to increase in a spiral fashion. At the time of Christ, human life expectancy was said to be about twenty years. During the American Colonial period that expectancy had increased to thirty-five years. In 1850 man could expect to live about forty years, and now we hold hopes for a seventy-year life span. Today about 9 per cent of our U. S. population is over the age of sixty-five. This problem is obviously significant from the point of view of the medical sciences—especially when one discovers that 72 per cent of individuals over age sixty-five report at least one chronic illness.

The gerontic population with all its complexity and variability does have one common experience to be anticipated—death. The temporal aspect of life is perhaps one of the most empirically tested scientific facts known to man. A half century ago death came earlier in the human race, and the death process was experienced mostly in a sudden or traumatic manner by individuals gainfully employed or otherwise functioning well in society. Now, in the middle of the twentieth century, death commonly comes to individuals who have long since been retired from active social participation and are physically or psychologically incapacitated—presumably giving them considerable time to contemplate death as an impending experience. This development poses a number of rather stimulating questions—What are some of the characteristics of this "death contemplation"? Does it exist in all individuals? If so, can it be measured? Do millions of gerontic individuals all have the same ideas concerning death? In what manner do they deal with the problem? As they grow less and less productive in our society, do they have less and less a desire to live?

The medical sciences seem to have a singular goal or aim which cuts across lines of both research and clinical medicine—to preserve human life as long as possible. Hospitals of many types are now devoting wards or even buildings to the collocation of elderly people who, by present standards, have no useful place in our culture, but still do not die.

This paper was developed, in part, from a doctoral dissertation presented to the faculty of the University of Minnesota, 1958, and read at the annual meeting of the Southern Minnesota Medical Association, Hutchinson, Minnesota, September 8, 1958.

As the general practitioner begins to spend more time with the care and treatment of the geriatric patient, he no doubt becomes more sensitized to this problem area. A number of queries here would seem pertinent. How much does the geriatric patient think about death, if he thinks of it at all? Does he tend to fear the death experience, look forward to it, or repress it completely from his conscious thought? What role should the family physician play in discussing the possibilities of death with either the patient or his relatives? Should the physician assume that his geriatric patient is suffering from a relatively intractable fear of the death experience or can he conclude that elderly individuals have resolved the problem of death? Just how much is anxiety of death related to either vague or well-defined psychosomatic complaints of the patient?

In an attempt to answer these and many other related questions, this investigator recently set out to measure the attitudes about death of a large number of gerontic individuals.

The Literature

Little medical research has been done in this area to date. Eissler[1] has evaluated the dying patient from a psychiatric point of view. Warbasse[2] feels that the medical profession has a particular responsibility in teaching old people how to die, and it is his (the physician's) duty to make the patient free of the discomforts surrounding this experience. Williamson,[3] in writing about the fears of older people, postulates that our present-day society with its cares, anxieties, and torments resulting from an emphasis on a fear of the unknown, have caused a distinct increase in the fear of death. He takes a highly religious stand regarding the problem in stating that if man has a degree of certainty about life-after-death he will have no cause for fear of death.

Psychologists have had little more success in attempting to spell out the death concept in older people. Klopfer[4] found that the more active aged individuals had less fear of death than did the inactive ones. Feifel[5] interviewed forty white men, veterans of World War I at a Veterans Administration Domiciliary, and found his subjects either visualize death as the dissolution of bodily life and the doorway to a new life, or to view the experience with "philosophical resignation" or as "the end." None of these studies, or other similar ones, seems to give any explicit answers to the questions previously posed by this investigation.

Method

The present investigation described here involves an attempt to obtain an objective measure of the death attitudes of a reasonably good cross-section of aged individuals. A brief description of the procedure follows.

1. Thirty-four individuals, over age fifty, were asked to place their immediate thoughts concerning death into the form of a brief essay. This material was methodically screened for descriptive statements about death. Thirty-five of these descriptive statements evolved from the screening process and were used to measure the death attitudes in the larger group to be studied. The descriptive statements in this thirty-five-item check list fell rather clearly into three major categories describing death: first, a group of *positive or forward-looking* attitudes exemplified by such statements as "it will be wonderful," "promise of a new and better life," and "all troubles will be over"; second, an *evasive* attitude toward death exemplified by such statements as "don't think about it," "have nothing to do with the subject," and "feel fine and no reason to think about it"; and third, a *fearful* attitude toward death exemplified by such statements as "the end of everything," "terror overcomes me," and "dread the thought of it."

2. This Death Attitude Check List was presented to more than 200 individuals, all over the age of sixty years. The subjects were obtained from three separate sources: (a) homes for the aged, (b) so-called golden age clubs, and (c) a number of industries and companies employing individuals over the age of sixty years.

3. On the basis of their responses to the Check List the subjects were divided into three rather well-defined groups—those looking forward to death positively, those avoiding any thought of death, and those fearing the death experience.

4. These derived groups were analyzed to determine the relationship, if any, between attitude toward death and certain measurable physical and social characteristic. One general assumption was made—the closer the proximity of death through age, illness, loss of relatives, and so forth, the more acceptant or positive would be the indi-

vidual's death attitude, that is, the more he would welcome or look forward to death. Some specific predictions are implicit in this general statement.

Age.—The older the individual, the more positive and acceptant will be his attitude toward death.

Physical Condition.—The poorer the individual's physical condition the more positive will be his attitude toward death.

Home Living Conditions.—The more solitary man's home situation and the less his financial security, the more he will look forward to death.

Religiosity.—The more fundamental one's religion and the greater his religious activity, the more positively he will look forward to death.

Results

Tabulation of the results revealed the following general breakdown of the subjects with regard to their death attitudes.

1. Almost half the group (45 per cent) admitted to a positive or forward-looking attitude toward death.

2. Also almost half the group (44 per cent) were distinctly evasive in their attitudes, indicating they preferred not to think about death.

3. Only a small and relatively insignificant number (10 per cent) admitted to having any fear of the death experience.

Some specific predictions were made with regard to the relationship between death attitudes and age, physical condition, home living conditions, and religiosity. Using accepted statistical techniques, the significance of these relationships was determined. A brief résumé of the results follow.

By far the most significant relationship was found in the individuals' religious beliefs and activities and their death attitude. Persons engaged in frequent religious activity or demonstrating a fundamentalist type of religion evidenced a very positive or forward-looking death attitude, whereas those with little religious activity or interest either evaded reference to death or feared it.

The second most significant relationship occurred with regard to the subjects' living conditions and their death attitudes. Individuals residing in homes for the aged commonly looked positively toward the death experience. Individuals living with spouse or alone tended to evade the issue of death. There was some evidence to suggest that a fear of death was found most commonly in those individuals who lived alone outside a rest home.

The relationship between death attitude and level of education and condition of health was of much less intensity and showed only suggestive significance. The more educated subjects (college trained) either looked forward positively toward death or feared it, whereas the less educated (grade school) were evasive and preferred not to think of it. In other words, the educated individual faced the problem of death—either looking forward to it or fearing it, and the less educated individual avoided considering it. With regard to the relationship of general health to death attitude, the evidence suggested that those individuals admitting to good health were actively evasive in the consideration of death, whereas, those indicating poor health tended to have a positive or forward-looking attitude.

No relationship could be demonstrated between type of death attitude and sex, age, occupational status, or source of income.

Discussion and Implications

Let us now re-examine the essential results of the study with a consideration of more practical conclusions to be drawn from the data—especially with respect to their possible application to the practice of geriatric medicine.

1. The first and perhaps most significant result of this investigation is that it has demonstrated that death attitudes can be objectively measured with a structured psychometric device. It now seems neither necessary nor scientifically practical to attempt to determine a person's attitude toward death by devious or indirect methods—through the "tapping of the unconscious." It is apparent that to obtain a "death attitude" from an individual, one need merely ask some direct questions about it.

2. Fear of death tends to be relatively nonexistent in the conscious thought of the aged. At least the average gerontic individual does not consciously admit a fear of death. He either looks forward to it or evades any reference to it. For the physician treating the geriatric patient, this problem of conscious fear of death, then, need not necessarily be considered as serious. It is reasonable to assume that the average geriatric patient has either developed a philosophy of life

which makes death a fairly pleasant positive experience or he has repressed beneath the level of consciousness any concern about it.

3. Religion and religious activity apparently play a very intrinsic role in the gerontic individual's concept of death. Positive or forward-looking death attitudes were found most frequently in the actively religious group. The obvious conclusion here is that the person of firm Christian beliefs or convictions has a more positive religious orientation and therefore looks forward to the experience of death. This facet of the problem seems pertinent in the practice of geriatric medicine—a knowledge of an individual's religious convictions and habits may well give the physician distinct clues as to the amount of conscious fear of death existing in his patient.

4. Individuals living in homes for the aged look forward positively to death much more than do certain non-institutionalized gerontic people, whereas those living alone tend to fear the prospect of death. It is apparent that living a solitary existence in old age is associated with a more negative or fearful concept of death. Fear of death, then, seems to be related to solitude. One can infer from these results that older individuals living under relatively normal circumstances—that is, with husband, wife, or other relative, do not concern themselves with the process of death and therefore neither look forward to it nor fear it. Avoidance of death contemplation seems to be associated with the more normal type of social environment.

5. The possible implications of the slight relationship between educational level and death attitudes are of interest. As has been indicated, the individual with relatively little education seems to give less concern to the problem of death (perhaps not understanding its complexity), and, therefore, wants no part of discussing it. The educated person, having confronted the problem directly, has either resolved it through some sort of religious or philosophic adjustment or has become frustrated in dealing with the concept and has yet met with no solution—thereby fearing the death experience.

6. One final observation with regard to the discovery of positive relationships. It is apparent from the data that individuals in poor health tend to actually look forward to death more than fear it. It seems reasonable to infer, then, that the physician treating the terminal geriatric patient need not assume any predominant fears in his patient, but rather expect the existence of rather well-organized, positive, forward-looking attitudes toward death. The fact that individuals in good health avoid contemplation of death no doubt reflects the obvious fact that they have simply not yet found the immediate necessity or perusing it.

7. The negative results of this study are also of some significance. Chronologic age, itself, seems to have no value in predicting thoughts concerning death, and there is no evidence of a sex difference in contemplation of death.

Conclusions

It is hoped that some of the conclusions of this study may be of practical value in the consideration of the total personality of the geriatric patient as he is seen and treated in a medical setting. Death is truly a universal experience contemplated by all men. Evaluation of this contemplation would seem to be an intriguing subject of consideration not only for the theologian, philosopher, and psychologist, but also for the physician. For who, more than the practicing physician, deals with individuals, old or young, who are so concretely aware of the possibility of termination of life? Although not explicit in the objective results outlined in this research, I am convinced that individual man considers, ponders, and contemplates this most significant experience of his life much more intensely than is generally believed. The problem is a vast and multivariate one which should demand the careful consideration of many disciplines.

Leonardo da Vinci is claimed to have stated: "While I thought that I was learning how to live, I have been learning how to die."

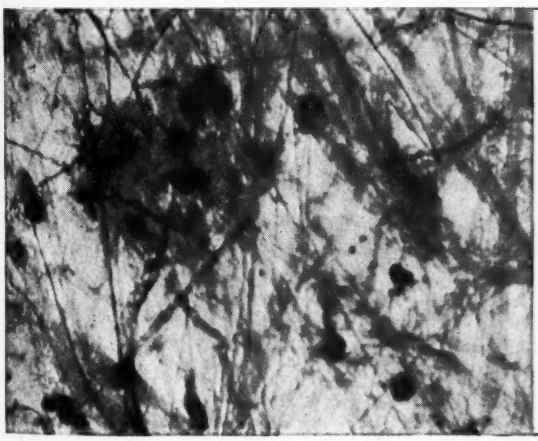
NOW—YOU CAN GET THE
UNSURPASSED ADVANTAGES
OF ARISTOCORT
IN SALICYLATE
COMBINATION

Aristo



Aristogesic combines the *anti-inflammatory* effects of Aristocort® Triamcinolone with the *analgesic* action of a most potent salicylate. This means that the dosage of each is *substantially lower* than that ordinarily required for each agent alone. With Aristogesic the physician has exceptionally wide latitude in adjusting the dosage to the lowest effective level.

The possibility of gastric distress from either salicylamide or corticosteroid is minimized because of lower dosage required. This is further reduced by the buffer action of aluminum hydroxide. And the ascorbic acid helps meet the increased need for this vitamin in stress conditions. Because of the low dosage, side effects with Aristogesic have been relatively infrequent and minor in nature. However, more serious side effects have traditionally been observed on all corticosteroid therapy. Patients on long-term Aristogesic therapy should, therefore, be observed carefully.

ogesic*

Steroid—Analgesic Compound LEDERLE

for relief of *chronic*—but *less severe* pain of rheumatic origin

Indications: Mild cases of rheumatoid arthritis, tenosynovitis, synovitis, bursitis, mild spondylitis, myositis, fibrositis, neuritis and certain muscular strains.

Dosage: Average initial dosage: 2 capsules 3 or 4 times daily. Maintenance dosage to be adjusted according to response.

Each Aristogesic Capsule contains:

ARISTOCORT® Triamcinolone . . . . . 0.5 mg.
Salicylamide . . . . . 325 mg.
Aluminum Hydroxide . . 75 mg.
Ascorbic Acid . . . . . 20 mg.

Supply: Bottles of 100.

Left-sided Pneumatosis Coli

Report of a rare condition now becoming more generally recognized.

CHARLES A. NEUMEISTER, M.D.
Minneapolis, Minnesota

Assistant Clinical Professor of Surgery, Division of Proctology, University of Minnesota, Minneapolis, Minnesota.

PNEUMATOSIS COLI is an entity which is being recognized with increasing frequency during the past few years. This is, in all probability, due to the increasing number of sigmoidoscopic examinations being done.

As early as 1952 Koss[1] reviewed the literature and found thirteen of 213 reported cases of intestinal pneumatosis where the cysts were limited to the large bowel. Since that time, increasing numbers of cases have been reported and one would conclude that this entity is more common than was at first thought. The entity can be recognized by sigmoidoscopic examination and major surgery avoided in most cases. Pneumatosis should be suspected whenever multiple sessile polypoid-appearing areas with pale tense colonic mucosa are visualized on proctoscopic examination. Biopsy will confirm the diagnosis.

Littman[2] gives a very excellent description of the sigmoidoscopic appearance of this entity. He describes the proctoscopic picture as "numerous cyst-like globular masses protruding into the lumen in a scalloping manner, partially occluding it." The mucosa covering the cysts is pale, tense and seems fixed. He also states that after biopsy the wound appears honeycombed, and bleeding, if any, is minimal. In Littman's cases a frothy secretion was present in both instances; however, I personally have observed this in numerous patients without pneumatosis and would be inclined to believe this was not a significant finding.

Presented at the meeting of the Southern Minnesota Medical Association, Lake City, Minnesota, September 9, 1957.

Pathology

It has been stated that the pathologic picture is best explained by the theory that gas distending the lymphatics with blockage of the lymphatics causes the cystic distention in the submucous and subserous layers of the bowel. In the early stages the cysts are lined by endothelial cells which later coalesce to cause multinucleated giant cells. Castleman[3] suggests that the gas in the lymphatics causes an irritation and secondary inflammatory reaction is seen around the cysts; this, in turn, causes blockage of the lymphatics with cyst formation. The composition of the gas in the cysts has apparently never been determined. The inflammatory reaction surrounding the cysts varies from the acute type with leukocytic infiltration to granulomatous changes with epithelioid cells and giant cells of the multinucleated type. In the final stages, the lining cells are sloughed off and cystic spaces without any lining are the end stage.

Etiology

Several theories as to the etiology of this disease have been proposed. The three most popular are the chemical, mechanical and nutritional. Of these three, the theory which seems to be on the firmest ground experimentally is the nutritional theory. Marshak et al[4] proposed that trauma incidental to sigmoidoscopic examination was one of the etiologic factors in this syndrome. In view of the thousands of sigmoidscopic examinations done and the mechanical trauma of hard stools, one would be inclined to discount this as an etiologic factor stince pneumatosis of the colon is relatively a rare condition.

The chemical theory of abnormal diffusion of

gasses through the colonic mucosa with subsequent cyst formation seems to defy some of the more basic laws of physics and chemistry so this, too, I believe is not a good explanation.

In support of the theory of a nutritional deficiency, it has long been observed that intestinal pneumatosis was a condition frequently observed by butchers in swine. In 1936 Biester et al[5] reported on the experimental production of these lesions in swine. Further studies by these same authors[6] have shown that a diet consisting of 78 per cent polished rice, 20 per cent skim milk and 2 per cent minerals produced pneumatosis in 100 per cent of hogs fed on this diet. The addition of 5 per cent bakers' yeast protected four of five pigs fed on this diet. A diet consisting of 50 per cent skim milk also afforded protection against emphysema. No cases of emphysema were observed if unpolished rice or whole grains were used in the diet.

From this evidence one would feel that the B-complex vitamins contained the anti-emphysema factor but the authors conclude it is some other factor since none of the animals which developed emphysema showed other signs of vitamin B deficiency. To further support their argument, they have shown that the animals' diet must contain enough B-complex vitamins to produce a weight gain of 0.5 pound per day in order to develop emphysema.

Thus, the exact etiology of pneumatosis coli in the human is completely unknown.

Symptomatology

The symptomatology is vague and it is possible that many cases of pneumatosis go unrecognized. Littman's[2] cases had vague abdominal discomfort, constipation and diarrhea, complaints which often do not cause patients to seek medical advice. The patient whose case is being reported here complained of only vague abdominal discomfort with occasional cramps and no irregularity of stool. There was no bleeding as was reported in one of Littman's cases.

Case Report

A white woman, aged forty-nine, was first seen with vague complaints of abdominal distress of an aching type. She had been seen by her family physician who noted what appeared to be multiple polypoid lesions beginning at the 8 cm. level on sigmoidoscopic examination. Her past history was non-contributory. The patient had always enjoyed good health. Laparotomy for an ovarian cyst was the only surgery reported. Routine laboratory studies were within normal limits. Barium enema studies revealed multiple polyps throughout the descending and sigmoid colon. At laparotomy and colotomy, the diagnosis of left-sided pneumatosis was definitely established. No polyps were found. Two months after the surgical diagnosis, sigmoidoscopic examination revealed almost complete disappearance of the intramural cysts. The patient was asymptomatic. No specific treatment had been undertaken other than observation.

Summary

Intestinal pneumatosis is a syndrome of unknown etiology which has been reported with increasing frequency in the past few years. Pneumatosis limited to the colon is relatively a rare condition. Of the theories proposed as to its etiology, the nutritional deficiency theory is the only one supported by experimental evidence. The syndrome is self-limited and requires no specific treatment unless complications supervene.

A case of left-sided pneumatosis coli is presented and some of the pertinent literature on this syndrome is reviewed.

Conclusions

1. The diagnosis of left-sided pneumatosis coli can be made by sigmoidoscopic examination.
2. Biopsy of the lesions through the sigmoidoscope has been done[2] and apparently is a safe procedure.
3. Once the diagnosis of pneumatosis is made, the treatment is expectant and one can expect spontaneous remission.
4. The etiology of this syndrome is very obscure and experimental evidence in animals points to a dietary deficiency and/or toxicity as the causative factor.

Varicose Veins During Pregnancy

● *What should the physician advise when faced with the common problem of the pregnant woman with varicosities? Although surgical extirpation of the offending veins is the most efficient treatment, it should be postponed until some time after delivery. The author outlines conservative measures that may be used during pregnancy.*

KARL A. LOFGREN, M.D.
Rochester, Minnesota

From the Section of Peripheral Vein Surgery, Mayo Clinic and Mayo Foundation, Rochester, Minnesota.
The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

VARICOSE VEINS during pregnancy are very common, but their management is controversial. Some authors recommend surgical treatment (ligation and injection or stripping) during pregnancy, while others advise injections with sclerosing solutions, and still others favor conservative, nonsurgical management with elastic support. The purpose of this paper is to discuss briefly the handling of this problem as practiced at the Mayo Clinic.

The development of varicose veins during pregnancy is a well-recognized occurrence. Pregnancy imposes a definite strain on the veins of the lower extremity which often results in varicosis in a susceptible individual. Although no reliable figures on incidence exist, probably one out of five pregnant patients has varicose veins. They usually do not persist after the first pregnancy, but they almost invariably have become well established by the third pregnancy.

Certain physiologic changes during pregnancy directly affect the venous function of the lower extremity and must be appreciated for a proper understanding of this condition. The total blood volume increases during pregnancy. The blood volume and flow in the pelvis are markedly increased as the uterus grows and the placenta and its numerous arteriovenous communications develop. The growing uterus causes mechanical pressure on the iliac veins and thus gives rise to increased venous pressure in the lower extremities, as was shown by Burwell.[1] McLennan[2] made similar observations. They found that this increased pressure in the femoral veins returned promptly to normal after delivery. Veal and Hussey[3] noted increased pressure in the popliteal vein during exercise in pregnant patients. The venous flow from foot to groin slows down during pregnancy, as was demonstrated by Wright and coworkers[4] in a study using radioactive sodium. The increased blood flow in the pelvis secondarily impairs the return flow through the femoral veins and thus also contributes to the venous congestion in the lower limbs. The role of hormones in causing vasodilatation during pregnancy may be another factor, though not clear or proved. As a result of these physiologic changes associated with pregnancy, a state of diffuse dilatation and distention of all superficial veins in the lower extremity exists during pregnancy, but this state usually terminates at delivery.

In a patient with inherent susceptibility for varicosis, the distended veins may not return to normal size after delivery but instead may remain

Read at the meeting of the Southern Minnesota Medical Association, Hutchinson, Minnesota, September 8, 1958.

permanently dilated and incompetent. With each succeeding pregnancy the breakdown becomes more and more extensive, involving more and more superficial veins. During pregnancy, not only are the greater or lesser saphenous systems involved, but frequently also the venous networks in the vulvar and perineal regions are affected. In early pregnancy, scattered clusters of bluish venules, so-called angiectids, are often seen distributed over the thighs and legs. Some authors have attributed them to the influence of hormones, though it seems more likely that they are due to the over-all venous congestion in the lower limbs.

Management

The most effective treatment for varicose veins is complete surgical removal of all incompetent veins and perforators by stripping, dissection and resection.[5] A recent comparative study of results from this institution supports the conviction that the ligation and injection method fails to produce as satisfactory long-term results as does complete stripping.[6] However, this extensive operation is avoided purposely in the pregnant patient until after delivery, when it can be done more thoroughly and safely.

The operation of complete stripping of the veins has to be extensive by necessity, and therefore requires several hours of general anesthesia. The congestion of the superficial veins during pregnancy increases the tendency for bleeding during the operation, and even with the most careful hemostasis it is difficult to keep blood loss minimal; any loss of course only adds to the secondary anemia the patient often has. Furthermore, the venous pattern is abnormal because of the congestion, and it may be difficult to distinguish between temporarily distended veins and permanently varicose veins. Thus, the pregnant woman is not an ideal candidate for this time-consuming, elective operation. Instead, it is preferable to postpone the operation until approximately six weeks after delivery, when pelvic anatomy has returned to normal and pelvic congestion has completely subsided. By doing the operation then, discomfort and possible complications such as superficial phlebitis, stasis changes of the skin and continued breakdown of the tributaries will be prevented or minimized during subsequent pregnancies.

The varicose veins of the pregnant patient are managed conservatively with adequate elastic support and periodic elevation of the legs. Elastic support helps prevent swelling of the ankles and distention of the superficial veins, while elevation of the legs helps lower the hydrostatic pressure in the veins. With mild varices, elastic stockings are sufficient support, but with severe varices, elastic bandages (4-inch No. 8 Ace bandages) are more effective, wrapped from foot level and extending upward to compress the leg and thigh. If induration, usually due to superficial phlebitis, cellulitis or stasis, is present, additional elastic compression with foam-rubber pads is very effective. These pads are made from ½-inch foam rubber; the edges are properly beveled, and then the pads are covered with gauze and applied over the indurated areas. When distended and painful vulvar varices are present, local compression with a perineal pad and binder is advisable in addition to frequent rest in bed for symptomatic relief.

For superficial phlebitis, which is a most common complication, especially in the immediate postpartum period, locally applied heat and elastic compression are usually sufficient. Anticoagulant therapy has not been found necessary except in the very rare instance in which thrombosis has threatened to extend into the femoral or popliteal veins. Superficial thrombosed veins are not ligated, as the phlebitis usually subsides satisfactorily with conservative treatment. Stasis dermatitis, an infrequent complication, is treated with antipruritic lotions or wet dressings, in addition to adequate elastic support of the leg when the patient is up. Rupture with bleeding of a small superficial vein is a rare complication. Local pressure and injection of the responsible venule with sclerosing solution are effective measures. Injection therapy during pregnancy is otherwise not used. In essence, a conservative policy is followed until after pregnancy, when all varicose veins can be removed thoroughly by surgical means.

Summary

Varicose veins during pregnancy are managed conservatively with adequate elastic support until after delivery, when a complete stripping operation can be thoroughly and safely performed. This extensive, elective surgical procedure is done preferably when the patient is not pregnant, because a major surgical procedure should not be done upon a pregnant patient except as an emergency.

Massive Bleeding in Diverticular Disease of the Colon

Report of Two Cases

• *Diverticular disease of the colon accounts for an occasional instance of massive melena. Two illustrative cases are presented with an informative discussion of incidence, pathology and therapeutic course of action.*

C. D. ADKINS, M.D.
Minneapolis, Minnesota

THE purpose of this paper is to present a case of massive hemorrhage due to diverticular disease of the colon successfully treated by an emergency colectomy. A second case is briefly presented to illustrate an elective resection for massive bleeding in a hypertensive elderly patient.

Report of Cases

Mr. T. S., aged sixty-three, was first hospitalized in 1954 for gross rectal bleeding. One thousand five hundred cc. of blood was administered to restore his blood volume. Proctoscopic examination to 20 cm. was negative. Barium enema revealed diverticulosis involving the entire colon. He was well until October, 1957, at which time he was readmitted following massive rectal hemorrhage and lower abdominal discomfort. The hemoglobin was 9.3 gm. with 31 per cent hematocrit. One thousand cc. of blood was given. A repeat proctoscopic examination was negative, and a barium enema and air contrast study also negative except for diverticulosis. No further symptoms occurred until March 31, 1958, at which time he fainted in the bathroom following the passage of large amounts of fresh blood by rectum.

On the third admission, the patient was clinically in oligemic shock, with a blood pressure of 86/64 mm. Hg. General physical examination was otherwise negative. The hemoglobin was 11.6 gm. and hematocrit 34 per cent. One thousand cc. of blood was administered rapidly with a blood pressure response of 132/70. The patient continued to pass small amounts of blood clots until fourteen hours after admission, at which time a bloody diarrhea started with each stool measuring 200 to 600 cc. of blood. An attempt at proctoscopy was unsuccessful because of the massive bleeding. Following the administration of 3500 cc. of blood (blood pressure being well maintained), it was obvious that surgical intervention was mandatory. Thus, twenty-seven hours after admission, the abdomen was opened through a generous left paramedian incision. The entire colon was distended with blood. Careful examination of stomach, duodenum and small bowel was negative except for the distal 18 in. of the ileum which contained blood. Palpation of the entire colon revealed no lesions or inflammatory changes, other than diverticula of the entire colon. Because of the marked distention of the colon with blood, I did not feel that colonoscopy would be diagnostic. In view of extensive diverticulosis, a decision was made to do a colectomy and ileoproctostomy. After the resection, a sterile proctoscope was passed distally into the rectum to rule out any site of bleeding from the stump. It should be noted that extreme care was taken to preserve the terminal-most portion of the ileum to preserve maximum absorptive mucosa. Two thousand cc. of blood was administered during the operation. An immediate postoperative blood volume (Evan's blue dye) measured 5160 cc. with an expected total blood volume for his surface area of 5400 cc., with a red cell mass of 2530 cc. and an expected red cell mass of 2580 cc. The patient tolerated the operation very well.

The colon contained 1100 cc. of fresh blood and clots. Grossly, diverticula were present throughout the specimen, being most marked in the sigmoid colon. A small ulcer with an adherent blood clot was found within a diverticulum in the mid-transverse colon. Microscopic sections showed a sharply pitted ulcer, the crater of which was filled with a hyaline mass of blood and fibrin.

A mid-wound separation, without evisceration, was closed under local anesthesia, on the fifth postoperative day. A marked ileus followed and was treated using a long tube. The patient developed mental confusion and irritability after two weeks of nasal suction. Repeated electrolyte studies (sodium, potassium, chloride, CO_2) remained within normal limits. Oral feedings were started on the fifteenth postoperative day and about that time the patient was found to have a positive Chvostek's sign. Following the administration of intravenous calcium gluconate and oral Nilevar, he rapidly improved with discharge on the twenty-fourth postoperative day. Since discharge, the patient has gained 15 pounds of weight and has one or two solid to semi-solid stools per day.

Mrs. M. A., aged seventy-four, was hospitalized on May 24, 1958, following a ten-hour history of profuse rectal bleeding. On admission, she also had clinical evidence of oligemic shock. One thousand cc. of blood was given rapidly after which the patient had no more

Read at the meeting of the Southern Minnesota Medical Association, held at Hutchinson, Minnesota, September 8, 1958.

bleeding and her blood pressure (210/110) was well maintained. During the next several days she complained of epigastric distress plus nausea. Prior to admission, vomiting without hematemesis occurred. She gave a ten-year history of periodic rectal bleeding which she related to hemorrhoids. An upper gastrointestinal series was normal. A barium enema showed marked diverticulosis of the left colon, especially in the sigmoid. Proctoscopic examination three days after admission was negative. On June 5, 1958, a left colon resection was done. Careful examination of the intestinal tract was otherwise normal. The gross specimen revealed only extensive diverticulosis. Microscopically, no ulcerations were found. Her postoperative course was uneventful.

Massive bleeding is a well-recognized but rare complication from diverticular disease of the colon. Bleeding—either occult, mild, or moderate—however, is more common and thus diverticular disease must be included in the differential diagnosis of melena.

Only a small number of reported cases of massive hemorrhage are found in the literature. Mobley and Dockerty[1] reviewed 1470 cases of diverticulitis at the Mayo Clinic between 1940 and 1954. Only one patient had severe hemorrhage; nineteen had moderately severe and twelve had mild bleeding. Noer[2] reviewed the literature from 1942 to 1955 and found forty cases with sudden severe hemorrhage reported in eighteen publications. LeRoyer[3] studied 200 cases of diverticulitis and of that group, 16.5 per cent had melena. In six patients, rectal bleeding was the main complaint but only one required transfusions. Hoar[4] studied 289 cases of diverticulosis and diverticulitis out of which fourteen patients had massive hemorrhage. Two patients required surgical procedures in an attempt to save life. Fallis[5] reported on ninety-four cases of diverticulitis and found twenty-nine patients (41 per cent) with melena; two of these required resection. Of seventy-eight patients hospitalized, because of complications from diverticular disease of the colon, Quinn[6] found thirty-seven (48.7 per cent) were admitted primarily because of hemorrhage. In twenty-three patients (62 per cent), hemorrhage was considered as massive and total colectomy was done as an emergency in two. Rosser[7] noted bleeding in 30 per cent of forty cases of diverticulitis, four of which had spontaneous and massive hemorrhage. Of thirty-five patients resected for diverticulitis of the sigmoid, Boyden[8] stated that hemorrhage occurred in four (11.8 per cent), with hemorrhage being the presenting symptom in three. Knight[9] reported on 289 patients with diverticular disease of the colon. Fifty-six patients (19 per cent) had no other cause for gross rectal bleeding and, of that group, fourteen patients had massive bleeding. Only two patients required emergency colectomy. Turnbull[10] stated that massive hemorrhage occurred in nine of 151 patients (6 per cent) admitted for diverticular disease of the colon. Welch[11] reported on 582 patients observed for diverticulitis of the sigmoid. Out of 114 resections, bleeding was the major indication in five, three of which had massive hemorrhage with one patient requiring a total colectomy because of shock. Brock and Cates[12] each published case reports where emergency colectomy with ileo-sigmoidostomy was done for massive bleeding. Kunath[13] reported on three cases of massive bleeding in which emergency transverse colostomy was done in two, and conservative treatment in one.

Scarborough[14] and DeCosse[15] have emphasized that in patients with diverticular disease who have rectal bleeding, persistent examination (sigmoidoscopic, barium and air contrast studies) must be done to rule out all other sources of melena. In eighty-nine cases observed for one year by Scarborough for rectal bleeding where diverticulosis or diverticulitis had been accepted as the cause, an adenoma or malignant lesion was found in each case after repeated studies. In this same period, sixteen patients were proved to have bleeding from diverticulitis with no emergency resection for bleeding being necessary. DeCosse's experience was similar, and he states: "Our data indicates that diverticulitis is seldom the cause of rectal bleeding and that other sources of the bleeding are likely to be disclosed by intensive study of the patient."

Pathology

In a high percentage of cases where massive bleeding occurs, diverticula involve the major portion, if not all, of the colon.[2,9,12,13,16,17] The exact point of bleeding is not always found. Mobley and Dockerty[1] carefully studied thirty-two resected specimens grossly and microscopically where bleeding had occurred. In ten cases, ulcers were found to be present in one or more diverticula. In eleven cases, gross inspection revealed an ulceration or discolored zone in the mucosa. Isolated case studies likewise have demonstrated ulcerations within diverticula.[17] By injection studies, Noer[2] found an

increased concentration of blood vessels about colonic diverticula.

Active diverticulitis is not always present,[9] although the Mayo Clinic group[1] found diverticulitis to be present in all. It is difficult to accept the pathogenesis of moderate or massive bleeding without ulcerative changes. In the future, more careful gross and microscopic studies may disclose more cases with definite ulcers in the diverticula.

Treatment

Emergency surgery for massive bleeding in diverticular disease is seldom indicated. The majority of patients respond to conservative treatment with initial blood volume replacement, rest and diet.[3,6,18-20] However, when it becomes evident that massive bleeding continues, the type of surgical treatment is not clear. Transverse colostomy,[4,9,13,16] sigmoid resection[4,5] (primary or Mikulicz resection), exploratory laparotomy without definitive procedure,[2,6] ileostomy,[21] and colon resection with ileo-sigmoidostomy[6,7,11,12,22] have all been utilized. Extensive resection in the presence of advanced age, frequently associated hypertension,[18] plus massive hemorrhage, all contribute to a surgical challenge.

What steps can be utilized to arrive at a decision? A preoperative barium enema may localize the diverticular disease to the sigmoid and thus a primary sigmoid resection or an exteriorization can be done. If only the left colon is involved, a transverse colostomy can be utilized if the condition of the patient contraindicates resection. If the entire colon is involved with extensive diverticulosis, a colectomy with ileoproctostomy must strongly be considered. Preoperative and postoperative blood volume studies, along with careful blood loss replacement during surgery, decrease the operative risk. Colotomy and colonoscopy in the presence of an unprepared colon, which is distended with blood, has been found to be of little value in the localization of the site of bleeding.[9] Obviously, a careful gross examination of the entire gastrointestinal tract at the time of surgery is mandatory.

In the recent literature, many writers[11,23-26] tend toward a more aggressive surgical approach in diverticular disease of the colon.

Summary

Massive rectal bleeding, although rare, is a complication of diverticular disease of the colon which may require emergency surgery to save life. In a brief review of the literature, the incidence of some type of bleeding from this disease is variable. In the reported cases of massive bleeding, it occurs most commonly after the age of sixty; repeated episodes of bleeding may or may not occur; hypertension is frequently present; and the diverticula commonly involve the major portion of the colon. The site of bleeding has not always been demonstrated; however, microscopic and macroscopic ulcers have been demonstrated in the diverticula. In non-emergent cases with bleeding, intensive study of the patient must be done to rule out other causes. In the rare case of persistent massive bleeding, the choice of operation must be individualized.

Two cases of massive hemorrhage are reported, one of which required emergency resection to save life and the other was resected electively to prevent a recurrence of bleeding in a patient who possibly could not withstand another massive bleeding episode.

A Clinical Evaluation of the Transaminase Test

ARTHUR H. WELLS, M.D.
Duluth, Minnesota

THE purposes of this clinical laboratory investigation were: (1) to determine the diagnostic accuracy of the analysis of serum glutamic oxalacetic transaminase (S.G.O.T.); (2) to compare this test with the electrocardiogram interpretation, the white blood cell count and the red blood cell sedimentation rate in patients with a clinical diagnosis of myocardial infarction; (3) to learn whether the test was being used for some of the less commonly known and useful diagnostic measures in diseases outside of the heart; and (4) to determine if it is desirable to encourage the use of the test in smaller hospitals where it has not yet been tried. This is an interval report on a continuing study.

The transaminase test appears to be unanimously accepted in the larger medical centers along with the electrocardiogram as a valuable laboratory procedure for the detection of myomalacia cordis. A widely used practically accurate and dependable colormetric procedure which can be performed with reliability in some of the smallest laboratories is available through the use of a commercially prepared kit of standards, reagents and directions.*

A common fear of an insufficient usage of a newly established test in smaller institutions should be weighed against the fact that coronary sclerosis and its complications is now among the most common and most serious diseases leading to admission to hospitals. In our experience, 750 analyses of S.G.O.T. (at $5.00 a procedure) were run in the first year of its introduction in this hospital.

Glutamic oxalacetic transaminase is said to be an intracellular enzyme which catalizes the conversion of the two animo acids, aspartic acid and glutamic acid from one to the other. The diagnostic value of the measurement of transaminase in the serum lies in the fact that necrosis of cells in the heart, liver, pancreas and striated muscle will lead to a release of this enzyme into the blood stream. The small amount of transaminase normally in the serum (up to 40 units) will increase above 50 units because of the extremely high concentration released from relatively few cells involved in the necrotizing or badly injuring processes in these organs. The ratio of G.O.T. in heart muscle as compared to that in the serum has been calculated to be 10,000[7]/1. The test can be run without regard to the time of day or relationship to meals. The enzyme in serum is for most practical purposes stable. There have been many good and useful contributions to the medical literature on the value of transaminase measurements. It is not the purpose of this presentation to attempt even a superficial coverage of these references.

Method and Procedure

The hospital charts of 100 consecutive patients upon whom an analysis for serum transaminase was performed at least once (average 2.25 per patient) were reviewed in detail to obtain the laboratory data and clinical diagnoses. The transaminase test was performed by a fully qualified chemist or medical technologist, using the colormetric procedure cited in the foregoing.

Results

The clinical diagnoses of the 100 patients' records studied can be divided into eighty-nine with complications of arteriosclerosis of the coronary arteries and eleven with miscellaneous disease processes outside of the heart. Of the former group, there were forty patients with a clinical diagnosis of coronary thrombosis and infarction, twelve with questionable thrombosis and infarction, twenty-six with coronary insufficiency (nearly all of whom

Presented at the Northern Minnesota Medical Association Annual Meeting, Detroit Lakes, September 5, 1958.
The work reported here had the assistance of the St. Luke's Hospital Women's Guild, specific recognition being given to Mrs. David Galvin.
*Sigma Chemical Company, 3500 De Kalb Street, St. Louis 18, Missouri.

had a clinical history of coronary disease on previous occlusions) and eleven patients with long-standing cardiac problems with attendant emotional disturbances or conditions not related to pregression of their heart disease.

TABLE I. CORONARY THROMBOSIS AND MYOCARDIAL INFARCTION
(40 Patients)

Test	Positive	Questionable	Negative
S.G.O.T.	28	2	10
E.C.G.	29	11	0*
R.B.C. Sed. Rate (15 mm.—Westgren)	38		2
W.B.C. CT. 12,000	23		17

*Isolated negative tracings in E.C.G. tracings of five patients.

A summary of the findings in the charts of the first group of forty patients clinically diagnosed as coronary artery thrombosis and myocardial infarction or simply myocardial infarction will be found in Table I. In relation to the S.G.O.T. or the transaminase test, "positive" means values above 50 units, "questionable" those between 40 and 50 units and "negative" up to 40 units. In twenty-eight of these forty cases, the test was interpreted to indicate cardiac necrosis. A further study of the ten patients with normal (negative) S.G.O.T. in this group revealed that a single test was run too early or before twenty-four hours after the hour of onset of symptoms in three instances and it was performed too late (after five days) on five patients. In two cases the diagnosis was disputed by consultants and in two other patients a post mortem examination did not reveal myomalacia cordis although the test had been positive.

All forty patients of this group had abnormal, generally multiple, electrocardiogram tests (using twelve leads) while isolated normal sets of tracings were found in five of these patients. In twenty-nine instances, the E.C.G. study was considered diagnostic of myocardial infarction. There were eleven patients with abnormalities in their tracings but not diagnostic of infarction.

The data on the charts of twelve patients with a final diagnosis of questionable thrombosis and infarction are found summarized in Table II. The very important group of twenty-five patients interpreted as having coronary insufficiency (no myocardial necrosis) are condensed in Table III. See Table IV for the findings in the group of twenty-five patients with clinically established coronary disease who were admitted without symptoms of heart disease, other than emotional disturbances. The patients with clinical diagnoses dependent on diseases completely removed from the heart are found on Table V.

Discussion

The validity of this study depends upon the accuracy of the clinical diagnoses. The great majority of the patients had an internist in attendance. Using all of the written recordings the author (pathologist) agreed with the clinical diagnosis in all but a very few cases. The physicians of the patients in this study almost certainly used all clinical manifestations and the laboratory data to arrive at their final diagnoses. For this reason the study cannot logically be used to compare the accuracy of clinical observations with that of laboratory findings, but it does enhance the value of the final diagnosis in lieu of an autopsy. There have not been sufficient numbers of necropsies on patients with estimations of S.G.O.T. in this hospital to date for a satisfactory analysis of the value of the test.

TABLE II. QUESTIONABLE THROMBOSIS AND INFARCTION
(12 Patients)

Test	Positive	Questionable	Negative
S.G.O.T.	4	3	5
E.C.G.	2	8	2
R.B.C. Sed. Rate (15 mm.—Westgren)	11		1
W.B.C.—Ct. 12,000	3		9

Summary and Conclusions

1. This is a clinical evaluation of the transaminase test using the data from the charts of 100 consecutive hospital patients upon whom at least one analysis of serum glutamic oxalacetic transaminase was performed.

2. Within the limits of error of this study, which is directly related to the accuracy of the clinician's final diagnosis, it was found that the test is the best laboratory procedure for the detection of myomalacia cordis ranking with the electrocardiogram as a diagnostic aid.

3. Of the forty patients who were diagnosed clinically as myocardial infarction there were ten who had a single S.G.O.T. test which was in the normal range. Eight of these tests were run either too early or too late for satisfactory results. Twenty-eight of this group of forty patients had posi-

tive tests which were considered indicative of myocardial necrosis.

4. The transaminase test was negative in a satisfactory number of patients without clinically apparent heart muscle necrosis. The two positive and two questionable results in the group of twenty-six patients clinically diagnosed as coronary insufficiency might well be expected and might shed some doubt on these four clinical interpretations.

5. The four elevations of S.G.O.T. in the eleven patients of the miscellaneous (noncardiac) disease group occurred in patients with choledolithiasis, acute pancreatitis and pneumonia with empyemia

TABLE III. CORONARY INSUFFICIENCY
(26 Patients)

W.B.C. 12,000	4		22

and septicemia, all conditions known to produce positive tests.

6. Repeat or "serial" transaminase tests and E.C.G. tests have many advantages. Repeat if the first enzyme test is run within the first twenty-four hours and is negative or if there is any prospect of liver or pancreatic disease, where the elevation remains high after the five days characteristic of myocardial necrosis. In most situations, if for some reason only one test is to be run on a patient with possible myocardial infarction, it should be ordered for from twenty-four to forty-eight hours after the onset of symptoms. Before or after this period, the test may give a false-negative result. However, it is frequently positive within six hours of onset.

7. Based on the apparent fact that "transaminase" is released to the blood stream as the result of cell necrosis with few well-known exceptions (including some cardiac arrhythmias and liver conditions), the test must be considered specific for cell necrosis when compared to the red blood cell sedimentation rate, white blood cell count, C-reactive protein and other less frequently used tests whose results can be and are frequently elevated by a great variety of conditions besides cell necrosis. The non-specificity of the latter tests is borne out by finding an increase of the red blood sedimentation rate in eighteen of the twenty-six patients with coronary insufficiency (no necrosis) and eleven of the twelve patients having questionable thrombosis with infarction (Tables II and III). The white blood cell count was found elevated in seventeen of the forty patients with myocardial infarction (Table I). These tests should be interpreted with great care in cardiac seizures occurring after the first infarction.

TABLE IV. CORONARY DISEASE—EMOTIONAL AND NON-CARDIAC SYMPTOMS
(11 Patients)

Test	Positive	Questionable	Negative
S.G.O.T.	0	0	11
E.C.G.	0	11	0

TABLE V. MISCELLANEOUS DIAGNOSES

Disease	S.G.O.T.	E.C.G.
1. Rheumatic fever and mitral disease	Normal	Normal
2. Compression fracture spine	Normal	Normal
3. Acute esophagitis and gastritis	Normal	Normal
4. Hepatitis(?)	Normal	0
5. Possible dissecting aneurysm	Normal	Abnormal
6. Non-union patella	Normal	Abnormal
7. Pneumonia, empyemia, septicemia	54	Abnormal
8. Cholelithiasis	Normal	Abnormal
9. Acute pancreatitis	260	0
10. Choledolithiasis	180	Abnormal
11. Choledolithiasis	260	Abnormal

8. The S.G.O.T. and E.C.G. tests complement each other and, in most situations, should not be used to exclude one or the other. Each provides a means of specifically diagnosing myocardial infarction with a high degree of accuracy when used with clinical observations.

9. The S.G.O.T. test appears to be particularly valuable in those patients suspected of having complications involving arteriosclerosis of coronary arteries in which the E.C.G. is interpretated as abnormal but not specific evidence for infarction of the myocardium (Tables II and III).

10. The study reveals an almost exclusive use of the transaminase test in this hospital as a means of detecting cardiac disease. There has been confirmed evidence that it is useful for the clinical investigation of active rheumatic carditis, occult hepatitis, other liver diseases—including even small numbers of cases exhibiting cancer metastases to the liver, acute pancreatitis, pulmonary infarcts, pulmonary emboli and in cerebral infarction, if after five days from the onset of the symptoms the spinal fluid is used for the test.

• *An informative discussion of peripheral nerve injuries with emphasis on the use of electrodiagnostic testing and electromyography.*

The Physical Treatment of Peripheral Nerve Injuries

ROBERT W. BOYLE, M.D.
Milwaukee, Wisconsin

Associate Professor, Department of Physical Medicine, Marquette University School of Medicine, and Director, Department of Physical Medicine and Rehabilitation, Milwaukee County Hospital.

DURING World War II and since, there has been an awakening to the care of peripheral nerve injuries. The increase in accident rates of all types since the war has provided more and more cases of peripheral nerve injuries. Granting that safety measures for the prevention of such injuries is the number one industrial and medical problem, the fact remains that the patient with a peripheral nerve injury must be treated.

This discussion does not cover injuries requiring immediate surgical attention but will concern those cases in which some time has elapsed after the emergent care has been accomplished. Thus, little of what is to be said here can help the surgeon who must use his every skill, many times within the first six hours, to save life and limb. He cannot wait for complete degeneration of a nerve to occur before proceeding. His judgment and knowledge must be put to immediate use.

The diagnosis of the injury and its severity is the first thing to be determined. Mild compression, ischemia, stretching and concussion from explosions may injure nerve fibers. Henderson and Traverner[1] have pointed out that the larger diameter nerve fibers suffer damage of this type more easily than do the smaller diameter fibers. Since the majority of these larger diameter fibers innervate voluntary muscle, a paralysis is generally more severe than the sensory loss in the area since the sensory fibers are most generally smaller in diameter. This is a valuable clue to prognosis for it may indicate functional loss of continuity of the nerve fiber rather than dissolution.

In the process of degeneration and regeneration, it is known that when the axons only (not the sheaths) are interrupted, the regenerating nerve fiber finds its proper channel for regrowth. Reneurotization can be expected to be 100 per cent. If the sheaths are separated, but in immediate proximity, the regenerating fibers will locate their distal channels in a large percentage of cases. If, on the other hand, separation of the distal and proximal ends occurs only surgical intervention will bring about proper apposition.

It has been demonstrated that such surgery will allow the regenerating fibers to find sheaths and

Presented at the clinical session of the American Medical Association, Minneapolis, Minnesota, December 2, 1958.

regardless of the previous function of the nerve fiber of that sheath, the new growing fiber will assume the former function if it properly grows to the end organ—be it sensory or motor. Even a motor fiber growing down the channel of a sympathetic nerve will, on maturation, develop a myelin sheath. It must, however, be remembered that this intermixing of the fibers leads to central cerebral impressions which may be confusing. For the sensory cortex may now be connected to a motor end plate by its accustomed usage. This cortical confusion may retard, delay or completely inhibit fine coordinated movements of the fingers, for example, which require delicate sensory impressions followed by complicated muscular responses to effect neuromuscular coordination.

Generally speaking, however, it may be said that the degree of sensory loss in a mixed-nerve injury will not ever be as severe as the motor loss and can indicate somewhat the degree of nerve injury.

Nothing replaces a good history of the injury (if it can be obtained) and the careful physical examination. If loss of voluntary motion is evident on physical examination, it remains only to determine the severity and level of the lesion to outline the course of treatment and determine the prognosis. For help in making these determinations, certain electrical tests have been described.

About 1862, Erb described the first of these tests which now bears his name. It simply involved the application of faradic current to the paralyzed muscle area. If there was a response to faradic stimulation, the nerve to the muscle was still intact. If there was no response, galvanic stimulation was attempted and if the muscle responded, it meant that the nerve was degenerated.

In the instance of faradic current, the nerve only would respond. This has since been shown to be due to the physiologic fact that the irritability of nerve has a threshold which will respond to currents of relatively high voltage and short duration, while muscle will not. The exception is that very high voltage of short duration will stimulate muscle. Generally, the patient cannot tolerate such high voltage if any sensory nerves are intact. Therefore, if induced (faradic) current is applied and a response is evident, the nerve is intact. A known normal area (often the other limb) can be tested to determine the approximate strength of faradic current which will stimulate a normal nerve.

Muscle also is an irritable tissue and if an unidirectional current is applied for a sufficient period of time, the muscle will respond even if it is not innervated. If, however, fibrosis has set in, the muscle will not respond. The response of denervated muscle is not the quick, rapid twitch seen by normal muscle but rather a slow worm-like contraction, which does not relax completely until the current is turned off. This test has been called the "reaction of degeneration" or R.D.

Erb's test is of little prognostic significance because voluntary contractions will be visible some time before irritability to faradic stimulation returns. It should also be noted that because of the physiologic reactions to the denervating process—namely, that a degenerating fiber can conduct and that its motor end plate may be hypersensitive during degeneration, a period must elapse before diagnostic testing can be of any value. This applies to any electrodiagnostic testing. The time lag varies with the length of fiber involved in the degenerative process, but it is generally shown to be about two to three weeks.

During World War II, the incidence of war casualties created a renewed interest in the field of electrodiagnostic testing. With electronic instruments, currents of accurately measured amperages and times could be easily made. Under Pollock and his associates[2] at Northwestern University and Mayfield at Percy Jones Hospital, Battle Creek, Michigan, a series of electrodiagnostic tests was devised. These tests not only offered the earliest possible positive diagnosis but when repeated on the patients at regular intervals were found to have certain values in predicting early reneurotization of the muscles.

The tests, as finally used routinely, involved (1) a strength-duration curve which yielded, automatically, a rheobase and a chronaxie, (2) a reversal of cathode and anode in determining the rheobase, and (3) measuring the cathodal current necessary to produce a tetanus. From the latter two tests, ratios could be evolved and are called the rheobase ratio and the cathodal tetanus ratio.

Progressive determinations of these tests afforded the ability to differentiate between degenerating, degenerated and regenerating nerves. These investigators were able to predict six to eight weeks in advance that muscle function would return. They were also able to determine, at an early date, need for surgical intervention. However, they were not

able to determine the quantitative recovery that might result.

During and immediately after World War II, a new method of diagnosis was evolved. Instead of stimulating with an electric current and observing responses, electrodes were placed on the skin over the muscle or a concentric needle was inserted directly into the muscle and minute action potentials were obtained. This required equipment—including a cathode ray oscilloscope, an amplifier of high fidelity and a method of recording. The action potentials are of the magnitude of 1/1,000,000 volts compared to electrocardiography whose action potentials are of the magnitude of 1/1000 volts. The duration of these action potentials are measured in milliseconds. This apparatus is known as an electromyograph and the diagnostic procedure as electromyography.

With this equipment, it is possible to make a more minute diagnosis of the number of motor units denervated but probably more important, it can prognosticate recovery several months before regeneration is evidenced by voluntary contractions.

The expense of the equipment and the elaborate techinque involved have limited the everyday use of this type of testing to university centers or in areas of specialized concentration on large numbers of patients having neurologic problems.

Electrodiagnostic testing is a laboratory aid to the clinician and not a substitute for a good physical examination and a careful history. It cannot hasten the recovery of the patient nor prevent the degenerating process with its resultant muscle atrophy; only careful supervision and treatment of the patient can bring about the best possible result. As already indicated, the intervention of surgery at the earliest possible moment can assist in earlier recovery which, at best, is going to be very prolonged.

Different diameter nerve fibers regenerate at different rates—the largest growing perhaps as much as 3 mm. per day and the smallest at a rate of less than 1 mm. per day. If the site of the lesion is known and the distance measured to the most distal point supplied by that nerve, an estimate can be made of the expected lapse period before early signs of voluntary motion appear.

The Hoffman-Tinel sign is a useful clinical procedure in following the course of nerve regeneration. By tapping lightly with a single finger over the course of the degenerated nerve, a tingling sensation is set up over the peripheral course of the nerve. As the nerve regenerates, the point of eliciting such a sensation follows the growth and if a record of the growth is kept, one can predict its rate and progress. Napier[3] claims the sign should not be considered irrefutably positive until it can be elicited 10 cm. or more distal to the site of the injury.

General Treatment

As mentioned previously, when the cause of the nerve injury is trauma, such as avulsions, lacerations or crushing injuries, necessitating immediate surgery, time is of the critical essence. The surgeon must use his every skill to restore functional anatomy as nearly as is possible and will find little of value in the material just discussed.

Following surgery to tendons and nerves, the parts are immobilized to keep tension off the delicate sutures. After immobilization, there must be extreme caution in the treatment instituted and parts distal to the sutures must be handled gingerly. As healing takes place without complication, the treatment can be carried out as indicated hereafter.

There is a difference of opinion on the most important part of the treatment. The English school as expressed by Sandifer[4] claims that maintaining range of motion in the joints distal to the injury is most important. If periarticular changes occur which result in loss of passive range of motion, then the weakened recovering muscles will never be of any use in moving the part even if they recover full strength.

In this country, functional splinting is considered at least as important as passive motion (Watkins[5] and Rusk[6]). This does not mean continuous protection; such protection leads to muscle and bone atrophy, as well as to contractures and fibrosis. The splints are removed several times a day for other treatment including passive range-of-motion exercise.

It is often a standard practice to precede the above treatment with heat. Because of the frequent loss of sensation, the use of any form of diathermy is contraindicated as a method of heating. Diathermy output cannot be safely administered in the face of sensory loss. Luminous or non-luminous forms of infrared can be used provided the source of energy is kept far enough away from the part to prevent burning. For extremities, a useful form of heat is water commonly used as whirlpool. Here the temperature of the water can be measured

beforehand with a thermometer. The water should not exceed 100 to 101° F. The use of air ejection agitators provides a small degree of passive motion to the distal immersed parts. The heat is used to increase the circulation and to relax the muscles.

Following the heat, a routine gentle passive motion is used at each joint carefully taking it through its normal range of motion. Force is not necessary and may be harmful in over-stretching shortened paralyzed muscles. With muscle atrophy, the relaxation which may accompany the disorder may lead to excessive lengthening of the tendons and the stronger antagonist may become shortened. If the normal status of the muscle is one of weakness, such as the extensors of the wrist and fingers or the dorsiflexors of the foot and toe extensors, then the stronger antagonist may produce a virtual physiologic contracture which will be extremely difficult to overcome even if recovery should become complete. Even the force of gravity exhibited in wrist drop or foot drop, can be sufficient to produce irreversible damage. This is a leading reason for the philosophy of functional splinting-stretch and keeping stretched the stronger muscles while awaiting the return of muscle power to the paralyzed muscle.

The question of the electrical stimulation of paralyzed muscles has advocates and critics. Clinical and physiologic evidence are difficult to evaluate. Fischer[7,8] and Wakim[9] have demonstrated that there is a delay in muscle atrophy if stimulation is used, but at best, over a long period of awaiting recovery, not over 50 per cent can be prevented. This is based on wet and dry weight comparisons of stimulated and non-stimulated denervated muscle. They do believe, however, that there is a more rapid return to peak strength on recovery. This is not to be misconstrued to mean that a muscle which only becomes 50 per cent reinnervated will have the same strength as one which is 80 per cent reinnervated. They are agreed that electrical stimulation cannot alter in any way the rate of regeneration. It becomes a matter of maintaining more bulk and a faster rate of voluntary recovery. These are, of course, conclusions based on animal experiments.

The matter of what type of current to use and the frequency of stimulation periods must be mentioned. Grodins and his colleagues[10] claimed that a low frequency. (10 to 25 per sec.) slowly rising, alternating current produced the maximum contraction of the muscle with the lowest amperage. Others have used square or rectangular wave forms with and without alternating polarity and obtained equally satisfactory results. Their currents were based on the fact that galvanic tetanus could be produced at low amperages. On one point they all agree: that the contraction should be of a vigorous tetanic type to produce the best results.

Sandifer[4] advocates 100 contractions divided into three periods with at least three-minute rests between periods. In Wakim's[9] experiments, he used varying times and found little difference in their effectiveness. Agreement on daily stimulation seems to be accepted.

The problem of prevention of muscle fibrosis during the denervated state is one in which there is no immediate answer. Reports have been made that muscle denervated twenty years previously by poliomyelitis has sometimes been without fibrosis, while muscle denervated a mere six or eight weeks under the best medical supervision, including electrical stimulation, showed marked fibrosis. It could be that within the previous history of the muscle tissue might rest the explanation. In other words, a muscle which had seen much use and abuse over the years might more easily, during degeneration, regress to a state of fibrosis. There is no proof of this theory but it is being advanced in the field of geriatrics to explain wear and tear on tissues. Another factor may be the disturbed metabolism and blood supply to the muscle. If such were the case, the heat, motion and electrical stimulation should minimize or reduce the fibrosis. Again, there is little evidence to support such a proposition. One more factor might be tissue trophic changes due to altered enzyme mechanisms and the accompanying change in the "trigger mechanism" of acetylcholine at the muscle-nerve junction. The explanation may be found in one, a combination or none of these suggested theories.

The purpose of the treatment is to insure the best possible muscle when reneurotization takes place. Once the muscle can again be moved voluntarily, graded increases of exercise can be instituted as rapidly as they can be tolerated. At this time, occupational therapy is instituted for the disabled part. This occupational therapy should be of such a nature that the patient repeats over and over again, the muscle action necessary to build strength and neuromuscular co-ordination in the paralyzed muscles.

Since many nerve lesions take months for recovery, it has been a common practice to send patients to occupational therapy to learn the activities of daily living and self care while awaiting the return of innervation to the affected part. If there is a possibility that the injury will necessitate a change of occupation, thought should be given at the earliest possible time to vocational rehabilitation. The anticipated new occupation may require neuromuscular skills or education which could be given during the long recovery period.

Facial Nerve Paralysis

(Conduction Type Known as Bell's Palsy)

Facial nerve paralysis is the most frequent cranial nerve lesion for which physical medicine treatment is requested. In 75 per cent of all cases the cause is unknown. There is frequently a history of exposure to cold or trauma but this is not universal. It is thought by some that it is the result of edema followed by ischemia within the narrow canal of the petrous portion of the temporal bone. Other causes include basal skull fracture, infection of the mastoid air cells and surgery of the parotid gland.

The onset is often preceded by pain over the mastoid bone and perhaps tenderness over the insertion of the sternocleidomastoid muscle. Occasionally, an enlarged, tender lymph node may be found between the angle of the jaw and the mastoid.

All the affected muscles, including the platysma, are flaccid and toneless. They are unilateral making the face assymetric even at rest and because of gravity, they sag. Tears trickle over the lower margin of the eyelid and saliva drools from the corner of the mouth. The eyelid descends slightly because of reciprocal inhibition of the levator palpebrum and the orbit rolls up when the patient attempts to close his eyes. Attempted blowing or whistling cannot be accomplished because the cheeks cannot hold air. Drinking fluids results in trickling from the flaccid corner of the mouth and solid food tends to become lodged between the gums and cheek. Loss of taste from the anterior portion of the tongue and increased acuity of hearing with clicking noises may occur if the geniculate ganglion and the stapedius muscle are involved.

A review of 517 cases at Massachusetts General Hospital by Park and Watkins[11] showed 451 or 87.2 per cent to be of idiopathic origin; thirty-one or 6 per cent, traumatic; the same for infection; and, four cases, or 0.8 per cent due to tumor. One hundred and ten cases revealed some gustatory changes. The patients in 87 per cent of the idiopathic cases had a total loss of voluntary motion over the seventh nerve distribution, the other 13 per cent had partial loss.

Electrodiagnosis showed 35 per cent had partial R.D. while 52 per cent had normal reactions. Treatment consisted of luminous heat, or hot packs for twenty minutes, twice a day; light stroking massage; galvanic or faradic stimulation, three times per week; passive exercise until voluntary motion returned, two times a day; and care of the eye, twice a day. Results: 66 per cent, complete recovery; 21 per cent, good; 9 per cent, fair; 3 per cent, poor; and 1 per cent, no improvement. There was a 0.7 per cent recurrence. Patients with normal electrodiagnosis recovered in two to six weeks; partial R.D. patients averaged one month, occasionally two to six months; complete R.D. took three to four months for maximum recovery. Mass action of facial muscles—with distant muscles accompanying activity such as smiling and eye-closing, or stimulating a muscle and a remote muscle also contracting—were frequent accompanying findings.

The treatment follows the procedure set forth above. Stretching of the muscles by the intact muscles of the opposite side of the face, and the force of gravity can be helped by warning the patient about smiling or laughing excessively. Splints can be made from adhesive tape or plastic —the principle being one of trying to keep the angle of the mouth upward.

Since frequently the eye will not close, a patch or night shade can be worn during the sleeping hours, and glasses for protection of the conjunctiva and cornea should be worn during the waking hours.

There is frequent pain accompanying the early stages of facial nerve paralysis. The pain is located just behind the ear. Relief may be obtained by mild heat applied in the form of warm compresses or luminous heat.

The use of gentle stroking massage away from gravity, may help in producing passive exercise. When muscle again comes under voluntary control, the patient can be taught to exercise in front of a mirror. The exercises are usually taught bilaterally because they are easier to do and the cerebral patterns are geared to symmetric activity. These exercises are practiced many times a day until recovery reaches a maximum. While the patient strives for complete recovery, it is common

to have some degree of asymmetry accompanying speech or smiling. In the more severe cases, the mass action is more evident. The muscles become more irritable and electrical stimulation must be discontinued. There is often an onset of tic-like involuntary motions which are annoying. These may be gross fasciculations described in electromyography. Mild heat and gentle massage is given for relief. Emotional stress may make these complications more severe and reassurance and mental relaxation are necessary for mental poise.

Radial Nerve Injury

This is a common condition following resting on crutches (crutch paralysis), resting on a park bench (Saturday night palsy) and accompanying fractures of the humerus in the area where the radial nerve curves close around the humerus. Injuries of the brachial plexus posterior cord will give the most complete type of radial nerve injury. Most often the nerve is injured below the level at which the triceps muscle is supplied so that extension of the elbow is not affected. The resulting lesion affects the extensors of the wrist and fingers giving the well-known wrist drop. Sensory loss is confined to the radial side of the dorsum of the hand.

Electrodiagnosis and electromyography can assist in locating the level of the lesion and whether it is complete or partial. Trick voluntary motion of the finger flexors may produce moderately weak dorsiflexion. Relaxation of the fingers allows the wrist to drop.

Range of motion exercises must be done several times a day. The patient can be taught how to flex and extend each finger, the thumb, wrist and elbow. A functional splint should be kept on when not exercising the parts. This splint should keep the wrist in extension, the metacarpophalangeal joints in flexion and the phalanges in extension. Such a splint is described by Rusk.[12] The splint so-described can be modified when muscle power starts to return so that it can become a part of the exercise program using springs or rubber bands as the opposing force. Because the flexors of the hand and wrist are so strong compared to the extensors, it is important to keep the flexor tendons taut and the extensor tendons relatively short. This is accomplished by splinting in a functional position as described above.

Hydrotherapy in the form of whirlpool with the water temperature at 101° F is an excellent method of assisting adequate circulation. It also appears to relax the muscles both innervated and denervated. The use of electrical stimulation as a form of active exercise may slow down the process of atrophy. It is a helpful method of muscle re-education during the early stages of reinnervation. Once voluntary motion returns, the type and degree of exercise must be increased as tolerated.

At this stage, occupational therapy again becomes essential. As mentioned earlier, the distal delicate motions are the most difficult to attain and the earliest moment of retraining must be used. Incidentally, this is not as important with radial nerve injuries as it is when the ulnar or median nerves are involved, owing to the fact that our most highly developed finger motions are those of flexion. Occupational therapy of the one-handed type is encouraged so that the patient can carry on his activities of daily living independently using one hand. This is especially important when the dominant hand is the one injured.

Recovery, at best, is a long tedious process when one considers that it is about 500 mm. from the mid-humerus to the middle phalanx of the middle finger. At the fastest rate of regeneration (3 mm. per day), it will take about six months for reneurotization and perhaps two months more to recover use of the fingers.

The Deep Peroneal Nerve

Of all the branches of the sciatic nerve, the common peroneal is the most susceptible to injury. It may be injured by stretching, direct blow, pressure or by fracture of the head of the fibula. It is vulnerable because of its superficial course and the bone under it. It is neither protected nor cushioned. The superficial peroneal nerve supplies the muscles of the side of the leg, the peroneous longus and brevis. Sensory loss is confined to the more medial part of the dorsum of the foot. The deep peroneal nerve supplies the dorsiflexors of the foot and the extensors of the toes. Sensory loss is usually found on the dorsum of the foot and the outer aspect of the leg.

Because of the paralysis, there is a foot drop. If the superficial peroneal nerve is intact, there is unopposed eversion of the foot. If both peroneal nerves are involved, there is more inversion with the drop foot. The gait upon walking is quite evident. It is called by Haymaker and Woodhall[13] a "steppage gait"—the distal part of the foot and its outer margin drag, and at the end of the ex-

cursion, the foot tends to strike the ground with an audible "clap." If nerve involvement is not complete, the play or dance of the tendons varies from normal. Because of the atrophy of the muscles which dorsiflex the foot, the tibia stands out sharply like a keel. Tapping of the toes may produce a rebound dorsiflexion which may be misinterpreted as weak voluntary contraction of the toe extensors.

Electrodiagnosis and electromyography can assist materially in locating the level and severity of the lesion. Careful sensory examination will assist in outlining the sensory nerve involvement. It is not uncommon for regeneration to take ten months to a year.

The treatment is essentially the same as that for the radial nerve. Supportive bracing is most essential if the patient remains ambulatory. If the patient is over eighteen years of age, the power of the plantar flexors through the tendon achillis will lead to a shortened heel cord. If this condition exists for even a short period of time above this age, it cannot be stretched manually or by body weight. This is seen not infrequently when a skin-tight or unpadded cast is applied over the head of the fibula and the foot is incorporated in plantar flexion. Heel cord tenotomy may have to be instituted or a lift placed on the heel following recovery.

To prevent inversion or eversion and foot drop, a double bar short leg brace with a Klenzak ankle joint or a 90° (or less) stop built into a simple hinge ankle joint, can be used advantageously to allow the patient to ambulate.

Daily physical therapy of whirlpool or mild luminous heat and passive exercise to maintain range of motion must be instituted. Daily electrotherapy can be used. When reneurotization of the muscles becomes evident, active assistive and active exercise is taught and the amount increased as tolerated. As the muscles grow stronger, tension on the springs of the Klenzak joint can be reduced to put more work on the recovering muscles. Occupational therapy of the reverse treadle type can be instituted as soon as some voluntary muscle contractions return. In most instances, the patient can continue his occupation except if it involves being on his feet continuously or if it involves heavy labor affecting the lower extremities.

There is an interesting phenomenon about the return of function. The long toe extensors return first. This is followed by the tibialis anterior and finally the extensor hallucis longus.

Summary

1. A description of the etiology of peripheral nerve injuries is briefly described.

2. The method and physiology of the use of electrodiagnosis and electromyography in peripheral nerve injuries is explained. Reaction of degeneration and the diagnosis of partial denervation of a nerve are discussed.

3. The reasons for certain types of physical treatment are given and a general outline and rationale for them explained.

4. Three of the most common types of lesions are discussed with the variations in their management.

5. Finally, a word of pessimism: regardless of the type of injury, if there is degeneration, the chances for 100 per cent reneurotization and function of the muscle are exceedingly poor. However, with the body's natural margin of reserve, perhaps 80 per cent recovery or less may be more than adequate.

Some Problems of Liver Diseases in Early Infancy

A long list of possibilities comes to mind when the physician is confronted with an infant who has jaundice and hepatomegaly. The author discusses five diseases that may produce such a picture. Diagnosis is important in some of these conditions to allow adequate treatment before irreversible hepatic damage ensues.

GEORGE B. LOGAN, M.D.
Rochester, Minnesota

DISEASE of the liver is not common in infancy, but it does occur with sufficient frequency that physicians must be aware of its various causes. Hepatomegaly is one of the chief manifestations. Table I lists the various causes of hepatomegaly noted in infancy. From this group of conditions, I have selected five for consideration, namely (1) atresia of the bile ducts, (2) the inspissated-bile syndrome, (3) infantile hepatitis, (4) galactosemia and (5) cytomegalic inclusion disease.

Infants having any of these diseases vary in age from a few hours to a few weeks. They are usually jaundiced, and they have varying degrees of hepatomegaly, splenomegaly or splenohepatomegaly. Some appear to be extremely ill, whereas others do not appear to be ill but are jaundiced. My colleagues and I have encountered infants having these five diseases among residents in southern Minnesota or in the immediately adjoining states.

TABLE I. CAUSES OF HEPATIC DISEASES IN INFANCY*

- Apparent enlargement and anomalies
  - Normal but palpable liver (right lobe only may be palpable)
  - Hepatoptosis
- Engorgement with blood
  - Heart failure
    - Congenital heart disease
    - Paroxysmal tachycardia
- Engorgement with bile
  - Obstruction of the bile ducts
    - Congenital obliteration
    - Inspissated-bile syndrome
- Inflammation
  - Infantile and neonatal hepatitis
  - Septicemia
  - Syphilis
  - Cytomegalic inclusion disease
  - Histoplasmosis
- Hyperplasia
  - Cirrhosis
- Infiltration and storage
  - Erythroblastosis
  - Lipide-storage diseases
    - Niemann-Pick disease
    - Gaucher's disease
      - Acute
      - Chronic
  - Gierke's disease (glycogenosis)
  - Galactosemia
  - Fanconi's syndrome (cystine storage)
  - Letterer-Siwe disease (reticuloendotheliosis)
  - Leukemia (rare)
  - Osteopetrosis (rare)
  - Toxoplasmosis (rare)
- New growths
  - Hemangio-endothelioma (rare)
  - Cancer (extremely rare)
    - Primary
      - Hepatoma
      - Mixed tumor
    - Secondary
      - Metastatic neuroblastoma

*Modified from Logan, G. B.: Significance of hepatomegaly in infants and children. Postgraduate Medicine, 13:469-472 (May) 1953.

Atresia of the Bile Ducts

This almost invariably means atresia of the extrahepatic biliary tree in part or in whole. Atresia of the intrahepatic biliary tree usually is associated with that of the extrahepatic system, but the extrahepatic system occasionally is intact. Atresia of the bile ducts may be included with diseases of the liver because the condition, if it is not recognized soon enough or if the lesion is inoperable, leads to cirrhosis of the liver and subsequently to death. The first sign is jaundice, which usually has associated with it the appearance of light or clay-colored stools and dark urine. A recent review[1] of the experience at the Mayo Clinic disclosed that many patients had the onset of jaundice at the time of birth or within the first day or so of life. Only 10 per cent of the patients in this clinic series were reported as doing poorly at the time of their initial examination at the clinic; the remaining 90 per cent did not appear ill.

Physical examination usually discloses only a jaundiced infant who has hepatomegaly or hepatosplenomegaly. The jaundice persists and, although

it is characteristically said not to vary in intensity, occasionally it may appear to fluctuate clinically, and values for serum bilirubin determined serially may vary by a few milligrams per 100 ml. of serum.

The most important single diagnostic test in our experience is the determination of the amount of bilirubin in the blood. We have found values ranging from 4.2 to 37.5 mg. per 100 ml. of serum, the mean value being 12.8 mg. Others[2] have found similar levels. Nearly all of this is the direct-reacting type. In contrast, Weller[3] pointed out that the amount of bilirubin is of little help in making the diagnosis because the values are often low. However, in our experience, no other condition in patients of this age period will present consistently increased values for direct-reacting bilirubin in the blood.

Measurement of the prothrombin time (Quick) is helpful from a prognostic standpoint. Patients whose prothrombin time is prolonged live a shorter period than do those having normal values. Those whose prothrombin time is prolonged but who respond to the use of vitamin K live longer than do those who do not respond to the use of vitamin K.

Kove and associates[4] recently suggested that measurement of the enzymes glutamic-oxalacetic transaminase and glutamic-pyruvic transaminase may be of value in establishing the diagnosis of atresia of the bile ducts. At present, their report should be considered as only preliminary. Other tests of hepatic function offer little diagnostic help.

Reports in the literature show an incidence of operability in this condition varying from 18 to 25 per cent. In our experience, the incidence of operability has been 22 per cent. By being operable, we mean that the common bile duct may be atretic but that the hepatic duct, cystic duct and gallbladder are patent. All conditions in which the hepatic duct is atretic, regardless of other combinations of anatomic atresia, proved to be inoperable. Intrahepatic atresia also is not amenable to surgical correction. If children having extrahepatic biliary atresia can be operated on successfully before cirrhotic changes have occurred, the outlook for a normal life should be good.

Should the patient's condition not be amenable to surgical treatment, the prognosis for life will be variable; 75 per cent of such patients in the clinic series were dead within eighteen months. However, two lived as long as two and one-half years, one for four and one-half years and one for six years. Thus, one must use some judgment in discussing the prognosis with the parents.

The time to operate is when the diagnosis has been definitely established. It is usually best not to operate before the patient is four to six weeks of age but to make the decision before the child is three months of age. My colleagues and I do not agree with Harris and associates,[5] who prefer to delay the operation until the patient is four months of age. Cirrhosis is an invariable complication of atresia and has been seen in patients as young as two and one-half months. Cirrhosis developed in seven of our patients at five months of age or younger.

At the time of operation, the procedure of cholangiography plus biopsy of the liver is preferable to manual exploration of the biliary tree.[6] The latter is tedious, risky and difficult, and it may lead to an erroneous diagnosis of atresia when the ducts are tiny and difficult to identify.

Inspissated-Bile Syndrome

Considerable disagreement exists as to whether this condition really occurs. It was first mentioned by Ladd,[7] in 1935. The syndrome comprises obstructive jaundice resulting from mucous plugs or inspissated bile in the biliary system. A number of instances have been reported after or as a complication of severe erythroblastosis. However, a number of cases have been reported as instances in which the etiologic factor is unknown. Many of the patients in this latter group have been shown actually to have hepatitis. Harris and associates,[5] and also Gellis and co-workers,[8] thought that the term "inspissated-bile syndrome" is best not used, because it implies that the defect is of mechanical origin rather than a lesion of the hepatic cells. Such an entity does occur, however, and it may be treated medically and sometimes surgically.

The onset is in the early weeks of life. The important symptoms and signs are jaundice, dark urine, light stools and hepatosplenomegaly. The bilirubin may be mostly of the direct-reacting type, but often both direct-reacting and indirect-reacting types are present. Values are about the same as they are in those children having atresia of the bile ducts. The jaundice usually fluctuates. The definite diagnosis can be established only by finding inspissated bile or mucous plugs at the time of duodenal drainage or operation.

Treatment by means of duodenal drainage requires a skilled and patient intubationist. Dehy-

drocholic acid (decholin) may be administered intravenously at the time of the drainage. Duodenal drainage is best not carried out oftener than three times a week. An oral preparation of desiccated bile salts (ketochol) may be given with each feeding for one to three weeks.[9] If one can be sure that he is not dealing with hepatitis and if the jaundice persists, then surgical intervention is advisable.

Infantile and Neonatal Hepatitis

This condition is recognized more often now than it used to be. Most of the reports in the literature concerning its occurrence appeared in the period from 1951 to 1956.[8,10-13] The onset may be from the time of birth on. The etiologic agent most commonly encountered is the virus of serum hepatitis (SH, or virus B). In some instances, it has been proved that the mother is a silent carrier of this infection.[14] It is unlikely that the virus of infectious hepatitis (IH, or virus A) is concerned unless the mother has had infectious hepatitis within a week or so of the child's birth. Hsia and associates[15] made follow-up studies on a large group of women who had infectious hepatitis during pregnancy and found no evidence of hepatitis in their offspring. Other viruses subsequently may be implicated as etiologic agents.

Clinically, the infant appears jaundiced. He may be acutely ill or may have few general symptoms. Hepatosplenomegaly is present. The urine is dark, and the stools may be light. The blood bilirubin is moderately increased. The value for the direct-reacting fraction usually is 50 per cent or more of the total, the rest being of the indirect-reacting type. Values for transaminases are usually increased. It should be remembered that the fractions of the blood proteins as determined electrophoretically are somewhat different in infants than they are in older children and adults.[16] For this reason, the various flocculation tests for hepatic function such as the cephalin-cholesterol and thymol turbidity tests are of little value, the results being rather inconstant. Harris[16] pointed out that the values for the zinc sulfate turbidity test are normally low during the early months of life. Values that would be considered normal in the older child or adult actually represent abnormal increases in an infant a few weeks of age, constituting evidence of hepatocellular dysfunction.

It has been noted that infants who have hepatitis do not withstand surgical intervention very well.[16] If an infant having jaundice is operated on and a patent biliary tree is found but bile is absent, nothing should be done surgically to that biliary tree. Biopsy of the liver should be done to help establish the diagnosis of hepatitis. Kiesewetter and co-workers[17] have reported several instances in which a patient who had hepatitis was operated on and in whom bile was not found in an intact biliary tree. We have had at least one such experience.

Pathologically, multinucleated giant cells have been described in the liver in this type of hepatitis. Because of the description by Craig and Landing,[18] the term "giant cell hepatitis" has come into fairly common use, although these workers did not give the disease this name. Baggenstoss,[19] and Popper and Schaffner,[20] as well as others, considered that the giant cell reaction is simply an infantile reaction to an infection. The term "giant cell hepatitis" probably does not connote any special entity, and its use should be discontinued. The so-called giant cells are apparently multinucleated hepatic parenchymal cells.

The following case report represents an example of severe hepatitis.

Case 1.—A boy, aged thirty hours, from southern Minnesota was brought to the clinic because he was vomiting blood. He was the second child. The father was living and well. The mother had not had any known illnesses during her pregnancies. Subsequently, results of her liver function tests were normal. The delivery had been normal.

When admitted to our service, the infant was somewhat obese and jaundiced; petechiae were present. During a period of ten hours in the hospital, the value for hemoglobin decreased from 12.5 to 10 gm. per 100 ml. of blood. Platelets numbered 36,000 per cubic millimeter of blood, and the leukocyte count was 14,000 cells, of which 63 per cent were polymorphonuclear. The value for bilirubin was 13 mg. per 100 ml. of serum, and all of it was of the indirect-reacting type. A clinical diagnosis of septicemia was made.

Treatment was the use of antibiotics and blood transfusion. The child died ten hours after admission. Two blood cultures taken during life subsequently were reported as giving no growth of organisms. Pathologically, the liver presented the appearance of acute hepatic necrosis, the cause of which was undetermined.

The mortality rate of neonatal hepatitis is high and though some infants having hepatitis recover with only supportive treatment, cirrhosis may be a complication or sequel, as in the following case.

Case 2.—A twenty-month-old boy from northern Iowa was brought to the clinic because of lifelong jaundice and

hepatosplenomegaly. He had been surgically explored in another hospital when he was seven weeks of age; biopsy of the liver at that time showed hepatitis, many giant cells being present.

When he was examined at the clinic, the liver and spleen extended 7 and 5 cm., respectively, below the costal margin. It was thought that special treatment would not be of value.

He was examined again when he was almost six years of age. His appetite had been poor. He had had frequent colds, his spleen had greatly enlarged, and prominent veins had developed in the abdominal wall. The jaundice had disappeared.

The edge of the liver was palpated 3 to 4 cm. below the costal margin, and the spleen extended to the iliac crest. Esophagoscopy failed to demonstrate any varices; however, he bled afterward from the esophagus.

A diagnosis of cirrhosis with portal hypertension was made. A splenorenal shunt was established surgically. Biopsy of the liver was interpreted by the pathologist as showing extremely severe cirrhosis.

A younger sister of this patient apparently had hepatitis at the age of three weeks; she is now well, and results of her liver function tests are normal.

Galactosemia

This is a congenital familial error of metabolism. The condition may be of variable severity. Most infants so affected display evidence of the disease in the early days of life. However, symptoms do not develop in some until later. The onset usually follows the first feeding of milk. After this, the infant at times has difficulty in feeding and fails to thrive; hepatomegaly develops and jaundice subsequently appears. Loose stools may be noted. Cataracts may develop later. Enlargement of the liver and jaundice usually are noted after several weeks.

The value for bilirubin is moderately increased; the direct-reacting type constitutes somewhat more than 30 per cent of the total, the rest being of the indirect-reacting variety. The diagnosis is made by finding a reducing substance in the urine that is galactose, not glucose. It is not detected by use of paper strips for sugar analysis (tes-tape), but it is revealed by Benedict's test. Amino-aciduria also occurs, and albuminuria is present almost constantly. The urine is not dark, and the stools are normally colored.

The treatment is to stop the use of milk and all milk products. Galactosemia is caused by a defect in the enzyme uridyl transferase. The metabolic pathway of galactose is briefly shown in Table II. It was formerly thought that the toxic agent was galactose, but Komrower and associates[21] have demonstrated that it is really an accumulation of galactose-1-phosphate or one of its metabolic products and not galactose itself.

Cytomegalic Inclusion Disease

This infectious process may occur in children of any age; however, it has been reported in a number of babies in the neonatal period. Those who become infected and who give clinical evidence of the infection in the newborn period are more commonly premature infants.[22] The infection is usually fulminant. The onset is often within the first twenty-four hours of life. The infants become jaundiced and lethargic, displaying petechiae and ecchymoses. The spleen or liver or both become enlarged, the splenic enlargement usually being out of proportion to that of the liver. The picture is that of septicemia or a generalized infection. In a series reported by Medearis,[22] in 1957, three fourths of the patients were jaundiced and had a hemorrhagic diathesis, and two thirds of the babies had an enlarged spleen or liver or both.

This infectious disease is caused by the salivary gland virus, an infectious agent that is rather widespread. Regardless of the cause of death, 10 per cent of all infants on whom necropsy is done have evidence of inclusion bodies in the parotid gland. This finding has been taken as evidence of infection by this virus, which is pathogenic for the human.

The value for bilirubin in this disease usually is moderately increased, but sometimes greatly heightened levels are seen. The direct-reacting type makes up from 25 to 75 per cent of the total

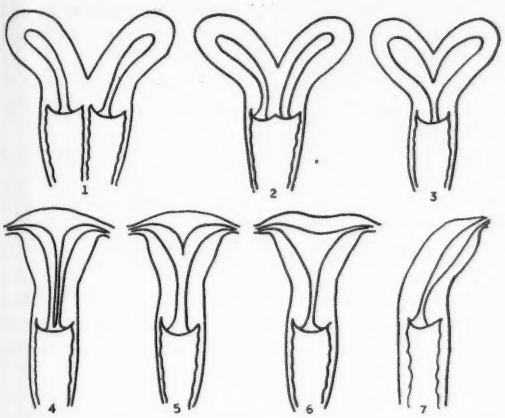
amount. Most of the infants with this infection have involvement of the kidneys. Wyatt and coworkers,[23] in 1950, first reported a test in which the urine is examined for the presence of cells containing inclusion bodies. This procedure is of great aid in the differential diagnosis in any infant who has the afore-mentioned clinical picture.

Treatment is of dubious value. The prognosis in general is extremely poor. Margileth[24] reported an instance of recovery from this condition, the infant being treated with cortisone, gamma globulin and antibiotics. However, the child subsequently was mentally retarded and apparently not robust. Birdsong and associates[25] reported another case in which recovery took place. The infant was treated with vitamin K, penicillin and prednisolone.

Histopathologic examination discloses inclusion bodies in the kidney, liver and lungs; they also are sometimes found in the pancreas, thyroid, brain and salivary glands.

Summary

Disease of the liver, although not common in early infancy, does occur and requires prompt and accurate diagnosis. Hepatomegaly is one of the chief manifestations. From among the various causes of hepatomegaly in infancy, this paper considers five conditions, namely, atresia of the bile ducts, the inspissated-bile syndrome, infantile and neonatal hepatitis, galactosemia and cytomegalic inclusion disease.



Children who have any of these diseases usually are jaundiced. The spleen also may be enlarged, in addition to the usual hepatomegaly. Some of the patients are extremely ill, whereas others appear rather well except for jaundice. Establishment of the correct diagnosis before irreversible hepatic damage has occurred is important as a guide to the proper surgical or medical treatment.

Septate Uterus with Abnormal Bleeding

E. E. ZEMKE, M.D.
Fairmont, Minnesota

Figs. 1-7. (1). Uterus Didelphys, (2). Uterus Duplex Bicornic Bicallis, (3). Uterus Bicornis Unicallis, (4). Uterus Septus, (5). Uterus Subseptus, (6). Uterus Arcuatus or Cardiformis, (7). Uterus Unicornis.

It is always well to keep the diagnosis of a duplicated uterus in mind, especially in cases of vaginal discharge, bleeding and miscarriage.

CONGENITAL abnormalities of the female genital tract are not infrequent. Failure of fusion of the Müllerian ducts, gives rise to a variety of uterine anomalies. Failure in development may also occur in the vaginal tract as a persisting septum of the vagina. One of the simplest classifications is that of Jarcho.[1]

1. *Uterus Didelphys.*—A complete duplication of the vagina, cervix and uterus, probably the rarest of deformities. During a twenty-five-year period in the New York Lying-in Hospital as reported by Smith, only four cases of uterus didelphys were seen in 114,243 consecutive obstetrical patients, admitted (Fig. 1).

2. *Uterus Duplex Bicornis Bicallis.*—Here the duplication of the vagina is absent (Fig. 2).

3. *Uterus Bicornis Unicallis.*—Here there is one incomplete fusion of the fundus segment producing widely separate horns (Fig. 3).

4. *Uterus Septus.*—Here there is failure of fusion with a septum which extends the entire length of the uterus (Fig. 4).

5. *Uterus Subseptus.*—Here fusion is incomplete producing a septum in the upper one-half of the uterine cavity (Fig. 5).

6. *Uterus Arcuatus or Cardiformis.*—This apparently is the most frequent uterine deformity (Fig. 6).

7. *Uterus Unicornis.*—Here there is only one Fallopian tube (Fig. 7).

In the writer's experience three cases of abnormalities of the female genital tract have been seen.

1. On premarital examination a septum of the vagina extended throughout the vagina but was not attached to the cervix. The septum was removed with a resulting normal vagina.

2. A married woman came to the office complaining of leukorrhea. On examination, two individual and complete uteri were found with a

Presented at the Annual Meeting of the Southern Minnesota Medical Association, Hutchinson, Minnesota, September 8, 1958.

normal single vagina. One cervix had an erosion, the other cervix was normal. The erosion was cauterized and the leukorrhea cleared up promptly.

3. The third is the patient whose case is reported here.

Fig. 8. Drawing of suspected abnormalities in the case of Miss R. S.

Report of Case

Miss R. S., a white woman, aged nineteen, was seen April 19, 1958. Her complaint was generalized weakness and vaginal bleeding for the previous two months. She used up to eight to ten napkins daily. Her past history was essentially negative. The menarche had occurred at age fifteen and had always been regular (twenty-eight days) lasting three to four days with moderate bleeding until these past two months.

General physical examination revealed a very pale, well nourished, well developed white woman weighing 120 pounds. Blood pressure was 140/80 mm. Hg., pulse 92, respirations 20, temperature 98.6°.

Laboratory data were as follows: hemoglobin 3.6 gm. (20 per cent); white blood count 6,250 per cm. mm.; red blood count 1,900,000 per cu. mm. Urinalysis was negative.

Pelvic examination revealed the presence of a double vagina, double cervices and the existence of a suspected double uterus. Each vagina admitted one finger with the right vagina slightly larger in diameter. They were separated by a septum about 0.5 cm. in diameter which extended from a point about 1½ cm. within the hymenal ring to the cervices. This septum resembled the lateral vaginal wall in appearance and in elasticity. The cervices were nulliparous and equal in size. There was bleeding from the right cervix but none from the left. The uterus was of normal size and seemed to be only one corpus.

The patient was hospitalized immediately because of severe anemia. Additional blood study revealed a hemoglobin of 3.4 gm.; red blood count of 2,030,000; Type O, RH positive. Eight pints of blood were given by transfusion over a period of eight days. Vaginal bleeding lessened after the patient received the first pint of blood and active bleeding stopped on third hospital day. The hemoglobin value on the third hospital day was 52 per cent, RBC 2,750,000; blood smear showed moderate hypochromasia, moderate polychromasia, moderate anisocytosis and poikilocytosis. On the eighth day, the hemoblogin was 11.5 gm. or 74 per cent, RBC 3,500,000, blood pressure 134/84, pulse 80. Patient was taken to surgery on the tenth hospital day.

Under sodium pentothol anesthesia, the vaginal septum was removed. The right cervix was dilated and curetted, with about 2 cm. of tissue being obtained. It was felt that there was a definite septum between the uterii. Postoperative recovery was uneventful.

The pathologic specimens examined by Dr. R. Hebbel of the Pathological Department of the University of Minnesota were reported as follows: (1) Microscopic section of a specimen from the vaginal septum shows fibrovascular connective tissue with a squamous epithelial covering on either side. (2) Microscopic section of the curettings from the right cervix shows a proliferative endometrium with some areas of benign hyperplasia. (3) Microscopic section of the curettings from the left cervix shows a proliferative endometrium.

The patient has had two normal menses since surgery. Hysterosalpingogram shows a double uterus with a single Fallopian tube from each uterus.

Discussion

Many abnormalities of the female generative tract may occur. Of particular interest in case No. 3 is the development of uterine bleeding in one uterine cavity of a septate or duplex uterus. The material obtained by curettage demonstrated that bleeding was due in this case to a benign hyperplasia. Reports of similar nature appear in the literature, such as reports showing endometrial carcinoma arising in one side of a duplicate uterus. The case presented here would seem to suggest that there must be some factor inherent in the endometrium itself to permit the hormonal changes usually considered as the cause for benign hyperplasia to occur in one side of this duplicated uterus and permit the other uterine cavity to maintain a normal endometrium.

Conclusion

Three cases of uterine abnormalities have been presented, including one case of abnormal uterine bleeding occurring in only on side of a duplicated or septate uterus.

The diagnosis and management of the abnormal bleeding has been discussed.

The suspected abnormalities of this case are shown by this drawing (Fig. 8).

Acute Chylous Peritonitis

DARWIN K. HOLIAN, M.D.
Albert Lea, Minnesota

IN 1954, Hoffman[1] reported the twenty-fourth case of acute chylous peritonitis requiring laparotomy. Along with a review of the previous literature, Madding et al[2] reported the twenty-fifth such case in March, 1958. In addition to being a rarely encountered phenomenon, the following case is unique in that a large chylous tumor was encountered which appeared to be causing infarction of the associated small intestine.

Case Report

L. C., aged thirty-eight, white, single carpenter, was admitted to the Naeve Hospital, Albert Lea, Minnesota, on February 7, 1957. He stated that the day prior to admission he had noted the onset of a crampy lower abdominal pain shortly after breakfast. He did not feel nauseated and did not vomit. By afternoon the pain was better but again it started after eating a light supper. This pain persisted through the night. On the day of admission he stated that he had had a normal bowel movement. No urinary complaints were registered. He was now quite nauseated but did not vomit. The pain was now steady and localized to the right lower abdomen.

Past history revealed a gastric ulcer in 1948 which had responded well to medical management. No epigastric distress was now noted except when eating fatty or spicy foods. He had had no operations and no previous hospitalizations.

Physical examination showed a lean, white man in only moderate distress. Blood pressure was 120/70 mm. Hg.; pulse, 76; temperature, 99° orally. The eyes, ears, nose and throat were normal. The neck showed no abnormality. The chest was clear to auscultation and percussion. The heart was of normal size and no murmurs were heard. The abdomen was relatively rigid but when not being palpated, loops of bowel could be seen through the abdominal wall. True muscle spasm was present on the right side and the maximum point of tenderness was over McBurney's point. Bowel sounds were absent. No masses were felt. The liver, kidneys and spleen were not palpable. Rectal examination revealed a normal size prostate and no masses. Tenderness was elicited bilaterally.

Laboratory studies showed a hemoglobin of 15.5 gm., hematocrit 49, white blood count 12,300 with 74 per cent polymorphonuclears, 25 lymphocytes and 1 eosinophil. Urine specific gravity was 1.018, negative albumin, sugar and microscopic. Chest x-ray showed normal heart and lung shadows. The scout film of the abdomen was not remarkable. No evidence of small bowel gas or bowel obstruction pattern was noted.

Diagnosis of acute condition of the abdomen was made, most likely on the basis of an acute appendictis. A premedication was given and the patient was prepared for the operating room.

Under general anesthesia, a McBurney incision was made and immediately upon entering the peritoneal cavity milky fluid was encountered. The presenting small bowel was found to have dilated lacteals with chyle oozing from the mesenteric surface. Palpation through the incision revealed a mass in the right upper quadrant so the wound was quickly converted to a Harrison-Kripps type of incision and the mass observed directly (Fig. 1).

Presented at the annual meeting of the Southern Minnesota Medical Association, Hutchinson, Minnesota, September 8, 1958.

The mass was found to be a lipoma-like tumor 10 by 20 cm. in size within the mesentery of the proximal small bowel. It was filled with chyle which oozed freely from its surfaces. The size and pressure of the mass appeared to be obstructing both venous and arterial blood as evidenced by an early infarction of the bowel.

Within the involved mesentery, near the axis of the superior mesenteric artery, large nodes were palpated. It was believed that the primary cause of the mass and the lymphatic obstruction could be a lymphoma. Therefore to relieve the involved small bowel and enable a diagnosis to be made, a segmental resection of the intestine was performed (Fig. 2). The entire segment of involved mesentery (to its origin near the superior mesenteric artery) was removed with the intestine and mass. This, unfortunately, was not the only involved area of lacteal engorgement, but owing to the massive swelling of the entire radix, it was not thought advisable to attempt further exploration of the thoracic duct structures. The appendix was removed in the usual fashion and the wound closed anatomically without drainage.

Nasogastric suction was instituted while the patient was still in the operating room and he was returned to the recovery room in good condition.

The postoperative course was entirely uneventful. Gastric suction was discontinued in twenty-four hours and an afebrile course followed with an increasing low-fat diet. He was discharged on the ninth postoperative day after the sutures had been removed from a well healed wound.

The pathologist reported that the mass, when cut, contained large amounts of milky fluid causing the tissue to partially collapse (Fig. 3). This left a spongy appearance which could not be sharply demarcated from the surrounding mesentery. The mucosa of the intestine was thick and edematous, while on the serosal surface, the lymphatics were outlined as fine, white lines or whitish plaques. The mesenteric nodes were enlarged and when cut had a bright yellowish color.

Microscopically, the mesenteric tissues showed edema and a marked dilatation of the lymphatic vessels was seen to form small cysts. However, no true angiomatous character was noted. The intestine showed marked dilatation of serosal and mucosal lymphatics and some edema of the mucosa. Sections of the nodes showed small follicles separated by greatly distended sinusoids which were filled with phagocytic reticular cells and scattered foam cells.

Comment

The lymphatic drainage of the intestine goes *via* the lacteals to the cisterna chyli, the lower sacculated area of the thoracic duct. It lies in the area of the first and second lumbar vertebra. The thoracic duct courses upward along the thoracic spine to finally empty into the venous system at the junction of the left subclavian and internal jugular veins.

Blalock[3] and McGregor[4] report that ligation of the thoracic duct anywhere in its course will not cause a rupture of the distal lymphatic system. This is probably due to the diversion of the lymphatic drainage to the smaller, but effective, lymphatic system which drains the right chest and empties into the right subclavian system.

It is, therefore, postulated that the patient's obstruction sighted here must have been in the lacteal system prior to the cisterna chyli making diversion of lymph to the right lymphatic system impossible or at least delayed.

Causes of acute chylous ascites are listed as (1) obstruction due to malignancies or animal parasites (2) injury or division of the duct or (3) local inflammatory swelling about the proximal lacteals. However, of the twenty-five reported cases, 44 per cent have had no known etiology. One third were diagnosed preoperatively as acute appendicitis.

If one were able to diagnose the condition preoperatively, laparotomy could be avoided. Of the twenty-five cases now reported only one mortality was recorded. Drainage of the peritoneal cavity does not affect the outcome. The author has had one previous case where the patient presented himself with an acute cystic hygroma-type mass of the left supraclavicular area associated with acute abdominal pain. A preoperative chest x-ray revealed fluid in the left pleural space which was aspirated and found to be chyle. A laparotomy was not performed and recovery was uneventful with the use of antibiotics and application of diathermy to the supraclavicular area.

Summary

1. Acute chylous peritonitis is a rarely encountered disease which ordinarily has a good prognosis.

2. Diagnosis is rarely made preoperatively unless a chylothorax is associated.

3. Etiology is unknown in almost half of the cases.

4. A case of acute chylous peritonitis is presented. Associated with the peritonitis was a cystic hygroma whose pressure was appearing to cause infarction of the small intestine.

THE NEW DEAN

At the University of Minnesota, the appointment of deans is a responsibility of the President and the Regents. In arriving at recommendations for such appointments, however, the President relies to a great degree upon the advice of the faculty of the school or college concerned.

To advise him in the selection of a new Dean for the College of Medical Sciences, President Morrill appointed an able and representative faculty committee, and then personally attended almost all of the meetings of the committee. The committee sought the advice of distinguished medical educators throughout the country and conferred with committees of the State Medical Association and of the alumni of the Medical School.

Adequate time was allowed for thorough and exhaustive consideration of all aspects of the situation, the result of which was a recommendation that Dr. Robert B. Howard be appointed to this position. President Morrill concurred in this recommendation and presented it to the Regents who in turn made the appointment.

"Bob" Howard needs no introduction to the physicians of Minnesota. He is one of us. His father was a physician who, for many years, carried on a general practice in Saint Paul. "Bob" attended the public schools of Saint Paul and the University of Minnesota, graduating from both the Arts College and the Medical School with honors. This was followed by graduate work, leading to a Doctor of Philosophy degree in internal medicine. After two years of military service with the United States Air Force, Dr. Howard returned to the Medical School as an instructor in medicine. This was followed in 1951 by his appointment as Director of the Department of Continuation Medical Education, a position vacated by Dr. George Aagaard when he resigned to accept the deanship of Southwestern University Medical School in Dallas, Texas.

As Director of the Department of Continuation Medical Education, Dr. Howard worked closely with the State Medical Association, many county societies, the Academy of General Practice and various specialty groups. His imaginative and enthusiastic leadership and his friendly effective cooperation with medical groups gave him a widespread and favorable acquaintance among the physicians of Minnesota and the Northwest.

During Dr. Howard's years as Director of the Department of Continuation Medical Education, I came to have a high regard for his keen and active mind, his earnestness, idealism and resourcefulness, his dedication to the job and his warm friendly personality.

Recognizing these qualities, I was immensely pleased that he was selected to carry forward the work to which I dedicated a major portion of my life, work in which he will have the invaluable assistance, as I have had, of a charming, devoted and efficient wife. He also will have the loyal support of an able medical faculty, of the alumni of the medical school and of the physicians of the State.

With these assets and this support, I am certain that under the new Dean, the future achievements of our Medical School in the fields of education, of research and of service will continue to be distinguished and to reflect credit upon the University, upon its alumni, and upon the State of Minnesota.

This being true, I congratulate the University upon the selection of Dr. Howard, and I congratulate Dr. Howard upon the tremendous opportunity for constructive leadership which has been presented to him.

HAROLD S. DIEHL, M.D.

RISK OF TRANSFUSION OBVIATED FOR MANY PREGNANT WOMEN

The problem of anemia associated with the pregnant woman is a formidable one. Earlier, this anemia was called a "physiological anemia" or a "dilutional anemia" and was ignored by many. The maternal mortality percentage was in part due to severe anemias. As our knowledge progressed, it became evident that the pregnancy anemias were for the most part iron deficiency anemias.

The history of iron in medicine dates back to the Roman soldiers who came from the battle field weak from blood loss and gained strength from drinking wine to which had been added rusty

nails. It is an amazing fact that this metal was introduced as a therapeutic agent as a result of the association of ideas in the minds of men that iron meant strength and protection, and hence, it would undoubtedly be of value in treatment of persons who suffered weakness from any cause.

Iron preparations are available today in a wide variety of forms and almost every drug manufacturer lays claim to a superior product. The fact that is not stressed is that the body has a limited faculty for the absorption of iron and it must be supplied over a relatively long period of time to meet the demand. Human nature is not imbued with the powers to remember to take a pill four times a day for many months.

When anemia is found during pregnancy, the time available for treatment is limited; and if not discovered until late in pregnancy then many physicians arm themselves with the wares of the blood bank and proceed. As evidence, the number of transfusions in 1959 is expected to reach six million units. Whole blood is a precious commodity and an invaluable therapeutic agent. In the field of obstetrics, catastrophic complications arise where the immediate administration of blood, frequently in large amounts, is imperative. It is not this necessary administration with which we are concerned, but it is the elective transfusions given the gravida in the prenatal period.

The use of blood in obstetrics was the subject of a recent report from the Parkland Memorial Hospital in Dallas. A review of the use of blood in gravid patients showed that for every 100 deliveries there were 50 pints of blood used. Transfusion therapy of this magnitude was costly, hazardous to the patients and did no more than temporarily correct the underlying defect which caused the anemia. During the past year, only seven pints of blood have been used for every 100 deliveries. This is a reduction of 85 per cent, or 2,046 pints of blood saved.

The reason behind the dramatic reduction in the administration of blood to obstetrical patients is parenteral iron. Iron in the form of iron dextran complex was introduced by the English and in excess of 7,000,000 injections have been used in that country and probably an equal number in this country. Iron deficiency is the defect in the great majority of anemias of pregancy. The fetus and blood loss at delivery withdraws 500 mgm of maternal iron which amounts to half of the normal woman's reserves. However, it is estimated that 40 per cent of the adult female population is anemic to some degree. Chronic blood loss, diet fads, gastric anacidity, hypothyroidism, chronic infection and pregnancy are important causes of the anemias.

A report from Hermann Hospital, Houston, Texas, in a series of obstetrical patients treated with intramuscular iron (Imferon) showed an average hemoglobin of 9.0 gms. initially and after six weeks therapy the average hemoglobin was 12.0 gms.

The safety of the product has been verified. Occasionally, transient local soreness and staining of the skin are noted.

For some years, it has been accepted practice to admit all severely anemic gravidas to the hospital for one or more transfusions. The judicious use of iron dextran in some areas has all but eliminated these admissions. It is advocated that oral iron be used in the mild iron deficiency anemias and parenteral iron in the more severe forms where iron stores are depleted. With the use of this therapy "transfusion reaction" will become a less common addendum to the final coding diagnosis on hospital charts of obstetrical patients.

H. L. McCLANAHAN, M.D.

HOW DOES YOUR RECEPTION ROOM LOOK TO YOUR PATIENTS?

Most physicians very naturally may not see the place where their patients wait because they come in the side door and depend on someone else to look after the reception room. It is the intent of this article to call attention to this often neglected phase of medical practice.

There is a trend today toward more spacious reception rooms, attractively decorated and comfortably furnished. Many doctors who have been hampered for years by inadequate quarters are moving into larger offices. Some have even built very attractive offices in outlying areas where parking space is not at a premium.

Without being argumentative, let us leave the question of location in a downtown Medical Arts Building, as compared to a suburban location, with the remark that there are advantages in both. The type of practice and locale of patients would be determining factors.

The problem of doctors moving into new quarters is relatively simple. They can start from scratch and do an excellent job of eliminating

deficiencies of their previous offices. Those who are forced to stay where they are have a more serious problem. Consequently, we shall discuss the two problems separately.

The doctor moving into a new location can solve his problems quite easily. He can start by planning a reception room of 16 to 24 square feet per seating unit, depending upon the type of practice and the length of time patients must wait.

As an example, a single doctor might provide seating for twelve in a room 12 by 16 feet. A clinic might provide for twenty to twenty-five in a room 22 feet square. An L-Shaped single room of similar space also lends itself to good arrangement. Single units of seating are preferable to two and three-seater settees.

Arrangement of the room in seating groups of two, three or four is desirable, as compared to the straight-line technique. A patient may gain a certain degree of privacy through such an arrangement. If you must have straight lines of chairs on each side of the room, break them up with magazine tables, planters or a partition.

There is a tendency to crowd chairs together too closely. A distance of 8 to 10 inches between chairs will allow your patients to sit down, move about and rise without bumping those on either side. Think of those who are shy or nervous, or worse yet, have some skin affliction, or are crippled in any way. A measure of privacy is priceless.

Chairs in a reception room should be comfortable. A combination of deep lounge chairs and higher straighter chairs is desirable. Some people have difficulty arising from lounge chairs and prefer the higher chair. Upholstery should be leather or imitation leather, particularly if the room is air-conditioned. This type of upholstery is easier to keep clean and will appeal to your patients as being more sanitary.

Ample space should be provided for outer wraps. Many waiting rooms are cluttered with wraps on chairs. Provide your patients with an office valet on which to hang their outer coats. Valets are relatively inexpensive and are available in sizes for either six or twelve coats. Your room will be improved if you can partition the coat room or hide it by an attractive planter.

Many doctors are forced through lack of available space, a long lease, or other reasons, to remain in offices where they cannot do the kind of renovations they would like. However, there are many things that a doctor can do to improve his present quarters.

Quite often one office will be larger than necessary, and others will be cramped. Moving of partitions is not expensive, and even small changes sometimes work wonders.

In such cases, a doctor can very often obtain very practical advice on an economical basis. Your office supply and office furniture dealer can be helpful in making suggestions, and his only fee would be the profit on whatever merchandise you might purchase.

The entire approach to arrangement of reception rooms should be on the basis of making the patient feel at ease. Patients are inclined to be tense whenever there is a question about their health. A waiting room that is pleasing, comfortable and relaxing should pay off handsomely in time-saving and retaining patients.

R. G. Scott

THE THIRD PARTY—FRIEND OR FOE?

The delicate nature of my subject is self-evident. In many areas of the country, controversy between the medical profession and a third party has been bitter and a solution is still not in sight.

It is my purpose in these observations to relate to you some historical facts about the socioeconomic aspects of the third party in medicine with which I am familiar and their significance to the medical profession here and elsewhere.

THIRD PARTY DEFINED

First of all, I should like to explore definitions of the third party. One of the outstanding physicians in Pennsylvania, a Past President of the American Medical Association, gave me this definition, which I for one am willing to accept: "Economically, the third party is anyone or any organization that arranges in any way to pay for professional services rendered a patient by his physician."

In gathering material for this presentation, I wrote thirty-one Washington physicians for their definitions and other pertinent information. Several of them called me on the telephone and wanted to know what the third party was. One asked me if it was a new political party. Some went along with the definition already quoted. Others

Reprinted by permission from Medical Annuals of the District of Columbia, August, 1958.

offered some which were quite unique, such as the physician who would include any one of the following as a third party: nurses; laboratory, x-ray, or physical therapy technicians; parents of a minor; adult children of an aged and infirm patient, whether appointed guardians or not; courts (in psychiatric cases); hospitals; insurance carriers; public health officials, and many others.

In a recent newspaper release, the Blue Shield Commission insisted that its organization was not a third party because it is "of the profession itself." Personally, I do not agree. The fact is that Blue Shield Plans act as intermediaries, collecting dues from subscribers and paying physicians, usually in accordance with a fee schedule.

Lest I be misunderstood, this is not intended as a criticism of Blue Shield. After all, as secretary of one of its Plans I am well aware of the unique relationship which exists between this organization and the medical profession.

So much for definitions. Being primarily concerned with the economic aspects of my subject, I will accept the first-mentioned definition, that a third party is any individual or organization that assumes the responsibility for paying a physician for his services to a patient.

I need hardly remind some of the older physicians that third party medicine has been on the medical scene a long time. It has been the heart of many controversies, within and without the medical profession, for the past three decades or more. For better or for worse, it has flourished and become a major factor to be reckoned with by the medical profession.

Why has this growth occurred? There is no simple answer to that question, but a look into the past will give us some clues.

MEDICAL CONTROVERSY IN THE MAKING

Just a month before the disastrous stock market crash in 1929, I was employed as an executive secretary of a large county medical society in Milwaukee, Wisconsin, which is an industrial city. Although I had had eight years' experience as business manager of a medical clinic, the larger economic problems of medicine were new to me. I soon made some important discoveries.

First, there appeared to be a "revolution" in the making where methods of providing and paying for medical care were concerned. The now historic five-year study of the Committee on the Costs of Medical Care, headed by Dr. Ray Lyman Wilbur, Past President of the AMA, and underwritten financially by eight Foundations, had been in progress since early 1928. Several individual studies which would be incorporated in the overall study were being released for publication from time to time.

It soon became evident from the tenor of these reports that the Committee would not be unanimous in its findings. Of the fifty members of the Committee, seventeen were physicians engaged in private practice. The others represented public health, social sciences, the public, and institutional and special interests.

In the Committee's final report, released in 1932, the majority recommended among other things that "both preventive and therapeutic (services) should be furnished largely by organized groups of physicians, dentists, nurses, pharmacists, and other associated personnel, such groups to be organized preferably around the hospital, for rendering complete home, office, and hospital care," and that "the costs of medical care be placed on a group payment basis through the use of insurance, through the use of taxation, or through the use of both these methods."

The principal minority group, representing the viewpoint of private physicians, on the other hand, recommended that Government competition in the practice of medicine be discontinued, that its activities be restricted to the care of the indigent, promotion of public health, support of medical departments of the armed forces, and the provision of medical care to veterans suffering from bona fide service-connected disabilities and disease. There was pointedly no endorsement of voluntary health insurance, although the development of plans for medical care by medical societies was recommended. There were no suggestions offered as to the kind of plans these should be.

Recommendations of both the majority and the minority groups stirred up heated discussions throughout the country and marked the beginning of a controversy which has continued down to the present time.

If any of you have not read the final report of the Committee on the Costs of Medical Care, you should do so, as nearly all the economic issues facing medicine today stem from this document.

There were, at that time, other problems of more immediate concern to physicians in Milwaukee. Agitation had nearly reached a boiling point over contract practice. A large number of physi-

cians in this industrial community had an agreement with some industry, mutual aid society, or fraternal organization. Some of the more agitated physicians who had no contracts insisted that the "rascals" who had them be thrown out of the Medical Society. The situation, which was not peculiar to Milwaukee, finally reached a stage where it seemed that the organization would be split down the middle. Fortunately, the strategy developed by officers of the Medical Society in an effort to heal differences worked.

However, contract practice continued to be an irritation to many physicians, who were very vocal about it. In one instance, lodge practice reached such a low ebb as to quality that even the men who had accepted these arrangements quit in disgust.

Physicians engaged in so-called ancillary services were especially pessimistic about the situation. The President of the Milwaukee County Medical Society, for example, wrote an article entitled, "Can the Pathologists Survive?" He raised the question which one still hears today: "What is there to prevent the pathologist's present position being recognized as a precedent for hospitals' employing surgeons and internists in the same manner in which pathologists and roentgenologists are now employed?"

For some years thereafter, there were scattered flurries of excitement among the profession over these issues, but finally things settled down to a simmer. The Depression had deepened, and the New Deal was in the ascendancy. Unemployment increased rapidly, with the result that at one time in Milwaukee a substantial part of the population was on relief. Many physicians and their patients, therefore, were in financial straits.

On the initiative of the Medical Society county, authorities agreed to pay physicians caring for the medically indigent on a fee basis. It became a far greater undertaking than was anticipated in the beginning and, of course, lasted much longer.

Early in 1933, it became quite apparent to leaders in organized medicine that several signers of the majority report of the Committee on the Costs of Medical Care and their supporters were preparing to implement their recommendations if at all possible. Articles dealing with medical costs were appearing in newspapers and magazines with increasing frequency.

The New Deal Administration announced it would seek the enactment of compulsory health insurance legislation. This was on its list as a must. Organized medicine was equally determined that such legislation should not be enacted. Surprisingly, the Administration did not press the matter too strongly until 1943, when the first Wagner Compulsory Health Insurance Bill was introduced.

Deeply concerned with these developments were a handful of medical leaders who urged not only the endorsement of voluntary health insurance but that something be done to get prepayment plans into operation.

It must be admitted that there was not much enthusiasm for this proposal among the medical profession. One of the most influential medical leaders of that period was the late Dr. Olin West, then Secretary and General Manager of the American Medical Association. Those of us who knew Dr. West held him in highest esteem. He was a man of convictions, integrity, and great courage. It was he who made the statement in the latter 1920's that "one great outstanding problem for the medical profession today is that involved in the delivery of adequate scientific medical service to all the people, rich and poor, at a cost which can be reasonably met by them in their respective stations in life." But Dr. West was no friend of medical society-sponsored voluntary health insurance plans. He was, to put it mildly, opposed to health insurance programs of any kind. I recall discussing the matter with him one time in Chicago. He was vehement in his insistence that voluntary health insurance could only lead to the compulsory variety.

Whether he was correct in his opinion, only time will tell. At any rate, a number of highly regarded physicians at that time disagreed with him, taking the position that a negative stand could not be justified. Leading physicians in such states as Wisconsin, Michigan and California raised their voices in strong support of prepaid medicine on a voluntary basis.

Before the 1930's came to a close, medical society-sponsored prepayment plans had made or were about to make their bow in California and Michigan. Washington State and Oregon had for a number of years a form of prepayment which was quite different from that which came later. Prepayment medicine did not gain real momentum until the 1940's, when Blue Shield came into existence.

These, then, are some of the phases of third

party medicine which occupied the attention of the medical profession until World War II, when discussion of the subject ceased for the duration of the War.

With the passing of the Truman Administration and the election of President Eisenhower, the fire of controversy again died down perceptibly.

GROWTH OF THE THIRD PARTY

What is the situation today? Has the third party withered on the vine, or has it flourished? The answer is obvious to everyone. As I stated in the beginning, it is only too apparent that the third party has gained great momentum, with what effect remains to be seen.

Contract practice, especially as it involves hospitals, is still an issue. Legal proceedings have been instituted in some states to prevent the corporate practice of medicine. In one or two instances these efforts have been successful, the most outstanding being in Iowa.

There is no need to dwell upon the phenomenal growth of voluntary health insurance. Although still in its infancy it is a lusty infant. Dr. Odin W. Anderson, Research Director of the Health Information Foundation, states that in 1957, 40 per cent of the total expenditures for health services was paid for by a third party. One hundred and eighteen million persons now have some form of health insurance. However, most of the present insurance and prepayment plans offer limited protection against the costs of illness.

"The drive for expansion of benefits," Dr. Anderson states, "has proved to be relentless since the costs outside the hospital frequently prove to be unduly burdensome for a family."

Six to 700 insurance companies are writing health insurance. There are about 300 Blue Cross, Blue Shield, and other nonprofit plans in operation. Most of the plans providing medical services permit free choice of physicians among those who agree to participate.

In the minds of a large number of physicians Blue Shield Plans are the big hope for the future where the medical profession is concerned. If proper leadership is given them, and if the medical profession co-operates they are confident of success in meeting the reasonable demands and the needs of the people as regards the payment of their medical bills.

As is well known, not all physicians approve Blue Shield Plans. Some say physicians should not engage in the insurance business and should get out of it as soon as they can. Others resent what they consider dictation of their fees. Still others disapprove disciplinary measures by a committee of their colleagues against participating physicians. By and large, the protestations of these physicians are looked upon by those who favor Blue Shield as growing pains.

Commercial insurance companies came into the voluntary health insurance picture following the lead of medical societies. When it became apparent to the companies that prepayment was not only feasible but could be made sound actuarially they became actively interested.

It is superfluous for me to tell you that labor unions are and will undoubtedly continue to be a formidable factor in third party medicine. They control vast health and welfare funds. This places them in a strategic position. It is apparent that much patience and good will on the part of both labor and the medical profession will be required to arrive at a mutually satisfactory understanding.

Nothing has been said up to this point about local, state, and Federal governments as a third party. Agencies included in this category are public health departments, all of which engage to a considerable extent in both curative and preventive medicine; the Veterans Administration, which not only provides all forms of medical care for veterans through its hospitals but in some states home care rendered by private physicians; and a large number of general and specialty hospitals and other medical institutions which make available medical service to a large segment of the country's population. The Government's Medicare program is the most recent arrival upon the third party scene. As you know, this program provides medical care for dependents of personnel in the uniformed forces under agreements with most state medical societies.

This, of course, is only a partial list of organizations and institutions which can be classified as a third party. It is sufficient, however, for the purpose of this discussion.

WHAT ABOUT THE FUTURE?

Understandably, these developments have deeply concerned many physicians who have grave misgivings about the future of private medical practice. The question uppermost in their minds is: What is the best course for the medical profession to pursue? Is the third party situation the menace

it appears to be? What elements in the third party arrangement are essential to safeguard the best interests of patients and physicians? What should be done to win sympathetic public support for the medical profession's point of view? I have discussed these questions with a number of physicians engaged in private practice for whose judgment I have the highest regard. The following, with slight variations, is a consensus of their views.

They were unanimous on one point—inroads of third party medicine will continue and will expand. As one physician wrote me, "I believe you will agree that there is nothing on the horizon lessening third party activities. I only hope that we will recognize that we have both friends and foes and will consider each case on its merits. To fight the inevitable on general principle is to fight a losing battle."

Of course, this physician said he did not mean that the profession had to accept anything that was handed it. He did mean that there would have to be some pretty objective thinking in the top echelons of organized medicine about the third party issue. First things, he insisted, will have to come first, and where medicine is concerned that is, as it always must be, the welfare of the patient.

Whether the third party is friend or foe in the minds of most physicians depends upon three things: (1) acceptance of the free choice principle, (2) noninterference in professional matters, and (3) adequate compensation, preferably on a fee basis.

The best assurance of maintaining free choice, my medical associates insisted, is for the profession to see to it that the quality of medical service is kept at a uniformly high level. Most physicians with whom I talked believe that much more should be done to assure the people that they need have no concern on this score.

At the present time a licensed physician can do as he likes about keeping abreast of medical progress. He may be, and sometimes is, content with what he learned in medical school and through experience in practice. Hospital medical staffs, however, have done much to maintain high standards of practice, but there is very little supervision of them outside these institutions.

Any mandatory requirement that all licensed physicians meet arbitrary standards of practice would undoubtedly meet with strong opposition by the profession. Nevertheless, this factor in the acceptance of the free choice principle cannot be ignored. The American Academy of General Practice recognized this when it required of its members that each year they do a certain amount of postgraduate study.

Another barrier to acceptance of the free choice principle, according to physicians with whom I have discussed the subject, is failure of medical organizations to take effective disciplinary action against wayward members. Grievance committees, in most instances, they say, are soft cautious, or ineffectual. However, they admit there are a number of exceptions. The State of Washington now has a Medical Disciplinary Law which is being watched with considerable interest by the medical leaders.

The most prized prerogative of a physician is his freedom to exercise his professional judgment without interference. This is something that medicine has fought for with unyielding vigor. It is vitally important to patients as well as to physicians.

There is no question in the minds of students of the subject that in a decade or less voluntary insurance plans, if they are still in existence, will have enjoyed tremendous growth and provide much greater coverage than they now do. In fact, it is certain that most of the people in this country, probably 90 per cent of the population, will be protected by health insurance in some form. This means, of course, that the third party will be largely responsible for their medical bills. Fee schedules or specified payments for various procedures will of necessity have been accepted by the medical profession.

If this situation should come to pass, how satisfactory will the medical profession find it? That depends on how alert they have been and the leadership they have shown. One would think, with all the discussion, all the articles, and all the books that have been written on the socioeconomic aspects of medicine, that much of it would have permeated the doctor's thinking. On the contrary, it is surprising how few are informed, or are very interested in this subject. Happily, there is a group of whom this is not true. They are the ones on which many of us are pinning our hopes.

It is well known that socioeconomic patterns adopted nationally are never abandoned. One can be certain, for example, that Social Security is here to stay. So is contract practice. So is volun-

tary health insurance. In this situation it is vital that organized medicine provide constructive leadership.

Whether the third party is a friend or foe then depends a great deal upon medical leadership. This is especially true where the voluntary health insurance plans are concerned. The medical profession needs to know more about these plans and those who administer them. Without question, they are organized medicine's most valuable instrument in dealing with medical costs.

A few weeks ago Dr. Edward J. Stieglitz, a nationally known authority on the aging and a member of our Medical Society, submitted an article for publication in our medical journal entitled, "Water." In this article he stated he could not recall water being ever mentioned in scientific journals as a nutritional element.

"This blind spot," he wrote, "has often reminded me of the anecdote about the barfly who said to the bartender that blindfolded he could identify all ingredients in any mixed drink which the bartender could concoct. If he failed, he would pay double for the drink, but if he succeeded, he would get it free. The bartender mixed one cocktail after another. The contents of each was identified with unfailing accuracy. In desperation, the bartender presented the man with an educated palate with a glass of water. The man tasted it carefully, rolled it about in his mouth, tried another sip, but was obviously puzzled. Finally he said, 'I don't know what this is, but I am sure it won't sell.' "

If the facts presented and the views here expressed are unacceptable to you, I have made no "sale." On the other hand, if what I have said has opened up some new channels of thought on controversial issues, it will not have been time wasted for any of us.

THEODORE WIPRUD

Mr. Wiprud is Executive Director and Secretary of the Medical Society of the District of Columbia.

A RESOLUTION CONCERNING THE PRACTICE OF PATHOLOGY IN MINNESOTA

1. WHEREAS, the honored ideals of the medical profession are designed to render the best possible service to the patient and to society through planned direction and the practice of most modern medical care, in the continuous struggle against deterioration, suffering and the disease of mankind, and

2. WHEREAS, the natural history of the development of laboratory medicine over a half century has been from the very few and simple procedures needing but little medical guidance to the numerous and complex modern highly efficacious procedures requiring a special medical training for their proper execution, and

3. WHEREAS, the early limited usages and slow advances in pathology in the hospital laboratories resulted in an early acceptance of the responsibility of laboratory medicine by lay administrators and Boards of Directors of hospitals, and

4. WHEREAS, the wisdom of the original State laws and subsequent rulings of the State Supreme Court concerning the practice of even the simplest laboratory procedure under the direct and complete control of trained physicians of Medicine has now reached a pinnacle of acknowledgment by those most likely to know, i.e., the licensed physicians of the State, and

5. WHEREAS, the physicians of the country have repeatedly studied these problems and have stated in 1943 that, "The House of Delegates of the American Medical Association is opposed to the division of any branch of medical practice into so-called technical and professional factions," and later, in 1951, that, "The practice of anesthesiology, pathology, physical medicine, and radiology are an integral part of the practice of medicine in the same category as the practice of surgery, internal medicine or any other designated field of medicine, and in 1955 re-affirmed its position on these matters and in 1958 the House of Delegates of the Minnesota State Medical Society stated in part that it "officially recognizes the specialty of Anatomical and Clinical Pathology as the practice of medicine; reaffirms the philosophy that in-hospital and out-patient diagnostic laboratory services are in fact the practice of medicine, and in future contracts or actions relating to laboratory medicine actively reaffirms the belief in the legal control of all medical laboratory facilities in the State of Minnesota by licensed doctors of medicine," and

6. WHEREAS, the present-day control of the medical specialty of Clinical and Anatomical Pathology in most of the hospitals in Minnesota by lay corporations, eleemosynary or otherwise, has placed an ever-increasing restraint and interference upon the scientific advancements in Pathology to the great detriment of the patients and the public; therefore

BE IT RESOLVED, that the Minnesota Society of Clinical Pathologists requests the concerted effort of the Minnesota State Medical Association to (1) bring all laboratory medicine under Minnesota Medical Service Contracts, and (2) as soon as possible eliminate the controlling role of the non-medical, third party in the practice of Pathology in all of the non-governmental hospitals of Minnesota.

Approved by: MINNESOTA SOCIETY OF CLINICAL PATHOLOGISTS

President's Letter

SEE YOU IN DULUTH!

Spring is here and soon we shall be hearing, on radio and television, the old familiar strain, "Take Me Out to the Ball Game." It will also mean that the 106th Annual Meeting of the Minnesota State Medical Association is not far away. The meeting this year will be held at Duluth, Minnesota, the "air-conditioned city" at the head of the St. Lawrence Seaway, on May 25, 26, and 27, 1959.

Your committee on Scientific Assembly has been working diligently, and the program is ready to go to press. The Monday morning (May 25) session will lead off with "What's New in Cardiovascular Disease." This panel, sponsored by the Minnesota Heart Association, will be moderated by Dr. F. J. Hirschboeck of Duluth. The panel will consist of Henry I. Russek, M.D., New York City; James W. Culbertson, M.D., formerly with University Hospitals, Iowa City, now in Memphis, Tennessee, and John W. Kirklin, M.D., Rochester, Minnesota. This, I am sure will be high class.

The cardiac panel will be followed by the Russell D. Carman Lecture—delivered by James E. Lofstrom, M.D., Professor of Radiology, Wayne University, Detroit, Michigan. Soon to follow will be a discussion by Paul Medelman, M.D., and John Briggs, M.D., on "Routine Hospital Admission X-Rays and other Tuberculosis Control Measures."

On Monday afternoon, there will be a Symposium on Breast Cancer, moderated by F. W. Lynch, M.D., Professor of Dermatology, University of Minnesota. C. D. Haagensen, M.D., New York City, sponsored by the American Cancer Society, will be the guest speaker on "Surgery." B. J. Kennedy, M.D. and Donn Mosser, M.D., from the University of Minnesota, will speak on "Chemotherapy" and "Radiation Therapy," respectively. At 4:00 p.m., Monday, Ian Brown, M.D., Neurologist, St. Paul, Minnesota, will conduct an interesting panel on "Management of Strokes." Dr. Brown will be assisted by Glenn Gullickson, M.D., Psychiatrist, University of Minnesota, Davitt A. Felder, M.D., St. Paul, Vascular Surgeon, and Dr. Shirley Holt Mink, Minneapolis, a certified Psychologist.

Tuesday, May 26, R. S. Ylvisaker, M.D., Minneapolis, will moderate a Symposium on Massive Gastro-Intestinal Bleeding. Assisting Dr. Ylvisaker will be E. E. Wollaeger, M.D., Rochester; R. B. Tregilgas, M.D., St. Paul; Lyle Hay, M.D., Minneapolis, and Owen McDonald, M.D., Duluth.

John E. Harris, M.D., Head of Department of Ophthalmology, University of Minnesota, will present the Academy of Ophthalmology Lecture on "Use of Steroids in Ocular Disease."

A highlight of the meeting will be E. T. Bell, M.D., Minneapolis, who will present the Arthur H. Sanford Lecture. His title will be "A Clinical and Pathological Comparison of Chronic Glomerulonephritis and Malignant Hypertension."

At 2:00 p.m., Tuesday, there will be a Symposium on Urological Problems in Children, moderated by T. H. Sweetser, Jr., M.D., Minneapolis. Assisting will be C. A. Linke, M.D., Duluth, on "Urinary Tract Infections," and Cornelius Vermeulen, M.D., University of Chicago, on "Formation of Stones."

Moses Barron, M.D., Minneapolis, will conclude the Tuesday program, speaking on "The Current Status of Oral Hypoglycemic Agents."

Wednesday, R. N. Bieter, M.D., Head of Pharmacology, University of Minnesota, will speak on "New Drugs and Insecticides." Following Doctor Bieter, the Academy of General Practitioners are sponsoring W. B. Hildebrand, M.D., President of the State Medical Society of Wisconsin, who will speak on the "Relationship of the General Practitioner to the Specialist."

"Accidents in Children—The No. I Killer," will be the title that Tague Chisholm, M.D., Minneapolis, will use for his Wednesday morning presentation.

Later on Wednesday, "Animal Diseases Transmissible to Man" will be presented by Robert J. Anderson, Assistant Surgeon General, Chief Communicable Disease Center, Atlanta, Georgia. The Northwestern Pediatric Society Lecture will be given by Theodore C. Panos, Professor and Chairman, Department of Pediatrics, University of Arkansas, Little Rock, Arkansas.

The grand finale will be a Symposium on Staphylococcus Infections, moderated by Wesley Spink, M.D., University of Minnesota. Assisting in presenting this most important present-day subject will be Claude R. Hitchcock, M.D., Minneapolis; Robert I. Wise, M.D., Jefferson Medical College, Philadelphia, and Arthur H. Wells, M.D., Duluth.

The Annual Banquet will be held in the Ballroom of the Hotel Duluth at 7:00 p.m. on Tuesday, May 26. You will note that this year's speaker selection will mark a change of pace. We have indeed been fortunate to secure for this occasion, Dr. E. W. Ziebarth, Dean, Summer Session, University of Minnesota. "Russia Today" will be discussed by Dr. Ziebarth in his banquet address.

Benjamin B. Sweetser M.D.

President, Minnesota State Medical Association

Minnesota State Medical Association

106th Annual Meeting

Duluth, Minnesota—May 25-27, 1959

Preliminary Program

BUSINESS SESSIONS

Hotel Duluth

SATURDAY, MAY 23

2:00 P.M.—Council
English Room, Hotel Duluth
6:00 P.M.—Council Dinner
Parlor A, Hotel Duluth
8:00 P.M.—Council
English Room, Hotel Duluth

SUNDAY, MAY 24

8:30 A.M.—Council
English Room, Hotel Duluth
10:00 A.M.—Reference Committees
Rooms to be assigned
2:00 P.M.—House of Delegates
Ballroom, Hotel Duluth
6:00 P.M.—New Members and County Officers Dinner
Moorish Room, Hotel Duluth
8:00 P.M.—House of Delegates
Ballroom, Hotel Duluth

MONDAY, MAY 25

8:30 A.M.—Council
English Room, Hotel Duluth
12:15 P.M.—House of Delegates
Ballroom, Hotel Duluth

TUESDAY, MAY 26

8:00 A.M.—Committee Breakfasts
Rooms to be assigned
8:30 A.M.—Council
English Room, Hotel Duluth

WEDNESDAY, MAY 27

8:00 A.M.—Committee Breakfasts
Rooms to be assigned
8:30 A.M.—Council

SOCIAL EVENTS

SUNDAY, MAY 24

Golf Buffet and Cocktails

5:00 p.m. Northland Country Club

Dinner

New Members and County Officers Dinner
6:00 p.m. Moorish Room, Hotel Duluth

MONDAY, MAY 25

Dinners

Minnesota Academy of General Practice
6:00 p.m. Hotel Duluth. Tickets, $6.00, gratuity included.
Speaker: Miss Ann Landers, newspaper columnist, Chicago Sun Times Syndicate

Minnesota State Radiological Society
6:00 p.m. Dinner and Annual Meeting, Northland Country Club.
Speakers: J. E. Lofstrom, Detroit, Michigan, and Mr. Robert Morrison, Eastman Kodak Company

Open House

Minnesota State Medical Association
9:00 p.m. Ballroom, Hotel Duluth.
All physicians and their wives are invited to attend OPEN HOUSE as guests of the St. Louis County Medical Society.

TUESDAY, MAY 26

Luncheons

Minnesota Academy of Ophthalmology and Oto-Laryngology
12:30 p.m. Kitchi Gammi Club, Duluth. John E. Harris will speak on "Complications of Systemic Steroid Therapy."

Minnesota Society of Clinical Pathologists
12:15 p.m. Kitchi Gammi Club, Duluth

Medical Women's Association
12:30 p.m. Kitchi Gammi Club, Duluth. A special luncheon meeting has been planned for women physicians by the Alpha Epsilon Iota Medical Sorority. Two students in the Foreign Exchange Program will tell of their experiences—Sally McDonald in Europe and Dale Coventry in South America. Luncheon tickets are $2.50. Send reservations and checks to Dr. Elizabeth Bagley at 2306 East Superior Street, Duluth 5, Minnesota.

Dinners

Minnesota Society of Clinical Pathologists
6:30 p.m. Annual Dinner and Business Meeting, Duluth Athletic Club.

Minnesota State Medical Association
7:00 p.m. Annual Banquet, Ballroom, Hotel Duluth. Tickets are $6.00, gratuity included.
Speaker: Dr. E. W. Ziebarth, Dean, Summer Session, University of Minnesota.
Introduction of Woman's Auxiliary President: Mrs. M. F. Fellows, Duluth.
Presentations:
Fifty Club Certificates
Southern Minnesota Medical Association Medal
Distinguished Service Medal

WEDNESDAY, MAY 27

Luncheon

American Academy of Pediatrics, Minnesota Chapter
12:15 p.m. Luncheon at the Northland Country Club.

ROUND TABLES

Hotel Duluth—12:15 P.M.

MONDAY, MAY 25

Maternal Mortality Studies
Arranged by J. J. SWENDSON, Chairman of Committee on Maternal Health

Factors Responsible for the High Incidence of Clinical Coronary Atherosclerosis in the United States
HENRY I. RUSSEK, New York City

Present Day Knowledge of the Etiology of Some Common Types of Cancer
C. D. HAAGENSEN, New York City

TUESDAY, MAY 26

Immunization—Current Status
CAPTAIN J. R. KINGSTON, U.S. Navy, Washington, D. C., and others.

Thoracic Injuries
JOSIAH FULLER, Duluth

Automobile Injuries
MR. JOHN O. MOORE, Cornell University

Medical Farm Hazards—Silo Filler's Disease and Farmer's Lung
C. H. HODGSON, Rochester

Evaluation of Newer Hypertensive Drugs
JOHN G. FEE, St. Paul

Physiologic Variations in Body Fluids and Cellular Components—Practical Aspects
ELLIS S. BENSON, Minneapolis

Treatment of Blunt Trauma in the Abdomen
HOWARD R. SNIDER, Mankato

Shock Therapy
RICHARD C. LILLEHEI, Minneapolis

Obstructive Hearing Loss in Childen
J. D. SJODING, Mankato

WEDNESDAY, MAY 27

Oral Polio Vaccine
MAURICIO MARTINS DA SILVA, Washington, D. C.
HERALD COX, Pearl River, New York

Medical-Legal Evaluation of Traumatic Disabilities
S. S. HOUKOM, Duluth

Thyroiditis
A. W. SHEA, BERTON D. MITCHELL, Minneapolis

Work Evaluation in Heart Disease
ARTHUR C. KERKHOF, Minneapolis

New Antibiotic Drugs
ROBERT I. WISE, Philadelphia
WESLEY W. SPINK, Minneapolis

Inhalation Therapy
ALBERT H. ANDREWS, Chicago, Illinois

Nephrosis in Children
THEODORE C. PANOS, Little Rock, Arkansas

X-Ray Clinical Conference
JOSEPH J. ASTA, Duluth

Medical Functions of County Coroners
RAYMOND N. BEITER, St. Paul
JOHN I. COE, Minneapolis

Ocular Injuries and Emergencies
JOHN E. HARRIS, Minneapolis

GENERAL SESSION

Duluth Armory

MONDAY, MAY 25

Morning Session

Chairman: L. M. HAMMAR

A.M.
8:30 Visit Scientific and Technical Exhibits

9:00 WHAT'S NEW IN CARDIOVASCULAR DISEASE—Panel Discussion
Moderator, F. J. HIRSCHBOECK, Duluth
HENRY I. RUSSEK, Consultant in Cardiovascular Research, U. S. Public Health Service Hospital, Staten Island, N. Y.
JAMES W. CULBERTSON, Professor of Medicine, College of Medicine, University of Tennessee, Memphis, Tennessee
JOHN W. KIRKLIN, Rochester

10:15 INTERMISSION
Visit Scientific and Technical Exhibits

11:00 RUSSELL D. CARMAN MEMORIAL LECTURE
Breakthroughs in the Solution of the Stroke Problem
JAMES E. LOFSTROM, Chairman-Professor, Division of Radiology, Wayne State University, Detroit, Michigan

11:30 ROUTINE HOSPITAL ADMISSION X-RAYS AND OTHER TUBERCULOSIS CONTROL MEASURES
JOHN F. BRIGGS, St. Paul
Discussion:
J. P. MEDELMAN, St. Paul

Afternoon Session

Chairman: J. E. TWOMEY

P.M.
12:15 Round Table Luncheons

1:30 Visit Scientific and Technical Exhibits

2:00 SYMPOSIUM ON BREAST CANCER
Moderator, F. W. LYNCH, St. Paul
Surgery
CUSHMAN D. HAAGENSEN, Professor of Surgery, Columbia University, New York City. *Sponsored by Minnesota Division, American Cancer Society*
Chemotherapy
B. J. KENNEDY, Minneapolis
Radiation Therapy
DONN MOSSER, Minneapolis

3:15 INTERMISSION

4:00 MANAGEMENT OF STROKES—Panel Discussion
Moderator, IAN A. BROWN, St. Paul
Neurological Aspects
IAN A. BROWN, St. Paul
Physical Rehabilitation
GLENN GULLICKSON, Minneapolis
Vascular Surgery
DAVITT A. FELDER, St. Paul
Arteriography
JAMES E. LOFSTROM, Detroit, Michigan
Psychological Aspects
SHIRLEY HOLT MINK, PH.D., Minneapolis

GENERAL SESSION
Duluth Armory

TUESDAY, MAY 26

Morning Session

Chairman: WILLIAM D. COVENTRY

A.M.

8:30 Visit Scientific and Technical Exhibits

9:00 SYMPOSIUM ON MASSIVE GASTRO-INTESTINAL BLEEDING
Moderator, R. S. YLVISAKER, Minneapolis
Causes and Diagnosis
E. E. WOLLAEGER, Rochester
Medical Management
R. B. TREGILGAS, St. Paul
Indications for Surgery, Emergency and Delayed
LYLE J. HAY, Minneapolis
Types of Surgical Intervention
OWEN MCDONALD, Duluth

10:15 INTERMISSION

11:00 MINNESOTA ACADEMY OF OPHTHALMOLOGY AND OTO-LARYNGOLOGY LECTURE
Use of Steroids in Ocular Disease
JOHN E. HARRIS, Professor and Head, Department of Ophthalmology, University of Minnesota Medical School

11:30 ARTHUR H. SANFORD LECTURE IN CLINICAL PATHOLOGY
A Clinical and Pathological Comparison of Chronic Glomerulonephritis and Malignant Hypertension
ELEXIOUS T. BELL, Minneapolis

Afternoon Session

Chairman: FREDERICK M. OWENS, JR.

P.M.

12:15 Round Table Luncheons

1:30 Visit Scientific and Technical Exhibits

2:00 SYMPOSIUM ON UROLOGICAL PROBLEMS
Moderator, T. H. SWEETSER, JR., Minneapolis
Urology in Children
T. H. SWEETSER, JR., Minneapolis
Urinary Tract Infections
C. A. LINKE, Duluth
Formation of Stones
CORNELIUS W. VERMEULEN, Professor of Surgery (Urology), University of Chicago

3:15 INTERMISSION

4:00 MINNESOTA MEDICAL FOUNDATION LECTURE
Streptococcal Infections and Their Complications
LEWIS W. WANNAMAKER, American Heart Association Career Investigator and Professor of Pediatrics, University of Minnesota

4:30 CURRENT STATUS OF THE ORAL HYPOGLYCEMIC AGENTS
MOSES BARRON, Minneapolis

7:00 Annual Banquet—Ballroom, Hotel Duluth
Presiding: B. B. SOUSTER, St. Paul, President, Minnesota State Medical Association
Introduction of Woman's Auxiliary President: MRS. M. F. FELLOWS, Duluth
Presentations:
Fifty Club Certificates
Southern Minnesota Medical Association Medal
Distinguished Service Award
Russia Today
DR. E. W. ZIEBARTH, Dean, Summer Session, University of Minnesota

GENERAL SESSION
Duluth Armory

WEDNESDAY, MAY 27

Morning Session

Chairman: ROBERT N. BARR

A.M.

8:30 Visit Scientific and Technical Exhibits

9:00 New Drugs and Insecticides
R. N. BIETER, Minneapolis

9:30 Relationship of the General Practitioner to the Specialist
W. B. HILDEBRAND, President of the State Medical Society of Wisconsin, and Past President, American Academy of General Practice, Menasha, Wisconsin

10:00 Accidents in Children—The No. 1 Killer
TAGUE C. CHISHOLM, Minneapolis

10:15 INTERMISSION

11:00 Animal Diseases Transmissible to Man
ROBERT J. ANDERSON, Assistant Surgeon General and Chief, Communicable Disease Center, Department of Health, Education and Welfare, Atlanta, Georgia
Discussion: ROBERT K. ANDERSON, D.V.M., St. Paul

11:30 NORTHWESTERN PEDIATRIC SOCIETY LECTURE
Nutritional Requirements of the Neonate
THEODORE C. PANOS, Professor and Chairman, Department of Pediatrics, University of Arkansas, Little Rock, Arkansas

Afternoon Session

Chairman: ARTHUR M. OLSEN

P.M.

12:15 Round Table Luncheons

1:30 Visit Scientific and Technical Exhibits

2:00 SYMPOSIUM ON STAPHYLOCOCCUS INFECTIONS
Moderator, WESLEY W. SPINK, Minneapolis
Surgical Infections
CLAUDE R. HITCHCOCK, Minneapolis
Control of Hospital Infections
A. H. WELLS, Duluth
Resistance and Therapy
ROBERT I. WISE, Magee Professor of Medicine, Head of Department of Medicine, The Jefferson Medical College of Philadelphia

Woman's Auxiliary

37th Annual Meeting

PROGRAM

MONDAY, MAY 25

A.M.
9:00 Registration.....Mezzanine, Hotel Duluth
10:30 Executive Board Meeting....Kitchi Gammi Club
P.M.
1:00 Executive Board Luncheon..Kitchi Gammi Club
Tickets $2.25
3:00 Tea.....Tweed Art Gallery—U.M.D. Campus
Cars leave front entrance of Hotel Duluth for Tweed Art Gallery, 2:45-4:00 P.M. All visiting women are cordially invited to be guests of the St. Louis County Medical Auxiliary. (Through courtesy of the Art Department of the University of Minesota, Duluth Branch.)
9:00 Open House.....Ballroom, Hotel Duluth

TUESDAY, MAY 26

A.M.
9:00 Registration.....Mezzanine, Hotel Duluth
9:30 Annual Meeting
Arrowhead Room, Hotel Duluth
Open to ALL members of the Auxiliary.
Presiding—Mrs. Reuben F. Erickson, President, Minneapolis
Pledge of Allegiance—Mrs. William Finkelnburg, Winona
Auxiliary Pledge—Mrs. John W. Stuhr, Stillwater
"I pledge my loyalty and devotion to the Woman's Auxiliary to the American Medical Association. I will support its activities, protect its reputation and ever sustain its high ideals."
Address of Welcome—Mrs. Gordon Strewler, Duluth, President, St. Louis County Medical Auxiliary
Response—Mrs. Rodney Sturley, St. Paul
Presentation of Convention Chairman—Mrs. M. O. Wallace and Mrs. I. T. Clark, Duluth
In Memoriam Service—Mrs. A. M. Jensen, Brownton
Music: Violinist—Mrs. A. C. Hilding, Duluth
Reports
Election of Officers
P.M.
1:00 Annual Luncheon.....Ballroom, Hotel Duluth
Tickets $2.50
"The Physician's Wife — Generalist" — Mrs. Aaron Margulis, Santa Fe, New Mexico, National Committee Chairman on Mental Health.
"What the Seaway Will Mean to Minnesota"—Mr. Eugene R. Lambert, Former Mayor of Duluth
Installation of Officers—Mrs. H. H. Fesler, St. Paul
Installation of President and Presentation of President's Pin—Mrs. H. E. Bakkila, Duluth
Presentation of Gavel
Greetings from the New President—Mrs. M. F. Fellows, Duluth
Post-Convention Board Meeting
English Room, Hotel Duluth
7:00 Annual Banquet.....Ballroom, Hotel Duluth
Presiding—B. B. Souster, President, Minnesota State Medical Association
Introduction of Woman's Auxiliary President:
Mrs. M. F. Fellows, Duluth
Presentations:
Fifty Club Certificates
Southern Minnesota Medical Association Medal
Distinguished Service Award
"Russia Today"—Dr. E. W. Ziebarth, Dean, Summer Session, University of Minnesota

WEDNESDAY, MAY 27

A.M.
10:30: "Round-up Breakfast"....Duluth Women's Club
Tickets $1.50

Committees

General Arrangements—Mrs. M. O. Wallace, Chairman, and Mrs. I. T. Clark, Co-Chairman.

Reservations—Mrs. C. H. Christensen, Chairman.

Tickets—Mrs. Harry Klein, Chairman, and Mrs. William Swedberg, Co-Chairman.

Hospitality—Mrs. H. E. Bakkila, Chairman; Mrs. A. J. Bianco, Co-Chairman; Mrs. M. F. Fellows, Mrs. Joseph Bloom, Mrs. G. J. Strewler, Mrs. J. K. Butler, Mrs. J. E. Haavik, Mrs. F. J. Elias, Mrs. J. J. Asta, Mrs. V. A. Harrington, Mrs. Richard Bardon, Mrs. K. E. Johnson, Mrs. J. D. Barker, Mrs. F. H. Magney, Mrs. E. E. Barrett, Mrs. W. B. Martin, Mrs. R. T. Kelly, Mrs B. T. French, Mrs. B. Halper.

Transportation—Mrs. R. E. Nutting, Chairman; Mrs. P. S. Rudie, Co-Chairman; Mrs. H. G. Moehring, Mrs. J. L. Tuura, Mrs. H. J. Walder, Mrs. W. H. Grohs, Mrs. R. O. Bergan, Mrs. R. C. Pedersen, Mrs. A. W. Pasek, Mrs. A. E. Reardon.

Registration—Mrs. F. W. Conley, Chairman; Mrs. J. H. Peterson, Co-Chairman; Mrs. P. H. Marrone, Mrs. L. R. Gowan, Mrs. J. F. Schmid, Mrs. N. E. Tosseland, Mrs. A. E. Olson, Mrs. V. R. Krueger, Mrs. B. J. Terrell, Mrs. J. R. Chittum, Mrs. W. H. Parker, Mrs. K. E. Ahola.

Tea—Mrs. A. O. Swenson, Chairman; Mrs. S. N. Litman, Co-Chairman: Mrs. J. F. Schmid, Mrs. Henry Fisketti, Mrs. J. J. Dwyer, Mrs. B. J. Terrell, Mrs. J. H. Peterson, Mrs. George Cowan, Mrs. William A. Klein, Mrs. William B. Martin, Mrs. V. R. Krueger, Mrs. K. E. Johnson, Mrs. W. G. Strobel, Mrs. E. E. Barrett, Mrs. R. R. Juntunen.

Music—Mrs. A. C. Hilding, Chairman; Mrs. K. R. Fawcett, Mrs. J. P. Tetlie.

Executive Board Meeting and Luncheon—Mrs. J. E. Haavik, Chairman, and Mrs. R. O. Bergan, Co-Chairman.

Annual Meeting and Luncheon—Mrs. J. B. Moyer, Chairman; Mrs. J. C. Feuling, Co-Chairman: Mrs. M. M. Fifield, Mrs. K. A. Storsteen, Mrs. K. E. Latterell, Mrs. F. H. Dickson.

Flowers—Mrs. F .C. Jacobson, Chairman; Mrs. William Swedberg, Co-Chairman; Mrs. H. J. Jeronimus, Mrs. J. C. Feuling, Mrs. A. I. Balmer, Mrs. A. E. Olson, Mrs. Paul Van Puffelen, Mrs. J. M. Wolff, Mrs. C. F. Ahrens, Mrs. Chester Lund, Mrs. P. V. Halliday, Mrs. W. S. Pollard.

Pages—Mrs. A. L. Abraham, Chairman; Mrs. E. I. Parson, Co-Chairman: Mrs. Paul Van Puffelen, Mrs. Roy Pedersen, Mrs. Albert Balmer, Mrs. Robert Goldish.

Breakfast—Mrs. M. G. Gillespie, Chairman; Mrs. J. K. Butler, Co-Chairman; Mrs. J. J. Coll, Mrs. H. J. Walder, Mrs. G. C. MacRae.

Publicity—Mrs. I. V. Thomas, Chairman, and Mrs. J. C. Trautmann, Co-Chairman.

Exhibits—Mrs. K. E. Latterell, Chairman, and Mrs. O. G. McDonald, Co-Chairman.

George Earl, M.D., Chairman

AMERICAN MEDICINE-BLUE SHIELD PARTNERSHIP URGED

More than 300 people, half of whom were physician trustees representing Blue Shield Plan governing boards and officers of twenty state medical societies, attended the annual Blue Shield National Professional Relations Conference held in Chicago, February 9-11. The executive secretaries of some twenty-five state and county societies and 130 Blue Shield Professional Relations personnel comprised the balance of the conference group.

Minnesotans Present

Minnesotans attending included: B. B. Souster, M.D., President of the Minnesota State Medical Association, and J. P. Medelman, M.D., Councilor for the Fifth District. Minnesota Blue Shield representatives attending the conference were: R. R. Cranmer, M.D., President, Board of Directors, Minnesota Blue Shield; W. W. Yaeger, M.D., Board of Directors; P. G. Hoeper, M.D., Board of Directors; C. W. Moberg, M.D., Board of Directors; C. A. McKinlay, Board of Directors and Secretary; and E. C. Bayley, M.D., Board of Directors and Treasurer.

AMA President-Elect Commends Blue Shield

Dr. Louis M. Orr, of Orlando, Florida, President-Elect of the American Medical Association, in a keynote address commended Blue Shield for its "magnificent role" in developing the medical prepayment program, and urged "all members of the health team" to "recapture the pioneering spirit which was the foundation on which Blue Cross and Blue Shield were built."

"Let's stand together and stand united against the thrusts of big government into the medical care field," Dr. Orr urged. "And equally important, let's step up the current vigorous program to provide realistic positive approaches to all phases of health care among all people, young or old."

Referring directly to the needs of "senior citizens," Dr. Orr said he was "gratified that Blue Shield has been one of the first to pledge its all-out cooperation in working with the medical profession to do an effective job in providing medical care for the aged, especially the lower income group." He also commended Blue Shield's present accomplishments in developing a model contract for people over sixty-five, and progress in removing age limits on non-group enrollment.

Calling for an ever greater effort in this area, Dr. Orr said:

"The future of medicine and voluntary enterprise may well be determined largely by the extent to which Blue Shield and other voluntary financing mechanisms expand their coverage of the older citizens."

Dangers in "Social Security" Medical Care Cited

Dr. Orr further emphasized:

"For the first time in history, legislation of the For- and type would add health benefits to a Social Security program that now pays cash benefits based on the 'floor of protection' concept. This new principle would completely alter the nature of the program, and would open the door for evolution of a system of tax-paid health care for the entire nation. Indeed, it would establish the principle that provision of medical care for any segment of the population, or all of it, is a federal function."

The present Social Security program is expected to cost seven times as much in 1969 as it cost in 1937. This experience "plus the revealing stories of government medicine in European nations, is evidence enough that the initial tax for so-called 'free' medical care will be just a drop in the bucket compared to what will be required in ten or twenty years."

Better Blue Shield-Physician Understanding Needed

Another speaker before the conference was Dr. Donald Stubbs, Washington, D. C., Chairman of the Board of Directors of Blue Shield Medical Care Plans. Dr. Stubbs emphasized the urgent need of better understanding by all physicians of the job that Blue Shield was created to do.

"We've passed the point of no return in building voluntary health insurance in America," he said. "Without Blue Shield, the freedom of medicine would be lost. Blue Shield and the American doctor are identical

in their basic purposes. Medicine seeks to relieve human suffering, while Blue Shield stands for service at the fiscal level. For the doctor, Blue Shield represents a balance of his ethical ideals with the fiscal needs both of his patient and himself. Medicine has come to grips with the economy of our modern world through Blue Shield."

Blue Shield a Community Movement

Dr. Leland S. McKittrick, Boston, Chairman of the AMA Council on Medical Education and Hospitals, emphasized that Blue Shield must be recognized both by the profession and the public as a community movement. "We must have leadership in medicine that is imaginative, yet based on a complete understanding of the problems we are trying to solve," he said.

In his address concluding the conference, Dr. Frank L. Feierabend, Kansas City, President-Elect of Blue Shield Medical Care Plans, stressed that "Blue Shield must be a continuing answer to a continuing problem," and he appealed to the profession to "take the initiative, accept its responsibilities, and exert the leadership that the American people expect of their doctors."

Dr. Feierabend emphasized the need for Blue Shield to constantly improve its service to the public. This can be done only through the leadership of the medical profession.

He warned:

"Socio-economic chaos will result if Blue Cross and Blue Shield were to fail, and drastic changes in medical practice would follow if the voluntary nonprofit Plans fall short of the job they have to do.

"We must have a plan that will provide medical care to at least 75 per cent of the public either on a complete service basis, or on a cash indemnity basis which is accepted on the service principle by the medical profession."

Whenever medical care has been taken over by the State, Dr. Feierabend said, "money was the common denominator which governed the service received by the public." This has been shown in the English system, and again in the United States by our experience with Medicare.

Professional Relations Improvement Discussed

Discussion groups of physician trustees, medical society executives and professional relations personnel of Blue Shield Plans concentrated their attention on ways and means of improving professional relations between the Plans and their sponsoring medical groups, and of, getting the story of Blue Shield across to all the physicians.

These discussions covered the methods of maintaining liaison; ways of involving physicians in the guidance of their Plans; helping doctors to play a leading role in the constant improvement of Blue Shield, so it can meet the needs of patients more completely; the necessity for medicine itself to lead in developing policy, formulating schedules of medical payments, levels of income for service benefits, et cetera; and the importance of the individual doctor understanding the dynamics of Blue Shield and helping to conserve Plan resources as well as utilizing them most fully for the patient's benefit.

The discussion group of Plan professional relations personnel reported an emphatic agreement that *physicians,* individually and collectively, are the key to the success or failure of Blue Shield.

Texas Program Explained

C. Lincoln Williston, Executive Secretary of the Texas Medical Association, told the discussion group that Texas has developed a nineteen-point program of professional relations for Blue Shield, with the leadership being exerted by the Texas State Medical Association. The three objectives of the program are: (1) more effective liaison between the State Society and the Blue Shield Plan; (2) better understanding of Blue Shield by the 8,000 doctor-members of the State Society; (3) to implant the conviction that Blue Shield is the doctors' program.

In a word, the objective is "education; informing physician of existing problems, and securing their wholehearted cooperation in correcting them."

"We believe we have an effective portfolio of communication between Blue Shield and the Texas Medical Association."

Some elements of the program are: Medical Student Day program at three medical schools; Blue Shield as part of Orientation Program, mandatory for all new members; Representation of Blue Shield at all meetings sponsored by the State Society; Speakers for Blue Shield at annual PR Conference and Conference of County Society officials; Assistance to Blue Shield in presenting its story at each county society; Blue Shield news and reports in every issue of the state society journal—also editorials; Blue Shield advertisements in state journal; Publication by Blue Shield of a Membership Directory of Texas physicians; Promotion of Blue Shield enrollment through phy-

sicians; Encouragement of doctors to control overuse of Blue Shield services.

Michigan Committed to Modernized Concept of Medical Care Coverage

Relating the two-year history of the development of Michigan's new Blue Shield program, Max Lichter, M.D., Chairman of the Medical Care Insurance Committee of Michigan State Medical Society, pointed out that the Medical Society's action was guided by an intensive survey of public and medical opinion, which showed, among other things, that people are willing to pay a reasonably increased rate for additional benefits.

The Medical Society "committed itself to a modernized concept of medical care coverage. Michigan Blue Shield accepted the challenge"—and immediately developed a program along the lines requested by the Society.

COMMISSION ON MEDICAL CARE PLANS—UNFINISHED BUSINESS

A committee of the Minnesota State Medical Association has agreed to recommend that the report for the Study of Medical Care Plans of the American Medical Association presented at the recent AMA Clinical Session held in Minneapolis in December, 1958, be accepted, but emphasized the importance of the principle of free choice of physician.

At that meeting, the AMA House of Delegates decided to defer action on the report of the Commission on Medical Care Plans until the June, 1959, meeting in Atlantic City, New Jersey. However, the following statement was adopted by the AMA House of Delegates members.

We respectfully suggest to the constituent associations reviewing the report in the interim, that their attitude regarding the report will be clarified if they arrive at some decisions in regard to the following basic points:

1. *Free Choice of Physician*—Acknowledging the importance of free choice of physician, is this concept to be considered a fundamental principle, incontrovertible, unalterable, and essential to good medical care without qualification?

2. *Closed Panel Systems*—What is or will be your attitude regarding physician participation in those systems of medical care which restrict free choice of physician?

These suggestions acknowledge that the policy of the American Medical Association to encourage and support the highest quality of medical care for all patients remains unchanged. They question, however, whether attitudes toward the free choice of physician and the closed panel system may be undergoing evolutionary change.

In accordance with the recommendations of the AMA House of Delegates that the Board of Trustees invite the constituent associations to forward their replies to these questions to the Executive Vice President sixty days in advance of the June, 1959 meeting, the Minnesota State Medical Association appointed a special committee to study the report. The committee, in making its recommendations to the Council of the Minnesota State Medical Association, stated "it is the opinion of this committee that the principle of free choice of physician is to be considered a fundamental principle essential to the best medical care."

The report continued:

"We would like to emphasize strongly that we are opposed to so-called 'close panel plans' which limit the free choice of physician. We are cognizant of the fact that in certain areas these plans are operating successfully to fulfill an apparent need. In these areas, the 'free choice of physician' has been necessarily jeopardized. Nevertheless, it is our opinion that alternative plans can be developed through the co-operation of medical societies and the individuals involved which will obviate the need for these so-called 'closed panel plans.' Furthermore, we need to re-emphasize the inherent danger to the future quality of medical care which is likely to be associated with the further development and spread of these closed panel plans."

MINNESOTA LABOR VIEWS AMA MEDICAL CARE REPORT

Very much the center of attention in organized labor circles, is the pending action which the AMA is expected to take at its 1959 Annual Meeting in Atlantic City, New Jersey, in June.

Recently, an editorial commentary on this important subject appeared in the *St. Paul Union Advocate* under the feature heading, "Looking Things over with Lock."

For your consideration, the following excerpts from that article have been reproduced as follows.

"The old American Medical Association is just as reactionary today as it was when Morris Fishbein dominated its conventions, its official organ, and its very thinking.

"And we make this assertion in the face of a recent top AMA commission's advice that the organization should adopt a 'judicious, tolerant and progressive attitude' toward prepaid medical care plans.

"Such a proposal, were it to be adopted by the 1959 annual convention of the AMA next June, would mark a drastic change from the association's present open hostility toward any and all plans not totally, completely controlled by members of the doctors' union. . . . The AMA envisions socialized medicine in every prepaid health plan ever put into operation; it fought the enactment of the federal social security law because its hard-shelled leaders considered it as just another wave in the direction of socialized medicine, and it will continue to see bogeys in everything designed to correct the very iniquities the medical trust has foisted on the great mass of suffering humanity.

"If socialized medicine ever comes to the USA, it will be because of the intolerance, the greed, the narrow-mindedness and the insolent conceit of the men who dominate the AMA."

FORAND BILL—A LA 1959

The Forand Bill (1959 version) was introduced in the House of Representatives, February 18. The proposed measure has undergone a certain amount of stream-lining. Provisions in the bill introduced in the House by Representative Aime Forand, Democrat from Rhode Island, now includes permitting surgical services to be performed by other than board-certified members. Financing the program would be accomplished by increasing social security taxes beyond increases already planned, by one-quarter of 1 per cent for both employe and employer and three-eighths of 1 per cent for the self-employed starting in 1960.

In addition, Mr. Forand has indicated that he intends to explore the possibility of (1) paying for diagnostic services, such as x-rays and laboratory tests, on an out-patient basis, and (2) including benefits for home nursing care through responsible agencies as visiting nurses association, hopitals or local health departments.

He points out:

"The AHA has recognized the need for some type of federal action and has been exploring alternatives. . . . The American Medical Association has also acknowledged the need for vigorous action along new lines and urged its member societies to explore and support private programs that will help to avoid federal legislation."

At this time, no definite date for hearings on this measure which proposes to use the social security system to provide hospitalization and surgical services for those eligible for OASI insurance benefits, have been scheduled.

DINGELL BILL HAS FAMILIAR RING

Senator James E. Murray, Democrat from Montana, and Representative John D. Dingell, Democrat from Michigan, have reached their perennial conclusion that compulsory national health insurance must be adopted to fill a need because the voluntary system "has failed entirely to reach a third of the people."

The duet of Wagner-Murray-Dingell fame has expressed this conclusion in conjunction with the introduction of a bill similar to that introduced by that trio some fifteen years ago.

According to the provisions of the suggested legislation, employers and employes would share the cost with the latter contributing a maximum of ninety dollars a year for complete health care of themselves and dependents.

In the past, measures authored by these proponents of compulsory national health insurance have received little attention. However, some observers feel that the current emphasis of Congress on health legislation might afford this measure serious consideration. A number of factors may make the Murray-Dingell Bill a strong 86th Session contender. Namely, in financing features, the bill does not rest on taxation mechanism, a deliberate omission to heighten chances of its being referred to House Commerce Committee rather than Ways and Means Committee.

Also, conveniently and strategically, Representative Dingell is a member of the former committee. Senate handling of the measure will probably be by the Labor and Public Welfare Committee in which Senator Murray ranks next to the chairman, rather than the Finance Committee.

SENATOR HUMPHREY IS ALSO HEALTH BILL MINDED

The Humphrey Bill (S.1511) a counterpart of the new Forand Bill, providing government paid surgical, hospital and nursing home care for beneficiaries of OASI, was recently sent to the Finance Committee. States Senator Humphrey on behalf of his measure:

"We in this great and wealthy country have a social and moral obligation to provide adequate means whereby the elderly may (be) free of constant anxiety over what will happen in time of serious illness."

THE MINNESOTA STATE MEDICAL ASSOCIATION FOUNDATION IS FORMED

The Minnesota State Medical Association Foundation, a non-profit corporation, has been formed by the Council of the Minnesota State Medical Association. The purposes of the corporation are as follows: (a) To engage in, advance, promote and administer charitable, educational and scientific activities and projects; (b) To aid, assist and contribute to the support of corporations, associations, and institutions, gifts to which are deductible from the income of a corporation under the provisions of the Internal Revenue Code; (c) To establish or create and to maintain, promote, endow and aid, any such corporation, institution or association; and (d) To render financial assistance to such members of the medical profession and their families and to such families of deceased members of the medical profession as may be indigent and as may be deemed worthy of such aid by the corporation.

IMPROVED GROUP LIFE INSURANCE PLANS ARE AVAILABLE TO MEMBERS

The Council and the Insurance Liaison Committee has announced major revisions in our group life insurance program, providing much greater benefit with broader policy provisions. The plan will now be available to all eligible members throughout the state. In addition, *Waiver of Premium* and *Double Indemnity* are now included; and the amount of coverage has been doubled, with very favorable premium adjustments.

Further, it is a "participating" policy, with dividends payable according to the experience of the group. Presently insured members will be given the privilege of conversion.

The Northwestern National Life Insurance Company remains the underwriter, and Charles O. Finley and Company have been named administrators.

Watch for additional detailed information regarding this outstanding opportunity.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

PHYSICIAN'S LICENSE SUSPENDED FOR FIVE YEARS FOR NARCOTIC VIOLATIONS

On February 20, 1959, the Minnesota State Board of Medical Examiners suspended for a period of five years the medical license held by Dr. Max M. Tenen, forty-two, 9104 Raviller Drive, Downey, California. In a citation issued by the Board for the revocation of his license, Dr. Tenen was charged with having habitually indulged in the use of demerol, dolophine, dilaudid and morphine sulphate, and with having illegally issued certain prescriptions for dilaudid in the name of another person, the prescriptions being later compounded and the drugs thereby obtained illegally diverted by him to his own use. It was also alleged in the citation that Dr. Tenen had entered a plea of guilty in the Municipal Court of Downey Judicial District, Los Angeles County, California, to a violation of the statues of the State of California regulating narcotics.

Although Dr. Tenen did not appear at the hearing before the Board on February 20, part of the evidence presented in support of the citation disclosed that on November 15, 1957, he was placed on two years' probation by the Court at Downey, California, for issuing false and fictitious prescriptions and for dispensing narcotics without making a record of each transaction showing the name of the patient, the date, the character and quantity of narcotics involved, and the pathology and purpose for which the narcotics were administered and dispensed. Following his conviction in Municipal Court, a proceeding was instituted against Dr. Tenen in regard to his medical license by the California Board of Medical Examiners and in an order dated August 29, 1958 the Board placed him on probation for a period of five years.

Dr. Tenen, who was born in Warsaw, Poland, on May 10, 1916, was awarded an M.D. degree by the University of Minnesota on June 13, 1942. He became a citizen of the United States upon the naturalization of his father on December 16, 1926, in Minneapolis. Since being licensed in California in 1945, Dr. Tenen has been located at Lynwood, Compton, and Downey, California.

THE POSTCHOLECYSTECTOMY SYNDROME

As a result of the reexamination of 220 patients who had undergone operations on the gallbladder not less than a year and a half earlier, the author presents a thoroughgoing analysis of the results. He emphasizes the importance of radiomanometric study during the operation, which, together with cholangiographic investigation, makes it a rare occurrence for stones to be left behind in either the cystic duct or the common bile duct. Overlooked stones and pathologic conditions in the bile ducts therefore command less concentrated attention from the surgeon than to hepatic changes that existed prior to operation, especially cholangitis, interstitial hepatitis and the various types of cirrhosis. Since these diseases are most frequently due to long-standing disease of the gallbladder, they should prove preventable, in many cases, by surgical intervention before complications occur. Absolute contraindications, such as extreme age, arteriosclerotic dementia and extraordinary obesity, are still valid except when the severity of the symptoms make operation unavoidable. — E. KAISER, M.D., *Journal of International College of Surgeons*, 31: 80-86 (Jan.) 1951.

History of Medicine in Minnesota

A MEDICAL HISTORY OF MEEKER COUNTY PRIOR TO 1900

HAROLD E. WILMOT, M.D.

Litchfield, Minnesota

(Continued from January issue)

Dr. George Newlands, regular, practiced in Litchfield at least as early as 1886, at which time his professional card appeared in the *Litchfield News Ledger* October 14 as physician and surgeon.

Dr. Rosenthal reports that he graduated from the Royal College of Physicians and Surgeons at Kingston, Ontario, probably also known as Queens Uinversity, Canada, 1879. He was licensed in Minnesota, December 31, 1883, as a regular physician, and his number was 656. The directories of 1890 show him in Litchfield, Minnesota, Meeker county, and in 1895 in Seattle, Washington. His death occurred there October 22, 1951, and was due to meningitis.

His first appearance in Meeker county is portrayed by his professional card appearing in the *News Ledger,* September 14, 1882:

"Drs. Kennedy and Newlands
Physicians and Surgeons"

We again find his presence in a courtesy card, January 4, 1883:

"Dr. George Newlands—Office on No. Marshall Ave.
Two doors So. of Methodist Church"

According to the *News Ledger* of November 15, 1883, he attended Ida Schnell who died.

W. R. Berens personally tells me he was vaccinated by him for smallpox in 1884 or 1886. According to the *News Ledger* he assisted in the operation on a skull fracture case about January 19, 1882, and that the patient died. April 12, 1883, we find his rooms moved over the post office. April 3, 1883, we find the allowance for care of county patients allotted to him by Meeker county in the amount of $184.50.

News Ledger, July 17, 1884—"Dr. George Newlands of this city was married to Miss Lizzie Burdick (a local girl—Ed.) at St. Paul, July 8th. Messrs. George Becker and Hamlet Stevens and Mesdames Ross, Cootes, Jackson and Miss Moore were present from this city. The happy couple started the same day for the doctor's old home at Kingston, Canada. They will return to this city in a few days, when the numerous friends will have an opportunity to extend congratulations."

Independent, May 12, 1885—"The arrival of a new daughter made Dr. and Mrs. Newlands happy on May 6th."

Independent, May 16, 1885—"Dr. Newlands was elected to be a delegate to the Minnesota State Democratic convention."

We find Dr. Newlands in April, 1886, 'building a new home and plastering under the roof."

Independent, January 25, 1887—"Infant son of Dr. Newlands died of lung fever."

Independent, March 19, 1889—"Dr. Newlands returned from a trip to the Puget Sound country and seemed to be favorably impressed with same."

News Ledger.—"Dr. Newlands will leave today for Seattle. His family will remain here for the summer."

Dr. Newlands was slender, dark, had a short beard, carried himself with dignity; was busy, well thought of, well dressed; had a well kept home; and drove nice horses. He belonged to the Episcopal church and was a Mason.

Dr. Enoch A. Baum.—We first hear of Dr. Baum in the *News Ledger* of February 7, 1884—

"E. A. Baum, well known in the neighborhood where he lives, to possess a sure cure for diphtheria, and also to be one of the most successful opticians in the state, will visit Litchfield the last week in March, and stay several days, at which time he will teach parties how to treat diphtheria and will treat any case of sore eyes, or other chronic disorder. For further particulars, inquire at this office. References: Jas Nelson, Thos. Ryckman, Staples Bros.—Manannah."

The Minnesota Medical Directory reports him licensed by exemption September 2, 1884, by affidavit of 1884; located at Litchfield where he continued to practice.

The A.M.A. reports that he died at seventy-seven years of age in Fergus Falls State Hospital after a six-year-illness with brain disease. He was buried in Lake Ripley cemetery June 23, 1908; age given as seventy-seven; cause of death: anemia.

A son, Clarence, visited him frequently while he was in Litchfield, and an M. E. Baum, a son, was proprietor of the Litchfield House for years, starting about 1885.

Independent, October 9, 1888—(Greenleaf News). "Dr. Baum was in town a few days last week."

News Ledger, October 18, 1888—The first appearance of his courtesy card reads as follows: "Dr. E. A. Baum will treat all chronic diseases, sore eyes, female weakness, cancers in all forms, disease of the skin and venereal diseases. May be found at the Litchfield House the first week in each month."

This card not seen after October 1, 1889. However Dr. Baum signed death reports as attending physician in 1892, 1893, 1894, and 1897.

News Ledger, April 8, 1897—"Dr. Baum is sixty-six years of age and last Monday he was flying around town like a young colt let out to pasture, all on account of a baby boy that arrived at his home the night before and who will call him Dad in the future."

Independent, July 11, 1899—"Criminal Operation. Clara Olson dead from that cause says jury. Dr. E. A. Baum charged with being guilty of the crime.

"Last Wednesday morning at the rooms occupied as a residence and office by E. A. Baum in the Snell block, occurred the death of Clara Olson, daughter of Christian Olson of Acton town under circumstances that led to an examination and inquest by Coroner William Hildebrandt and a jury.

"A post mortem examination was made by Drs. Bissel, Robertson, and Chapman.

"In their opinion, an operation for abortion had been performed. Dr. Baum claims he was treating the girl for venereal disease. Dr. Baum has been implicated in one similar case heretofore in which the girl recovered. He is not a practitioner of any regular school of medicine but has been practicing for a good many years. He is an old man and has been living in the county since its early days.

"There has been no arrest as yet.

"The Verdict: 'Said Clara Olson died at the residence of E. A. Baum in Litchfield, Meeker county, Minnesota, on July 5, 1899, as the result of a criminal operation known as abortion, by the hands of E. A. Baum.' Signed (Jurors—names listed)."

Independent, July 18, 1899—"Dr. Baum Arrested.

Coroner Hildebrandt swore out a complaint against Dr. Baum last week and he was taken before Justice Bissel (not Dr. Bissel—Ed.) and admitted to bail in the sum of $500.00. Preliminary hearing for next Friday, 21st."

Independent, July 25, 1899—"Accused bound over to Grand Jury. Bail fixed at $1,000. Defendent did not go on the stand in his own behalf."

Independent, November, 1899—"Plea Not Guilty. No Trial Yet."

Independent, February 27, 1900—(Court Cases). "Case of E. A. Baum was called. A jury secured about noon and the evidence on both sides took until the following noon. The case went to the jury in the afternoon, and they were out until the next morning when a verdict of 'Not Guilty' was the result of their deliberations."

In 1902 a professional card is as follows: "Dr. E. A. Baum—Specialty Female Troubles."

Dr. Baum was a small man with scanty beard; he had a poor practice, carried a small doctor's bag, and travelled mostly on foot. He was a Presbyterian.

Drs. C. A. and A. P. Woodward.—

News Ledger, December 18, 1884—"New Doctors. Drs. C. A. and A. P. Woodward, homeopathic physicians, have located in Litchfield for the practice of their profession. Dr. C. A. Woodward has for the past seven years been located at Glencoe, and is doubtless known to some of the southern residents of this county. His brother, A. P., has for ten years been located at Cannon Falls. After looking the country over, they have decided upon this point to enter into the practice together and their office in the future will be over J. L. Wakefield's store. They are men of gentlemanly appearance and have each had years of experience. There is a large scope of country surrounding Litchfield that has no homeopathic representative and doubtless there are many who have faith in that branch of the practice of medicine who will heartily welcome their coming."

News Ledger, December 18, 1884—"While at Wahpeton a short time ago, Drs. Woodward were requested to perform a surgical operation upon a boy who had his leg crushed by a threshing machine. They amputated the leg and in so doing, Dr. C. A. got his right hand blood poisoned and came near losing his life. It began to affect his arm, but they succeeded in stopping its further progress. He is now carrying the injured hand in a sling."

News Ledger, December 18, 1884—(Professional Card)

"C. A. Woodward A. P. Woodward
Woodward Bros.
Homeopathic Physicians and Surgeons
Diseases of Women a Specialty
Office over Wakefield's Store"

Independent, February 3, 1885—"Woodward Brothers, the homeopathic physicians, who established themselves here a few weeks ago, have already decided to leave. One will locate in Glencoe and the other in Hutchinson. They will depart today."

News Ledger, May 30, 1889—(Dassel News). "Woodward Bros., homeopathic physicians, advertise to be in Dassel the fore part of each week occupying parlors in the Dassel House."

Dr. R. H. Wood was listed in Forest City by the Medical Register in 1886. No news items are available. Perhaps he never arrived.

Dr. J. H. Bowers.—The first note we have on Dr. J. H. Bowers, a homeopath, is found in the *Litchfield Independent* of July 14, 1885:

"Dr. J. H. Bowers of La Porte, Indiana, an experienced physician of the homeopathic school was in town one day last week looking over the ground with the view of a permanent settlement. The doctor seems to be a fine gentleman and a man of considerable experience. He is well pleased with the town and country and, in all human probability, will be with us to stay ere long.

The doctor has written since that he will be in Litchfield about July 22 or 25 to make it his permanent home. Will probably move into Mrs. Hart's home on the north side of the park."

Courtesy cards appeared in both papers:

"J. H. Bowers, M.D.
HOMEOPATHIC PHYSICIAN
Litchfield, Minn.
Office at residence northwest corner of Marshall Ave. & 4th St."

April 27, 1886—*Litchfield Independent Review.* "Dr. Bowers was called to Herman, Minnesota, to attend ill child."

September 12, 1886—*Litchfield Independent Review.* "Dr. Bowers moved into house three doors north of Episcopal church."

April 26, 1887—*Litchfield Independent Review.* "Dr. J. H. Bower's wife's father, Nathaniel *Pullman,* died suddenly in Minneapolis. He had made many inventions in constant use in the railway business." (Pullman Sleepers?)

There were other notes in the papers on moving into a new house in 1888 and attending various patients.

Then the *Independent* of August 14, 1888, states:

"Dr. J. H. Bowers has decided to leave Litchfield and locate in Menomonee, Wisconsin. He is a reliable man and a good citizen and we are sorry to see him leave. Mrs. Bowers will remain a month or two."

News Ledger, August 16, 1888—"Dr. J. H. Bowers left last week for Menomonee, Wisconsin, where he expects to establish himself for the future. The doctor is counted among the best of the homeopathic school, is a good citizen and the well wishes of Litchfield follow him to his new home."

Dr. Bowers was listed in the medical record in Litchfield as of 1890 but no doubt moved before its publication. He was also listed in Herman, Minnesota, during the same year but marked as having removed from the state.

In 1895 and 1905 he was listed in Renville, Iowa. In 1909, no address listed. He died July 10, 1920, cause unknown.

Dr. William J. Bahnsen.—On Dr. Bahnsen, regular, the *Independent* of July 21, 1885, carries this item in Cedar Mills News:

"Dr. W. J. Bahnsen of Chicago arrived last Friday. His office at present is in the old store building. The doctor comes well recommended."

Dr. Rosenthal has uncovered a very interesting tale about this man. He was born July 30, 1858, in Hamburg, Germany, and came to the United States at the age of seven, living at first in Rock Island, Illinois. After getting some education, he tried his hand in some mercantile establishments. He started his medical education at the Medical College in Minneapolis where he remained one term. Then he attended a course of lectures at the Chicago College of Physicians and Surgeons. Following that, he took a course at Bellevue Hospital in New York. He returned to Chicago and graduated with honors from the Chicago Physicians and Surgeons College in 1885.

He practiced in Cedar Mills, Meeker county, about one year.

Independent, July 28, 1885—"Dr. Bahnsen dressed a wounded finger."
"Dr. Bahnsen took care of Eves and they are getting well."

Independent, September 8, 1885—"Dr. Bahnsen had a meeting appointed for those af-

flicted with eye troubles, but could not attend to the cases as some ordered instruments and expected assistance did not arrive in time."

Independent, December 1, 1885—"Dr. Bahnsen, the physician who stayed with us the last three months, left on Thursday for Chicago to complete his studies as an eye and ear specialist, and Dr. Vollmer came from Ohio to take his place as a resident physician. Dr. Vollmer is a German and comes highly recommended."

Dr. Rosenthal states that following his brief stay in Meeker county, Dr. Bahnsen went to Europe where he studied and worked for about one and one-half years. He received diplomas from the Universities of Berlin and Heidelburg. He settled in Fisher, Polk county, in May, 1887. He was able in six months to establish a fine reputation in Fisher, especially as a surgeon. He had a fine personality and was a "natural born physician."

His untimely death was caused by being shot in the back of the head as he was getting on the train after making a country call near Fisher, in August of 1890. At that time he had established his practice in Crookston. The assassin was apparently freed, and the reason for the attack is unknown. It was thought that he was taken after the assault to Grand Forks, North Dakota, and died there, but no death reports are available.

Dr. Bahnsen was the third of nine children and was survived by six siblings and his widow, who was Annie Elbie before her marriage to the doctor. There were no children.

Dr. Stiles S. Squires.—A news item of August 23, 1888, states: "Dr. S. S. Squires, a homeopathist, has located in this city and will fill the place made vacant by the departure of Dr. Bowers. Dr. Squires is a man of middle age, has had years of practical experience and appears to be a gentleman thoroughly posted in his work. His office will be at his residence in the Hart home, northeast corner of Central Park." His professional card appears in the same issue.

He was a member of the Prohibition Party and chairman of the executive committee of the same for Meeker county. He was a delegate to the State Convention of the Prohibition Party.

He made trips to Manannah on Tuesday and Friday of each week in 1899.

He was licensed under the "Affidavit of Years of Practice Prior to 1887" and listed in Litchfield in 1898 in the Minnesota Directory. He was listed in the A.M.A. Directories 1886 to 1890 at Tracy, Lyon county, Minnesota. He was last listed at Newport, Washington, up until 1908.

The last appearance of his professional card appeared here in the *Litchfield Independent* on February 6, 1900.

He had a son who ran a confectionery store here.

He was described as short, gray haired, and wore square "whiskers." He belonged to the Methodist church and was quite a singer, and is reported to have been buried in Ripley cemetery, though I found no listing in the cemetery association records.

Dr. J. Vollmer.—

Independent, December 1, 1885—"Dr. Vollmer arrived in Cedar Mills to take over the practice of Dr. Bahnsen who left for further study. He came from Ohio, was of German extraction, and probably educated in Germany. His work was much appreciated by his neighbors and patients."

Independent, December 8, 1885—"Dr. Vollmer, assisted by Dr. Bahnsen, has performed a successful operation on Mrs. R. Martin, taking a large tumor out of her side. Mrs. Martin is doing as well as circumstances permit."

Independent, January 19, 1886—"Dr. Vollmer, unused to the ways of a cutter, upset in a snow bank and the horse ran away, but he hired a bobsled and finished making his call."

Independent, April 6, 1886—"Dr. Vollmer was thrown from his buggy and badly hurt."

Independent, July 13, 1886—"Dr. Vollmer treated a patient with a crippled foot."

Independent, September 21, 1886—Speaking of the county fair: "And in some other departments, our productions are worth looking at, not the least noticeable is the nice bracket work of Dr. Vollmer. His bird cages, work boxes, picture frames, and other work are very fine. He is undoubtedly very industrious as he gives excellent satisfaction as a physician."

Independent, October 9, 1888—"It has now become a certainty that we are to lose our doctor and his family. They will move to Hutchinson this week. We heartily recommend him to anyone in need of a physician. His intelligent and accomplished wife will be greatly missed in the social circles."

Dr. Edwin A. Skaro, regular, came to Dassel from Minneapolis in 1886 but returned to Minneapolis in 1888. From word of mouth, he exhibited some peculiarities of personality and found Dassel unsuited for him.

Independent, March 22, 1887—(Courtesy Card)

"Dr. E. A. Skaro
Physician and Surgeon
Scandinavian Doctor
Office above Lion Drug Store
Dassel, Minn."

This card was missing on and after June 7, 1887.

Transcripts of Minnesota Medicine list him with Minnesota License No. 1320, issued March 12, 1887, and that he was a graduate of the Minnesota Hospital College of 1887. He was further listed in Minnesota Medical Directories in Dassel 1890 and Minneapolis in 1903 and 1909. He signed a death certificate in Meeker county in 1890 and 1899. He was not listed by the A.M.A.

Dr. William Hambroer, Eden Valley, graduated in 1883 from Bennett College of Eclectic Medicine and Surgery, and evidently came to Eden Valley soon after. He was of German extraction. Polk's Medical Directory listed him in Eden Valley in 1893. His signature appears on death certificates in 1889, 1891 and 1896.

In January, 1899, a news item describes his having finished three furnaces: one for his office, one for his home, and one for the Warner Hardware. Evidently he was something of an iron worker, and did this work as a side line.

Another news item of April, 1899 states that the doctor would need an assistant at present.

In April of 1899 we read that he "sold his residence and all his drugs, patent medicines, etc., to Mr. Williams, a druggist, who will take possession in the near future. The doctor will remain in Eden Valley and take life easy."

He retired in favor of Dr. Ridgeway in 1899 but continued to act in some capacity, for we read in February, 1903: "Dr. Hambroer, Health Officer of Eden Valley Village and Manannah township, publishes in the *Eden Valley Journal* a card prohibiting the holding of dances anywhere in the township on account of the prevalence of smallpox."

Dr. John Howard Kauffman.—As previously noted, Dr. Kauffman purchased Dr. McCollom's practice in Dassel in January of 1887, and remained there until 1911 when he removed to Currie, Minnesota.

He was born in Martinsburg, West Virginia, October 28, 1859. He was the son of Henry and Mary (Wilkins) Kauffman. His father for many years operated a drug store in Newburgh, Cumberland county, Pennsylvania. He received his early education locally and worked in his father's store, and on attaining his majority was taken into partnership by his father. In the fall of 1881 he entered Jefferson Medical College at Philadelphia, finishing two terms there, then entering the College of the City of New York. He returned to Newburgh, Pennsylvania, and practiced and conducted the drug business until 1887, when he sold out intending to start practice in Dakota Territory. On reaching Minneapolis he changed his mind and went to Dassel.

Excerpts from the Municipal Progress, 1899, give us this: "Dr. Kauffman enjoys an extensive patronage throughout this and adjoining counties; he is a thorough believer in the future of Dassel and is the owner of some of the most valuable and desirable business and residence property in the village. He is a worthy example of the medical profession, an esteemed citizen, a note worthy practitioner, and an ardent friend to social and municipal progress. Although a most busy man, Dr. Kauffman finds time to promote the best interests of Dassel. He is a 32nd Degree Mason and a Shriner and a member of I.O.O.F., M.W.A., and K.P. fraternities."

He possessed Minnesota Medical License No. 1400, dated May 11, 1887 (by diploma), and Minnesota Basic Science Certificate No. 2466, dated January 10, 1927 (by previous licensure). He is listed in our medical directories in Dassel from 1890 through 1909, and in 1928 in Currie, Minnesota.

Independent, 1887—"Dr. Kauffman is caring for diptheria cases."

Independent, April 18, 1889—"Dr. Woodward has left Dassel for Minneapolis. Dr. Kauffman is moving over the store of Oslund and Leighton."

News Ledger, August 8, 1889—"We learn that Mr. Steel who is studying with Dr. Kauffman will, when he completes his college course, become a partner of Dassel's popular doctor. Mr. Steele seems particularly adapted to that profession."

Independent, April 3, 1888—"Dr. Kauffman's wife arrived from the East."

News Ledger, April 5, 1892—(Courtesy Card)

"Dr. John H. Kauffman
Physician and Surgeon
Dassel, Minn."

News Ledger, May 27, 1897—"Dr. J. H. Kauffman is attending a typhoid patient."

News Ledger, March 9, 1898—"Dr. J. H. Kaufman was elected president of the City Council at Dassel at the recent election."

News Ledger, April 5, 1898—"Dassel merchants are fast selling out. Week before last, R. F. Case, druggist, one of the oldest businessmen of Dassel, sold his whole outfit to Dr. J. H. Kauffman who immediately took possession. Consideration, $5,500, including dwelling house as well as store."

Dr. Kauffman has been described as fine looking, single, a great beau, highly thought of. Gossip has it that his office girl committed suicide over him. Certainly he was married, inasmuch as the arrival of his wife is noted in the newspaper in 1888. There were no children.

Dr. Kauffman died January 7, 1933, in St. Joseph's Hospital, Saint Paul, at seventy-four years of age from mesenteric thrombosis and intestinal obstruction of two days' duration. Funeral services were under auspices of Ancient Landmark Lodge No. 5 A.F. & A.M. of Saint Paul, and interment was made in Oakland cemetery, Saint Paul.

The Art of Medicine

PR

Carl H. Woyke, B.A.
Editor

WANT 1959 PR SUGGESTIONS? HERE ARE A FEW

The AMA recently listed as top priority for 1959, the following practical public service projects. The suggested projects have been designed to approach the public on a grass-roots basis. Suggestions for 1959 county society and/or individual physician participation include the following.

Aging—Medicine's greatest problem right now is that of financing medical care for the patient over sixty-five. It is imperative that every society begins work on the problem immediately before government legislates an undesirable remedy. Each doctor can start in his own office by following the House of Delegates' suggestion that physicians help develop special insurance for those over sixty-five by accepting a level of compensation for medical services rendered which takes into consideration the needs and financial resources of the aged. Medical societies are urged to establish committees on aging which work closely with society PR committees and community groups. Societies will find helpful ideas for forming their aging program in AMA's "Medicine's Blueprint for the New Era of Aging."

Legislation—Societies should keep in mind that many of the long range goals of medical public relations will be realized by the enactment of legislation. So legislative groundwork must be laid from the very beginnig. Invite your government representatives to a society meeting this year to discuss up-coming bills in the medical field. Keep in constant touch with them throughout the year to let them know your society's views.

Food Faddism—Health education is a vital part of medical public relations. This year AMA can supply your society with a complete set of materials to help you expose the food fallacy racket. Order a campaign kit from The Minnesota State Medical Association.

Automobile Seat Belt Campaign—Experiments show that deaths resulting from automobile collisions could be drastically reduced if more people bought and used seat belts. This spring the National Safety Council, U. S. Public Health Service and AMA will sponsor a drive to promote the use of seat belts. Your society will be notified of available campaign materials soon, so plan to spearhead a drive in your community.

Co-operation with Labor Unions—Many unions are actively engaged in public service projects close to the interests of medical societies. By volunteering your society's support in these programs and enlisting union co-operation with such projects as seat belt and food faddism campaigns you may pave the way to better rapport over more controversial issues.

Athletic Injuries Clinics—Although the sports field is usually the most dangerous spot on the high school campus, proper preparation for the care of injured athletes is often conspicuous by its absence. To mend this gap in local school programs medical societies are urged to meet with coaches and school administrators to discuss proper treatment of athletic injuries. AMA's booklet "Protecting the Health of the High School Athlete" is a helpful guide for setting up an injuries clinic.

Disciplinary Structure—No profession can build stature without first accepting responsibility for its members' behavior. That's why no society PR program is complete without an effective disciplinary structure. So take time out to re-evaluate your society's mediation committee or disciplinary structure. Is it honestly fulfilling its original function? Is the public aware of this service?

Press Relations—Resolve this year to call on the editor of your local paper and interest him in at least one story about the good things doctors are doing in your town. Remember—most news is sent to the newspaper so your story stands the best chance of being printed if you bring your idea to the editor in person. Talk the matter over with him, he is usually a ready listener.

Free Choice of Physician—AMA's campaign to educate the people on the advantages of choosing their own family physician will continue full steam ahead. Those societies wishing to promote the campaign in their own communities may order a kit of promotional materials from the Minnesota State Medical Association.

Additional possibilities for county society projects suggested are: *Disaster Planning; Poison Control; Study of Better Business Management Practices for Doctors' Offices; Assistance to the Mentally Ill or Alcoholic.*

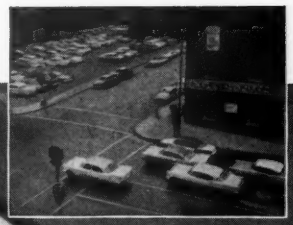
Your State Association is ready to help you put these projects in action. Whenever additional assistance is desired, our organization has at its disposal vast resources of the Communications Division of American Medical Association material. Available are a wide selection of sound motion picture films, exhibits, pamphlets, sample speeches, radio and TV scripts, guides and other PR aids.

IT'S IN THE BOOK . . . THE MEDICAL DIRECTORY, THAT IS

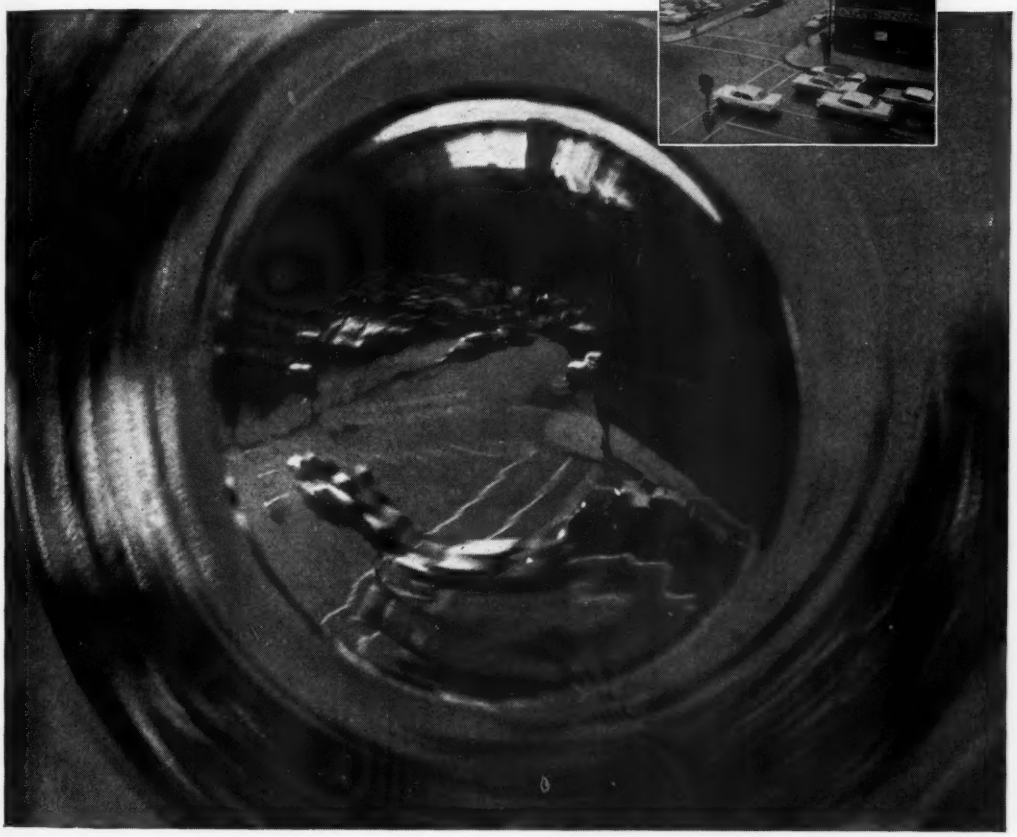
Every year the Academy of Medicine of Cincinnati, Ohio, publishes a medical directory of Greater Cincinnati.

The book contains a roster of society members and officers, Academy of Pharmacy members, as well as a list of medical suppliers, pharmacies, laboratories, rest homes, hospitals and welfare agencies. In keeping with its purpose of supplying doctors with all the different kinds of information they might need in their daily practice, the book also contains *the society's medico-legal code; policies for advertising, speaking engagements, radio and TV appearances* and pertinent state medical statutes.

In addition, the publication includes answers to such questions as "Where can I order a hearing aid for a patient?" and "What community agency is equipped to help an indigency case?", as well as other general emergency information.



PHYSICIAN INTEREST IN EDUCATION AT HIGH SCHOOL LEVEL



Physicians in Quincy, Illinois, through the Swanberg Medical Foundation of the Adams County Medical Society, have been putting on an educational campaign to arouse the interest of the profession in education at the high school level. They are urging county medical societies to co-operate with high school officials to grant awards to graduating students for high scholarship achievement, especially in academic subjects, to help motivate them to seek a college education. They claim if this were carried out throughout the nation, it would help America win "the cold war of classrooms" in which we are now engaged; that we are very much handicapped in the cold war because about 50 per cent of our brightest high school students do not go to college (or take the proper subjects at school).

The efforts at Quincy were initiated in 1956 (one and one-half years before Sputnik 1) by physician-members of the Kiwanis Club of Quincy and the Swanberg Kiwanis Foundation of that club, when they sponsored what is known as the Quincy Major Learning Program. This program is devoted to the guidance and motivation of the superior and talented high school students of Quincy and Adams County (Illinois) to seek a college education. The Kiwanis Foundation has just published an interesting leaflet for high school students entitled, "Are You About to Choose Your High School Courses?". This well-written, easy-to-read leaflet should do much to induce students in the upper half of their class, to pursue the proper subjects in high school to insure admission to the college of their choice. On January 19, 1959, the program (through the Kiwanis Foundation) was accorded national recognition when it received the 1958 B.V.D. Community School Improvement Award as the "most outstanding citizen-effort toward the betterment of the schools" on a community basis in the East Central Region of the United States, which comprises the states of Alabama, Illinois, Indiana, Kentucky, Michigan, Mississippi, Ohio, Tennessee and Wisconsin.

Dr. Swanberg, "sparkplug" of the educational plan, is quoted in the J.A.M.A. article: "What a wonderful achievement it would be for the nation if county medical societies all over the country would give high school academic scholarship awards. How well we succeed in education of each child to the maximum of his potential will untimately determine his fate and our own."

CONTROL VERTIGO, DIZZINESS... AND ELEVATE THE MOOD

with **Dramamine-*D*®**

brand of dimenhydrinate with dextro-amphetamine sulfate

"Disturbances of balance resulting from vestibular disorders have long been known to lead to severe anxiety."*

Vertigo—whether of organic or functional origin—tends to leave depression in its wake. Dramamine-*D* is a therapeutic combination designed for treatment of the entire vertigo-reaction syndrome. Each tablet contains dimenhydrinate (50 mg.) to control dizziness, and dextro-amphetamine sulfate (5 mg.) to elevate the mood.

*Pratt, R. T. C., and McKenzie, W.: Anxiety States Following Vestibular Disorders, Lancet 2:347 (Aug. 16) 1958.

Dramamine® available as tablets, ampuls, liquid, suppositories

Research in the Service of Medicine **SEARLE**

Minnesota Blue Shield—Blue Cross

Each Blue Shield Medical Service Report form contains a space in which to enter the birth date of the patient. The form pertaining to this matter is as follows:

NAME OF PATIENT ———— PATIENT'S DATE OF BIRTH ————

Many reports are being submitted without the birth date of the patient, and whenever possible the reports are processed without obtaining this information. However, there are numerous reasons why this information is increasingly important, and should be included on every future report.

Minnesota Blue Shield, and all other Blue Shield Plans, has been requested to consider methods of providing coverage for the older persons whose numbers are constantly increasing. If Blue Shield is to give special consideration to coverage for the aged, it is first necessary to have some facts and figures on the number of persons included in the category of retired persons or senior citizens, the number of persons approaching retirement age, and the type and cost of services rendered these persons. Thus, the birth date of the patient on each Medical Service Report would enable Blue Shield to accumulate accurate data necessary for a study of such matters. Such information is also of intense interest to the medical profession and the public at this time. Equally important is that these data will be of help in future planning of all phases of Blue Shield coverage.

There are no age limits for group subscribers under Minnesota Blue Shield. Persons under sixty-five years of age who are in satisfactory health are eligible for non-group enrollment. After enrollment, coverage is never cancelled because of age. Furthermore, retirees can convert to non-group contracts with no decrease in coverage.

As of January 1, 1958, limited information at hand indicated that more than 60,000 Minnesota Blue Shield subscribers were sixty-five or more years of age. Blue Shield can logically anticipate an even greater number of participant subscribers sixty-five or more years of age in the future.

In a letter to Minnesota Blue Shield physicians, R. T. Crist, president of Minnesota Blue Cross, reported that the amendment to the Blue Cross contract excluding benefits for diagnostic care and routine physical examinations has been received enthusiastically by doctors, unions, and management.

"Hundreds of doctors have been called by phone in an effort to clarify diagnosis terminology," Mr. Crist explained. "Practically 100 per cent of these doctors have co-operated enthusiastically. Most doctors expressed a desire to help in any way possible," he continued.

Mr. Crist went on to say that from all indications, all phone calls and discussions with doctors throughout the state have begun to bear fruit, and that this would not have been possible without the complete co-operation of the doctors.

Mr. Crist concluded by promising to report further at a future date.

waterloo for an ulcer...

oleon exhibited ulcer symptoms through most of adult life, yet he scorned medication for his ever-ing "spasms of nervous origin." He ignored his mities with violent naïveté despite an intense in-st in medical science. Thus, the classic hand-in- pose may have been the result of his paroxysms astric pain that sliced "like the stab of a penknife."

en your patient is besieged with an ulcer, bins provides you with an armamentarium icient to repel it.

ntal assault—If your tactics dictate Local ion, try ROBALATE,® which is dihydroxy minum aminoacetate (0.5 Gm. per tablet or), an antacid of definitely superior efficacy.

irclement — If you prefer to approach the r Systemically, prescribe NNATAL,® the anticholinergic-antispasmodic-sedative with the time-tested *natural* belladonna alkaloids and phenobarbital, a veteran campaigner without peer. FORMULA: hyoscyamine sulfate, 0.1037 mg.; atropine sulfate, 0.0194 mg.; hyoscine hydrobromide, 0.0065 mg.; and phenobarbital (¼ gr.), 16.2 mg.

multi-pronged attack — If you relish the strategy of combining antacid and antispasmodic-anticholinergic effects, use DONNALATE ® It combines one-half of a DONNATAL tablet with one ROBALATE, ideal allies for comprehensive ulcer therapy.

Victory will be yours.

SPONTIN IN SERIOUS

A Special Report from Abbott
to the Medical Profession
on a Year's Clinical Experience
with SPONTIN®
(Ristocetin, Abbott)

In a Spanish province, a patient lay dying of endocarditis. A short wave radio appeal for SPONTIN was intercepted by a Baltimore physician. The antibiotic was immediately flown to this faraway land, and 10 days later—the patient had recovered.

In Chicago, a moribund patient had been administered 18 combinations of 10 different antibiotics without success. Involved was a hospital-acquired staphylococcal pneumonia—plus complications. SPONTIN was substituted and the patient lived.

A five-week-old infant was critically ill with staphylococcal enteritis. Treatment failures included erythromycin and chloramphenicol. Three days of SPONTIN saved this life. The list is long and impressive and it grows daily.

Recently, a study[1] was made of serious and resistant staphylococcal infections reported to Abbott Laboratories. Many of these cases had serious complicating diseases—many were moribund, or almost so, at the time SPONTIN was started. Yet, out of the 160 staphylococcal cases studied, 93 were reported cured and 38 improved after the administration of SPONTIN.

Out of the total of 251 patients with severe infections caused by gram-positive or mixed organisms, 149 were reported cured and 53 others improved. And the record for pediatric practice was every bit as good.

Additionally, SPONTIN continues to exhibit exceptional bactericidal activity against coccal infections[2]. And, according to another study, SPONTIN provides successful short-term therapy in endocarditis[3].

901066

Only last October, at the Antibiotics Symposium in Washington, D. C., a panel of six leading antibiotic experts placed SPONTIN at the top of all other commercially-available antibiotics for treating serious staphylococcal infections. Also, six papers—all dealing with the effectiveness of ristocetin (SPONTIN®) in treating staphylococcal infections—were presented at the Symposium.

One of the most encouraging aspects of the year's literature on SPONTIN is the increasing testimony to its safety. As the months have passed and cases have accumulated by the hundreds, it has become apparent that careful attention to dosage recommendations has practically eliminated toxicity and side effects as serious obstacles to therapy. Also, recent improvements have been made in the manufacture of SPONTIN; the drug is now made from pure crystals.

A recent report[4] in the Journal of the American Medical Association concluded, "It is our opinion that, if proper precautions are observed, ristocetin is a [well tolerated] and potent agent to employ in the treatment of staphylococcal infections." And in another study, after successfully treating 28 patients with a variety of staphylococcal infections, the authors reported[5], "No serious complications were noted."

Few more dramatic records have been written in such a short space of time. SPONTIN has proved itself to be a good answer, perhaps the best answer at present, to the resistant staphylococcal problem—and of real value in other serious coccal infections. It may well be your answer when you're confronted with a serious infection.

Abbott

STAPHYLOCOCCAL INFECTIONS

Excerpts from Reports Read at the Antibiotics Symposium

Spontin In Treating Severe Respiratory Infections –"In 13 of 20 patients the results were excellent, with clinical response being evident within one to four days after institution of therapy. In three additional patients, there was some degree of improvement in pneumonic processes superimposed on tuberculosis in two cases and on pulmonary neoplasm in one. In all other cases, serious antecedent pathology undoubtedly influenced the negative or equivocal response to ristocetin therapy.[6]"

Spontin In Treating Staphylococcal Infections—After successfully treating 28 patients, the authors wrote, "Ristocetin or Spontin has proved to be bactericidal and bacteriostatic, particularly for the *Staphylococcus aureus*, which is often resistant to many other antibiotics.[5]"

Spontin In Treating Seven Difficult Cases – "Ristocetin has produced excellent results in eradicating, mitigating or preventing infection in seven selected difficult cases. Six of the seven cases involved *Staphylococcus aureus* which did not respond to chemotherapy with other antibiotics.[7]"

Spontin Blood Levels In Children – "Ristocetin was administered as a single intravenous injection of 12.5 milligrams per kilogram. This resulted in serum levels ranging from 1.3 to 10.6 mcg. after two hours with a gradual fall to a level of 0.7 mcg. per cubic centimeter or less after 12 hours.[8]"

Spontin In Treating Staphylococcal Pneumonia –"Ristocetin was used in the treatment of 24 patients with staphylococcal pneumonia, 17 of whom had failed to respond to previously administered antibiotics. Complete clearing of pneumonitis was obtained in 16 patients and significant improvement occurred in two others. Two patients died of pneumonia; four others succumbed to other lethal diseases.[9]"

Spontin In Treating Children and Adults – "Ristocetin completely controlled severe staphylococcal infections in 11 adults and six children who received adequate therapy.[10]"

REGIONAL POISON CENTERS EXTENDED IN MINNESOTA

The Minnesota Poison Information network is gradually expanding its operations for giving assistance to physicians confronted with accidental poisoning problems involving trade-named household, commercial, agricultural, and industrial products not identified of their ingredients.†

A substantial number of centers have been and are being organized on a relatively local basis, i.e., small groups of counties. Physicians requiring information should contact the Regional Center serving their county in accordance with the following schedule. Other centers serving other areas of the State will be announced in the near future.

†For detailed information, see article entitled "The Minnesota Poison Information Center Network" in the November 1958 issue, page 767.

POISON CENTERS

Hennepin, Scott, Rice, Sibley, Carver, McLeod, Wright:
- Fairview Hospital, FE 6-6691
- Minneapolis General Hospital, FE 3-1178
- North Memorial Hospital, JU 8-2753
- Northwestern Hospital, FE 2-7266

Ramsey, Dakota, Washington, Anoka, Chisago:
- Ancker Hospital, CA 2-7341
- Bethesda Hospital, CA 4-7561
- Children's Hospital, CA 7-6521
- St. John's Hospital, PR 1-5521
- St. Joseph's Hospital, CA 2-6321
- St. Luke's Hospital, CA 2-6644

Blue Earth, Freeborn, Waseca, Faribault, Martin, Watonwan, Brown, Nicollet, Le Sueur:
- Immanual Hospital—Mankato
  Mankato 8-1605

Nobles, Rock, Pipestone, Murray, Cottonwood, Jackson:
- Worthington Muncipal Hospital
  Worthington 2-5601

Ottertail, Becker, Clay, Wilkin, Grant, Douglas, Todd, Wadena:
- Lake Region Hospital—Fergus Falls
  Fergus Falls 523

St. Louis, Lake, Cook, Carlton, Pine, Aitkin:
- St. Luke's Hospital—Duluth, RA 7-6636

ULCER CONTROL

all day

NEW

DARICON*

oxyphencyclimine hydrochloride

TABLETS

all night

patient comfort

Natural Prolonged Action–The action of DARICON, a more potent and better tolerated anticholinergic, is consistently prolonged because it has a unique chemical structure and is not dependent on "mechanical" means (e.g., special coating, adsorption on ion-exchange resin).

In addition to peptic ulcer, DARICON is also indicated for other gastrointestinal disorders characterized by hypersecretion, hypermotility and spasm (e.g., functional bowel syndrome, chronic nonspecific ulcerative colitis and biliary tract disease).

Dosage: 10 mg. b.i.d. (morning and evening). Supply: Tablets, 10 mg., white, scored. Bottles of 60 and 500.

MEDICAL CONTINUATION COURSES

Medical Continuation Courses, Center for Continuation Study, University of Minnesota, to be presented:

May 11-15 Introduction to Electrocardiography for General Physicians
May 18-22 Proctology for General Physicians
May 27-29 Otolaryngology for Specialists
June 15-17 Gynecology for General Physicians

For further information concerning the above courses, write to the Director, Department of Continuation Medical Education, 1342 Mayo Memorial, University of Minnesota, Minneapolis 14, Minnesota.

PEDIATRIC SHORT COURSES

Pediatric Short Courses offered by the Children's Hospital of Philadelphia and the Graduate School of Medicine, University of Pennsylvania. Course selections include: Pediatric Advances, May 25-29, 1959; Practical Pediatric Hematology, June 1-5, 1959. Inquiries should be addressed to Irving J. Wolman, M.D., Director of Post-Graduate Education, The Children's Hospital of Philadelphia, 1740 Bainbridge Street, Philadelphia 46, Pennsylvania.

RADIATION PROTECTION MOTION PICTURE FOR PHYSICIANS

A motion picture illustrating the medical aspects of radiation, including protective measures in diagnostic radiologic examinations, will be distributed soon by the American College of Radiology to the nation's physicians.

Supervising production of the 16 mm., half-hour color film will be a special committee of the American College of Radiology under the chairmanship of Wendell G. Scott, M.D., Professor of Clinical Radiology, Washington University School of Medicine, St. Louis, Missouri.

A workhorse "mycin" for common infections

respiratory infections

prompt, high blood levels

consistently reliable and reproducible blood levels

minimal adverse reactions

With well-tolerated CYCLAMYCIN, you will find it possible to control many common infections rapidly and to do so with remarkable freedom from untoward reactions. CYCLAMYCIN is indicated in numerous bacterial invasions of the respiratory system—lobar pneumonia, bronchopneumonia, tracheitis, bronchitis, and other acute infections. It has been proved effective against a wide range of organisms, such as pneumococci, H. influenzae, streptococci, and many strains of staphylococci, including some resistant to other "mycins." Supplied as Capsules, 125 and 250 mg., vials of 36; Oral Suspension, 125 mg. per 5-cc. teaspoonful, bottles of 2 fl. oz.

Woman's Auxiliary

ANNUAL MEETING DRAWS NEAR

"The Physician's Wife—Generalist," will be the title of the address to be presented by Mrs. Aaron Margulis, Sante Fe, New Mexico, guest speaker at the annual luncheon of the Woman's Auxiliary to the Minnesota State Medical Association, Tuesday, May 26, at 1:00 p.m., in the Ballroom of the Hotel Duluth. Mrs. Margulis is National Committee Chairman of Mental Health of the Woman's Auxiliary to the American Medical Association.

The annual luncheon will mark one of the highlights of the 37th Annual Meeting of the Auxiliary, May 25, 26 and 27, in Duluth.

Hostesses for this year's event are members of the St. Louis County Medical Auxiliary. Auxiliary members are encouraged to take advantage of unique vacation-land setting when attending this year's annual meeting.

The General Arrangements Committee notes that Duluth's seventy-four natural parks, Skyline Parkway, Enger Memorial Observation Tower, Minnesota Point Recreational Area, and the Aerial Bridge will indeed complement the stay of auxiliary members and their physician husbands in Duluth during the annual three-day event.

Additional highlights include the following: Executive Board meeting and luncheon, Monday morning, May 25, Kitchi Gammi Club; Tea at the Tweed Art Gallery, Monday, beginning at 3:00 p.m. (this is open to all visiting women through the courtesy of the St. Louis County Medical Auxiliary, cars leave the front entrance of Hotel Duluth from 2:45 to 4:00 p.m.); Annual meeting in the Arrowhead Room of Hotel Duluth beginning promptly at 9:30 a.m., Tuesday, May 26; "Roundup Breakfast" at the Duluth Woman's Club, Wednesday, May 27, at 10:30 a.m.

A more complete summary of events will be included in the printed program. The preliminary program appears elsewhere in this issue.

PRESIDENTS' CONFERENCE

The 15th Annual Conference for Presidents and Presidents-Elect was held in Chicago at the Drake Hotel, October 6-8, 1958. Mrs. Harold H. Feslerand, Mrs. M. F. Fellows attended the meeting with me. This second year for me was like returning to a college reunion; I knew half of the women from the various states and most of the officers. It was thrilling to meet the old acquaintances and make new friends—to me a very interesting part of these conferences.

During the summer a tentative program was sent to each President asking us to sign up for one of the panels —these dealt with our various work programs. I chose Paramedical Careers. The chairman, Mrs. L. D. Jacobson, of Paramedical Careers and Recruitment Committee, wrote to me and suggested I talk on nursing and

scholarships. Instead of a speech, I prepared the information in skit form.

Each day these panels were given on the various topics; first introduced by a report from the chairman, then carried on by the volunteer presidents. Such as Monday—Legislation, Membership, Bulletin, Today's Health, AMEF, History, Finances and By-Laws. As each panel was announced, the presidents for that panel came forward, and the national chairman presided. Tuesday, there were panels on Program and Community Service, Paramedical Careers, Safety, Civil Defense, and a skit on Parliamentary Procedure. Wednesday—Mental Health was the only panel that the presidents took part in. A clinic on Auxiliary Problems moderated by Dr. Ernest Howard was given. Each national chairman sat up on the stage and we could ask them questions. Films were shown—"The Medicine Man"; "Helping Hands for Julie"; and "Preface to a Life". This type of reporting made the meeting much more interesting and very informative.

All the time was not spent in meetings. On Monday morning we were the guests of the National Auxiliary at a Continental Breakfast in the Hotel. Tuesday morning Mrs. William Mackersie, the Regional Vice President of our North-Central area, called everyone from her area to a breakfast in the Drake Coffee Shop. We all attended and enjoyed meeting our neighbors. Wednesday we ate a hurried breakfast in order to check out, so we would be ready to leave as soon as the meeting adjourned.

MRS. REUBEN F. ERICKSON,
President, State Auxiliary

HENNEPIN COUNTY AUXILIARY ANNOUNCES BENEFIT BRUNCH AND STYLE SHOW

Arrangements have been completed for the Hennepin County Medical Auxiliary's Annual Benefit Brunch and Style Show which will be held April 29-30 at 9:30 a.m. in the Dayton Sky Room.

This outstanding show is produced annually by the Dayton Oval Room, and this year an Oval Room dress and hat will be given away on each of the two days as door prizes. There will also be favors for all who attend.

Tickets at $3.00 are available by writing to Mrs. John P. Wendland, 6512 Parkwood Road, Minneapolis 24, Minnesota.

This occasion is the only fund-raising project of the year for the Hennepin County Auxiliary, and the list of philanthropic projects which benefit is long.

Mrs. Theodore Smith and Mrs. Julian Petit and their committee are in charge of arrangements.

A cordial welcome is extended to all.

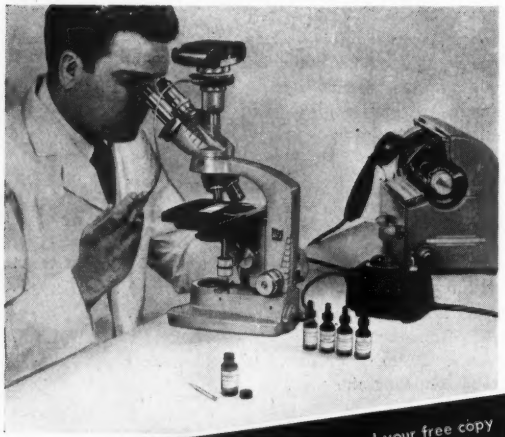
THIRD DISTRICT MEETING HELD

Mrs. I. M. Hauge, Clarkfield, Regional Director of the Third District, called a meeting for the officers of the various auxiliaries in that district for the purpose of working on national reports. The luncheon meeting was held March 31 at Montevideo, Minnesota, and Mrs. Reuben Erickson and Mrs. M. F. Fellows were guests.

STEARNS-BENTON AUXILIARY SPONSORS RECRUIT TEA

The Annual Nurses' Recruitment Tea was held February 18 at the Nurses' Home of the St. Cloud Hospital. Sister Cassian and her nursing class took charge of the hospital tour, film and entertainment, and the Stearns-Benton County Medical Auxiliary served coffee, cookies, candy and nuts.

There were four boys among the 200 students served from St. Cloud and the neighboring communities. The auxiliary has changed the event to a Paramedical Career Recruitment Tea and hopes to interest more students in that way.



ZUMBRO VALLEY AUXILIARY SPONSORS TOUR

At its meeting March 11, the Zumbro Valley Medical Auxiliary enjoyed an educational tour of the new medical science building at Rochester. Mrs. Reuben Erickson, Minneapolis, State President, and Mrs. M. F. Fellows, Duluth, President-Elect, attended. Tea was served following the tour.

ULMER

LABORATORY REAGENTS and stains

New CATALOG

If you haven't already received your free copy of our new 64 page catalog of clinical Reagents and Stains, write for same today. It lists all of the more commonly used laboratory reagents and stains. You will find it very helpful.

ULMER REAGENTS AND STAINS HELP ACHIEVE ACCURACY

It is our objective to produce the finest reagents obtainable for clinical laboratory use. Their consistent accuracy saves hours of the technician's time.

Our scientific laboratory control is your assurance that Ulmer reagents are always fresh and meet the most exacting standards for each procedure. Every step of the manufacturing process is checked from the raw materials to the finished product. Moreover, our chemists are available to assist with any procedures with which you may be experiencing difficulties. Do not hesitate to call on them for assistance or advice.

For prompt and efficient service as well as guaranteed satisfaction, insist on Ulmer Reagents and order them direct from P & H.

In Memoriam

G. DOUGLAS BRAND

Dr. G. Douglas Brand, St. Paul physician, died of a heart attack February 23, 1959, in New Britain, Connecticut. He was sixty-six years of age at the time of his death.

A native of St. Paul, Dr. Brand received his preliminary education at St. Paul Central High School. He attended Northwestern University in Evanston, Illinois, and graduated from Northwestern University Medical School in 1917.

He served in the Army Medical Corps during World War I.

Positions and professional affiliations held by Dr. Brand include: Attending Staff: Ancker Hospital, St. Luke's Hospital, Miller Hospital; Chief of Varicose Vein and Ulcer Clinic, Ancker Hospital.

He is survived by his wife.

BERNARD A. FLESCHE

Dr. Bernard A. Flesche of Lake City, died February 12, 1959. He was fifty-four years old at the time of his death.

Dr. Flesche was born in Walnut Grove, Minnesota, and graduated from Albert Lea High School. His medical education was obtained in the University of Minnesota Medical School.

He was past president of the Lions Club in Lake City, chairman of the Lake City Harvest Festival, past president and secretary of the Wabasha County Medical Society, past president of the Southeastern Minnesota Medical Society, chairman of the Lake City Baseball Club. He was also a member of the Minnesota State Medical Association and the American Medical Association.

At the time of his death, Dr. Flesche was a member of the Gamehaven Council executive board and a representative to the National Boy Scout Council. He was holder of the Silver Beaver Award, which he received in 1954. He was vice president of the Gamehaven Council from 1954-55, and medical doctor of the 1950 Valley Forge National Boy Scout Jamboree.

Survivors include his wife and five children.

WILLIAM B. GRISE

Dr. William B. Grise, a practicing physician in Austin for forty-one out of the forty-four years of his medical career, died February 20, 1959. He was seventy-three years old at the time of his death.

Dr. Grise began his career as a physician in 1915 in Ada, Minnesota. The following year, he moved to Brownsdale until he went to Austin in 1918. Dr. Grise together with Drs. C. F. Lewis, Emory Rebman and C. C. Allen, also deceased, formed the Austin Clinic in 1919. Dr. Grise was past president of the Mower County Medical Society and a staff member of St. Olaf Hospital. He was a member of the Minnesota State

Medical Association and the American Medical Association.

He was graduated from high school in Louisville, Ohio, and attended Adelbert College at Cleveland. He received his Bachelor of Arts degree from Western Reserve University, Cleveland, and graduated from Western Reserve Medical School, Cleveland, in 1914. He was an intern at Miami Valley Hospital, Dayton, Ohio, 1914-15.

He is survived by his wife, a son Robert of Hopkins, and two daughters, Mrs. James Morrow (Jane), Milwaukee; and Mrs. A. Marmesh (Elizabeth), Los Altos, California.

CARL J. LUCKEMEYER

Dr. Carl J. Luckemeyer, St. Cloud physician, died March 13, 1959, at the age of forty-one. Death resulted following a heart attack which he suffered after performing surgery in the St. Cloud Hospital.

Dr. Luckemeyer was president-elect of the Hospital Staff. He also was immediate past president of the St. Cloud Exchange Club and a member of several civic organizations. A member of Stearns-Benton Medical Society, he also was a member of the Minnesota State Medical Association. His medical education was obtained from Marquette University.

Survivors include his wife and three children.

CHARLES A. OLSON

Dr. Charles A. Olson, who had practiced medicine since 1910 on the East Side of St. Paul, died March 18, 1959. He was seventy-one years of age at the time of his death.

Dr. Olson was a native of St. Paul and received his preliminary education at Cleveland School. His medical education was obtained at the University of Minnesota Medical School.

Positions and professional affiliations held by Dr. Olson include membership of the staff of Bethesda Hospital and of the visiting staff of Children's Hospital.

He was a member of the Odd Fellows and Masonic Lodges. In addition, he was a member of the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, Selma; two sons, Robert, rural Rosemount, and Charles L., Lake City, Minn.; a daughter, Mrs. Lee Bittner, Fort Dodge, Iowa; a brother, Elmer, St. Paul, and a sister, Mrs. Harry Nelson, White Bear Lake. There are nine grandchildren.

HARRY LEE PARKER

Dr. Harry Lee Parker, a member of the staff of the Mayo Clinic from 1925 to 1934 and from 1945 to 1959, died March 1, 1959.

Dr. Parker was born in Limerick, Ireland, and received preparatory schooling at the Marish Brothers' School in Johannesburg, South Africa. He received the degree of Bachelor of Arts in 1916 from Trinity College of the University of Dublin, and the degrees of Bachelor of Medicine, Bachelor of Surgery and Bachelor in the Art of Obstetrics from the college in 1918.

Dr. Parker volunteered for service in the Royal Army Medical Corps of England in April, 1918, and he served in France. He came to Rochester, Minnesota, in November, 1919.

He was appointed to the staff of the Mayo Clinic as a consultant in neurology on January 1, 1925, and instructor in neurology in the Mayo Foundation, Graduate School, University of Minnesota. He subsequently was advanced to Assistant Professor and Associate Professor. He left Rochester on August 1, 1934, to return to Ireland, where he practiced neurology and psychiatry in Dublin.

Dr. Parker returned to Rochester in July, 1945, as a consultant in neurology in the Mayo Clinic and Professor of Neurology in the Mayo Foundation. In 1955 he wrote a volume, "Clinical Studies in Neurology," based on lectures he had given to medical students in Dublin.

Dr. Parker received the degree of Doctor of Medicine in 1945 from Trinity College in Dublin, and in 1947 he was certified as a Specialist in Neurology by the American Board of Psychiatry and Neurology, Inc. He was a fellow of the Royal College of Physicians of Ireland and of the Royal Society of Medicine of England, and was a member of the British Medical Association, the Royal Academy of Medicine in Ireland, the Association of British Neurologists, the Minnesota State Medical Association, the American Medical Association, the Central Neuropsychiatric Association, the American Neurological Association, the Minnesota Society of

JACOB SHORT

Dr. Jacob Short, St. Paul physician, died February 18, 1959, in Miami, Florida. He had been in ill health for more than two years and was in Florida on a vacation.

A native of St. Paul, Dr. Short was graduated from the University of Minnesota Medical School in 1926. With the exception of a period of military service in World War II, he was in practice here since leaving school. He was owner of the Northwest Institute of Technology in Minneapolis at the time of his death.

He was a Scottish Rite Mason and belonged to the Ramsey County Medical Society, the Minnesota State Medical Association, the American Medical Association, B'nai B'rith, and Mount Zion Temple, and was a former vice commander of Post 162 Jewish War Veterans.

He is survived by his wife, Bess, a son, Capt. Marshall Short, stationed at Ft. Rucker, Ala.; a brother Philip, and a sister, Mrs. Isadore Bernick, both of St. Paul, and a grandson.

The Physician's Diary

Dr. Peter J. Kitzberger, New Ulm, was elected president of the Brown County Medical Society at the annual meeting held recently in the Dacotah Hotel. Other officers are **Dr. Milton Kaiser,** vice president; and **Dr. Frank Carthey,** secretary-treasurer, both from New Ulm. New members of the society are **Dr. John Sturgis,** Lamberton; **Drs. Francis Boyle** and **John Wohlrabe,** Springfield. **Dr. Charles Tesar,** New Ulm, showed slides on common diseases of the eye and told of their treatment.

* * *

Re-election of **Dr. Reynold P. Flom,** St. Paul, as president of the Twin City Nursing Home Association, has been announced. The organization represents thirty-four nursing homes operating in the Twin City metropolitan area.

* * *

Members of the Mayo Clinic staff attended a number of meetings and institutes throughout the United States and Canada recently. **Drs. O. H. Beahrs, D. O. Ferris, E. S. Judd, J. G. Love,** and **J. M. Waugh** attended the meeting of the Central Surgical Association in Montreal, Canada. Dr. Beahrs presented a paper on "The Treatment of Carcinoma of the Tongue: End Results in 168 Cases," and Dr. Judd presented a paper written with **Drs. J. W. Johnson** and **D. C. Dahlin,** on "Malignant Neoplasms of the Colon and Rectum in Young Persons." **Drs. H. F. Ellis, J. H. Grindlay** and **W. H. ReMine** also attended the meeting. Dr. Ellis presented a paper on "Open Heart Surgery in the Treatment of Acquired Mitral Insufficiency," and Dr. ReMine discussed a paper presented at the meeting. **Dr. G. B. Logan** attended a meeting of the American Academy of Allergy held in Chicago. He also assisted with examinations of the Subboard of Allergy of the American Board of Pediatrics and attended a meeting of the Advisory Council of Allergy. Recently, he took part in a postgraduate course at the University of Texas, Galveston, presenting papers on "Liver Disease in Infancy," "Diagnosis, Pathology and Treatment of Childhood Asthma" and "Use of Steroids in Allergic Diseases in Children." **Dr. G. A. Peters** also attended the meeting of the American Academy of Allergy. A paper, titled "The Treatment of Interatrial Communications," was presented by **Dr. J. W. Kirklin** as part of a course on "Recent Advances in Cardiovascular Disease." The course was held under the auspices of the American College of Physicians and Mount Sinai Hospital, in New York. **Dr. N. G. G. Hepper** attended a meeting of the Minnesota Trudeau Society in St. Paul. He is secretary-treasurer of the organization. Also attending were **Drs. M. B. Divertie** and **H. W. Schmidt.**

* * *

The humor and pathos that flavors the practice of medicine were recalled by **Dr. R. H. Wilson,** Winona, whose practice has spanned thirty-six years, in an address at a recent luncheon meeting of the Winona Kiwanis Club at Hotel Winona. "A doctor," Dr. Wilson observed, "is the first one you see when you come into this world and the last you see when you go out. Between these extremes lie all of the tragedies and comedy of life." A former president of the Minnesota State Medical Association, the son of a doctor and himself a father of a physician, Dr. Wilson reminisced on the "Golden Age of Medicine" and noted the advances in medical techniques and procedures that have been realized in the years since he, as a boy, observed his father in his practice.

* * *

At a meeting of the Kanabec County Hospital Staff recently, **Dr. H. L. Berge,** Mora, was named Chief of Staff by fellow medical staff members. Chosen as Assistant Chief of Staff was **Dr. C. S. Bossert.** Clifford Johnson, Hospital Administrator, was named as secretary-treasurer of the organization. Other staff members are **Drs. Willard Nordman, Edward Burseth, A. C. Peterson and G. S. Lewallen.**

* * *

An annual lectureship in child health and welfare has been provided for by a bequest in the will of the late **Dr. H. F. Helmholz,** it has been announced. It is to be known as the Amberg-Helmholz lectureship and will commemorate the forty-six years that Dr. Helmholz and his colleague, **Dr. Samuel Amberg** worked together in the field of pediatrics. The bequest is for $10,000 and is made to Mayo Association.

* * *

Dr. Wayne C. Rydburg has been elected president of the medical staff at Swedish Hospital, succeeding **J. Harold Schultz, M.D.** Both are from Minneapolis. Other officers include **Dr. Earl C. Hindrikson,** president-elect, and Robert E. Kasper, secretary-treasurer.

* * *

Dr. J. L. Bader, Slayton, was named by the membership to represent the Slayton Toastmasters Club at the area contest to be held in the near future. As Slayton winner, he will compete with winners from Toastmasters organizations from a number of southwestern Minnesota communities.

* * *

Eight Mayo Clinic staff members appeared on programs during the four-day sectional meeting of the American College of Surgeons in St. Louis, recently. The Rochester physicians and their subjects were as follows: **Dr. O. T. Clagett,** "Carcinoma of the Lung"; **Dr. Malcolm B. Dockerty,** panel, "Uses, Problems and Abuses of Frozen Section Diagnosis"; **Dr. F. Henry Ellis, Jr.,** "Use of Extra-corporeal Calculation in the Surgery of Congenital Heart Disease" and panel, "Surgery of Heart Disease"; **Dr. Joseph M. Janes,** "Amputations in Peripheral Vascular Disease"; **Dr. Paul R. Lipscomb,** "Orthopedic Aspects of the Protruded Intervertebral Disc Syndrome"; **Dr. William H. ReMine**

and **Dr. Waltman Walters,** cine clinic, "Cancer of the Stomach, Gastrectomy."

* * *

Official announcement was made recently by **Dr. C. M. Robilliard,** Faribault, of his retirement as a practicing physician. He is now convalescing at his home in Faribault.

* * *

The medical staff at the Rice Memorial Hospital in Willmar, honored **Dr. J. C. Jacobs,** a retired colleague, at a dinner meeting recently. At the testimonial dinner, held at the the Fireside, the honored guest, now retired after more than fifty years of service to this community, was presented with a traveling bag, as a token of esteem and recognition. The presentation of the gift was made by **Dr. R. K. Proeschel,** on behalf of the assembled fellow physicians and surgeons.

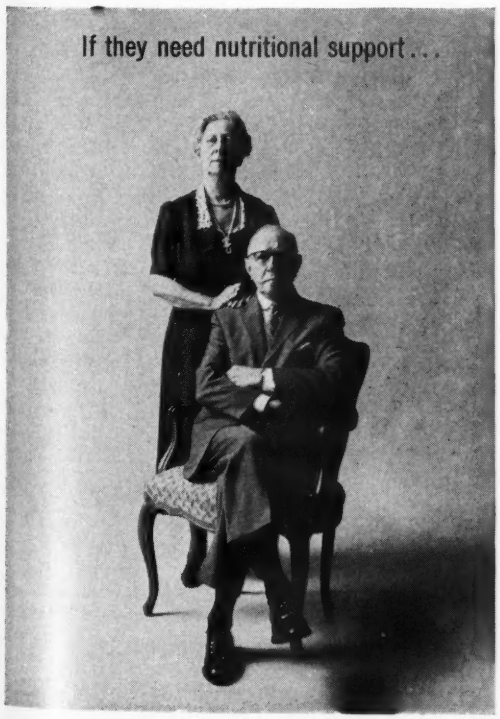
* * *

Drs. E. V. Allen and **Thomas H. Seldon,** Mayo Clinic staff members, were members of a faculty of thirty-three speakers from twenty-two medical schools of the United States who presented papers at the annual clinical conference of the Chicago Medical Society in the Palmer House, Chicago, recently. Nearly 4,000 physicians from the midwest and Canada attended. Dr. Allen's subject was "Natural History of Arteriosclerosis Obliterans," while Dr. Seldon spoke on the topic, "Problem in the Usage of Blood and Fluids in Surgery." Dr. Allen is senior consultant in medicine of the Mayo Clinic and professor of medicine in the Mayo Foundation. Dr. Seldon is consultant in anesthesiology, Mayo Clinic, and associate professor of anesthesiology, Mayo Foundation.

* * *

Dr. Charles W. Alden, Kimball, has moved to new office quarters in the Dingmann Building. The building has been remodeled and made into a modern office with examining rooms, x-ray rooms and all modern facilities.

* * *



Dr. H. T. Petraborg was elected president of Aitkin Community Hospital at the annual reorganizational meeting recently. **Dr. Richard Burman** and **Dr. F. C. Closuit,** both of Aitkin, were elected vice president and secretary-treasurer, respectively.

* * *

Dr. Harold O. Perry and **Dr. Stanley A. Lovestedt** of the Mayo Clinic received the first award for their exhibit, "Lesions of the Oral Mucosa," presented at the 24th annual midwinter clinical session of the Colorado Medical Society held in Denver, recently. Dr. Perry is a consultant in dermatology, Mayo Clinic, and instructor in dermatology, Mayo Foundation. Dr. Lovestedt is head of the section of dentistry, Mayo Clinic, and assistant professor of dentistry, Mayo Foundation.

Dr. Winchell McK. Craig, emeritus head of the Section of Neurologic Surgery of the Mayo Clinic and emeritus professor of neurologic surgery in the Mayo Foundation, Graduate School, University of Minnesota, spoke on the occasion of the presentation of a portrait of the late Dr. Gilbert Christian Anderson to the Louisiana State University School of Medicine in New Orleans on April 1. Dr. Anderson died on June 20, 1948.

Dr. Anderson, a native of Tennessee, came to Rochester on April 1, 1924, as the first fellow of the Mayo Foundation to specialize in neurologic surgery and the first to receive from the University of Minnesota, by way of the Mayo Foundation, the degree of master of

science in surgery with a special emphasis on neurologic surgery. This degree was awarded to him in 1927.

Dr. Anderson left Rochester on July 1, 1927, and entered into the private practice of neurologic surgery in New Orleans. He was one of the founders of the American Board of Neurological Surgery, Inc., and was a charter member of the Harvey Cushing Society. He was a member of the staffs of the Touro Infirmary, the Eye, Ear, Nose and Throat Hospital, the Charity Hospital, the Southern Baptist Hospital, the Hotel Dieu Hospital and the French Hospital, all of New Orleans, and he was assistant professor of surgery in the Louisiana State University Medical Center in that city.

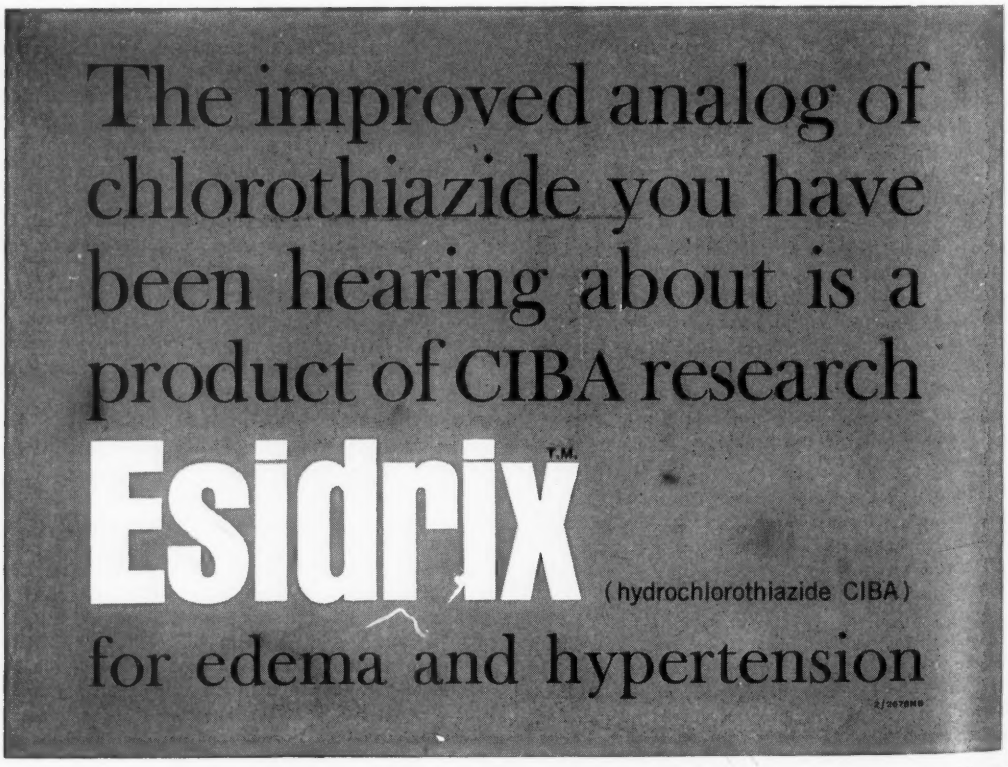
* * *

Ten Minnesota medical scientists have been awarded Heart Fund research fellowships totalling $114,000 for heart and blood vessel disease studies during the year beginning July 1, 1959.

Dr. Karl W. Anderson, president of the Minnesota Heart Association, identified the recipients as: Drs. Richard A. DeWall, Anastasius Dontas, Victor Lorber, Edward Ronwin, Alan P. Thal, Naip Tuna, Robert L. Vernier, Lewis W. Wannamaker, and Warren J. Warwick, all of the University of Minnesota, and Dr. James J. Peifer, Hormel Institute, Austin, Minnesota.

The $114,000 national grant was Minnesota's share of $1,562,243 given on March 25 to 182 scientists in twenty-eight states and two foreign countries by the American Heart Association.

The awards represent the first part of the 1959-60 national research support program sponsored jointly by AHA and affiliated Heart Associations.



National research grants returned to Minnesota scientists, said Dr. Anderson, have consistently exceeded the amount of Heart Fund dollars sent to national headquarters from this state, because of the outstanding research facilities and people existing in Minnesota.

The Management of Emotional Stress in the Housewife

● **Consider the housewife in her house: she toils, she weeps, and she has pain. This paper emphasizes the importance of stress as a cause of symptoms in housewives. The author points out the value of early recognition by the family physician of these psychiatric implications. Psychiatric first aid by the family physician often can obviate later, more complicated psychotherapy.**

ROBERT L. FAUCETT, M.D.
Rochester, Minnesota

THE COVERAGE of this title is so broad, in respect to the condition mentioned and also to the group of patients suffering from the condition, that some clarification is needed. First, a definition of the patient: The term *housewife* shall be used to represent the worker in that most difficult of all occupations which is really a multiplicity of occupations, including companion, mother, sexual partner, cook, homemaker, hostess, chauffeur, financier, citizen, teacher, and often auxiliary breadwinner. The difficulty of this multiplicity

Read at the Clinical Session of the American Medical Association, Minneapolis, Minnesota, December 2 to 5, 1958.

From the Section of Psychiatry, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

of roles is accentuated by the fact that the occupation of housewife is not held in high esteem, or at best does not provide prestige in our culture commensurate with its arduousness and value. This, when added to the fact that many women have been carefully taught in childhood that womanhood is a state to be abhorred, makes it a minor miracle that not all housewives exhibit overt symptoms of emotional stress.

But to describe a pathologic condition in terms of a total population is impractical. Emotional stress will be considered here as those combinations of overtaxing of capacity, insufficient gratification, and inability to accept the feminine role which lead to the development of symptoms which bring the victim to consult a physician. This situation is likely to be chronic or subacute. The symptoms may be exclusively somatic; or whatever their type, they may not be recognized or accepted by the patient as related to the interpersonal or environmental stresses of living; and they may not be incapacitating enough to cause hospitalization if psychiatric referral is not necessary or available.

Dealing With the Housewife's Stress in General

The fundamentals of managing these reactions are essentially the same as in other aspects of medicine, namely the eliciting of the history, the detection of the events in the history which have relevance to the emotional disturbance, the sharing with the patient of the reasons for the conclusions drawn, and the presentation of alternatives for the amelioration of the problem.

Difficulties.—There are two problems which tend to make this procedure more difficult. From the start, most physicians have been trained to study breakdowns or disorders of the human as aberrations of a physicochemical machine rather than as responses of a psychosocial organism. Many physicians thus hesitate and even refuse to venture into fields where they do not feel competent, although psychosocial data are not mysterious and often lend themselves to commonsense logic once enough facts have been collected and interpreted. (Sometimes, however, attempts are made to manage without this step.)

The second difficulty is shared by physician and patient. In the case of physicochemical breakdown the primary therapeutic effort is in the activity of the physician, and the patient's responsibility is less. In the case of psychosocial breakdown the emphasis is reversed and the patient must accept responsibility for making changes in her life situation to restore equilibrium. Patients naturally are reluctant to undertake the burden of the cure, and many physicians are reluctant to part with their prerogatives as magical medicine men.

Positive Principles.—Obviously a thorough discussion of technique is impossible here, but several principles and pitfalls in the management of this situation can be mentioned.

Medical Study.—Even if the symptoms seem clearly emotional, a careful medical history and examination with indicated laboratory work are indispensable. It is surprising how many organic illnesses in the early phases elicit symptoms of anxiety, fatigue, depression, and somatic concern which may sound hypochondriacal. This is especially true of diseases of organs of internal secretion before localizing symptoms have developed, for the patient has a vague but distressing feeling that something is wrong and because of the vagueness describes it in bizarre terms.

Report of Cases

Case 1.—A married woman, aged forty-two, came complaining of lethargy, fatigue, insomnia, anorexia, constipation, amenorrhea, and inability to concentrate. She had been referred for electroshock treatment after a medical consultation at home. She described episodes of forgetfulness of recent events in a peculiarly humorous fashion and described herself as "comical." No self-depreciation or feeling of guilt was elicited, however. Medical and laboratory examinations revealed myxedema with a basal metabolic rate of —39 per cent and a value of 1.0 microgram of protein-bound iodine per 100 ml. of blood. She was treated with thyroid extract, and the symptoms of myxedema disappeared. Her psychiatric symptoms remained only slightly improved; but since such symptoms are often the last to disappear in myxedema, a period of watchful waiting was decided upon.

The patient was seen eight months later and was judged to be euthyroid. The basal metabolic rate was —3 per cent, and the value for protein-bound iodine was 4.6 micrograms. She still complained of anorexia, lack of interest in home or family, and crying spells; and, although she was less forgetful, she still had trouble thinking and calculating. The psychiatrist was

impressed again by the lack of guilty self-depreciation; as the patient expressed it, "I worry because I do not worry about my situation enough." She had expressed anxiety about going down stairs and admitted to have fallen once. She had awakened on several occasions with uncontrollable swallowing movements. She insisted that there was something organically wrong with her and that her difficulties were not on a functional basis. Psychologic testing showed organic confusion. An electroencephalogram disclosed a dysrhythmia, grade 2, localized in the right parieto-occipital region. Pneumoencephalography revealed a communicating porencephalous cyst in this region. No surgical treatment was recommended.

Although nothing could be done to alleviate her symptoms, the patient was glad to have had her own diagnosis confirmed and to be absolved of "neurotic complaining." Modification of environmental responsibilities left her functioning well at a level within her capabilities.

Opening of Psychosocial Inquiry.—After medical examination has failed to produce a diagnosis, the physician may suggest that the presenting symptoms could be due to environmental stress, and offer opportunity to discuss it. Such inquiry should be preceded by reassurances that this does not mean the patient is crazy or weak or blameworthy. Some resistance may be met, in which case the patient must be allowed to decide whether she wishes to explore this aspect of the situation. Cajoling, scolding, and insistence have no place here. No patient can provide data relevant to any kind of illness without wholehearted co-operation and wish to get well. It must be remembered that frequently patients visit a physician not to be healed but to get some secret and often subconscious gratification out of frustrating him.

Physician's Interest.—The patient must be made to feel that the physician is as interested in hearing this material as he was in hearing the description of the somatic symptoms. Any physician who cannot muster interest in this aspect of illness cannot manage the situation adequately and should consider referral to a colleague who can.

Interviewing Others Involved.—The advantage of interviewing other persons involved in the situation should always be considered. Frequently this will open avenues of communication previously not utilized by the patient in the sharing of her burdens.

Interpretation of Data.—Some attempt at summing up the data must be made. Emphasis must be placed continually on the environmental problems to be solved; and use of phrases like "it's your nerves," "chronic nervous exhaustion," and so on should be avoided. These phrases refer to the physicochemical machine and encourage the patient to continue focusing on her organic system.

Presentation of Alternatives.—It must never be forgotten that the physician's function should be to delineate the problem and if possible present the patient with alternatives. One of the alternatives must always be that the patient can continue as before. Usually it is the physician's role to help the patient help herself rather than to attempt to solve the problem for her.

Case 2.—A forty-five-year-old woman came to the clinic complaining of pain in the rectum of twenty-five years' duration. For the three years prior to her registration this pain had become so severe as to be incapacitating. Roentgenologic and proctoscopic examinations gave no explanation. The internist called the psychiatrist and said that unfortunately he knew less about the patient than he did about her rectum, but that she had mentioned that her husband was cruel and inconsiderate. The psychiatrist began the interview by saying, "I understand your husband is something of a pain to you."

The patient, whose plans required her to return to her distant home the next day, inquired how long the interview would last. On being told that the psychiatrist had twenty minutes at her disposal, she told the following story.

Her mother had died at the patient's birth, and the patient had been reared by an aunt who inculcated a feeling of guilt for the mother's death by innumerable references to the gratitude the patient should feel for the aunt's "generosity." The aunt exploited the guilt by almost making a slave of the girl. At the age of sixteen years, during an absence of the aunt and uncle, the patient was seduced, with the help of wine, by an uncouth and untutored hired hand, causing her considerable pain and increasing her sense of guilt. When she told the aunt about it in a tearful plea for sympathy, the aunt insisted that the only course was marriage—obviously to get rid of her. The girl acquiesced, and she had continued in this marriage for twenty-nine years with rage bound by guilt. She had tolerated it only because of guilt and masochistic needs.

At the end of the recital the patient said she could see the relationship of her rectal pain to her life history, and she asked what she should do. The psychiatrist offered three courses: (1) to continue as before, (2) to leave the husband, or (3) to express

feelings directly and openly instead of in physical symptoms. She begged him to choose, but he demurred. In a letter received several months later the patient wrote, "My pain is gone; I didn't leave him, but he doesn't like it." This result was achieved by devoting twenty minutes to the patient's life situation.

Offer of Continued Help.—The physician may indicate continuing interest and willingness to see the patient regularly, even for brief periods, provided he makes it understood that the time is to be used purposefully for further clarifying the patient's life situation.

Pitfalls.—There are some corollary pitfalls to be avoided.

Hasty conclusions that the trouble is emotional in nature. Even if this is the case, the patient's confidence and rapport are increased by a careful attention to the medical examination.

Anxiety and impatience in the physician. If these feelings are present, the physician's awareness that he has them should help him avoid the prescription of sedatives, vitamins, unnecessary laboratory examination, and so on merely as a way of lessening his own discomfort.

Overidentification with the patient or acceptance of her rationalizations. The description of the situation may be distorted by the patient's need to project the difficulty elsewhere so she may avoid facing her responsibilities in it. This is frequently the case where the personality and behavior of the husband are alleged to be the source of the stress. It may be so, but such statements cannot be taken at face value without giving the husband equal time.

Giving advice categorically rather than offering tentative suggestions. Advised categorically, the patient has to accept the advice or break off the relationship with the physician. Tentative suggestions avoid this dilemma, and can open more areas of information by the discussion they stimulate.

Practicing magic—the use of placebos, suggestion, or such nonsense as "why don't you just relax," "stop worrying," and the like. If the patient could do this she would not have visited the physician in the first place.

Comment.—If the request of the patient for help is evaded—or if any other course than facing the facts and eliciting the data about social history and circumstances is followed—many untoward consequences can ensue. If the patient's difficulties are ignored or an attempt is made to manage by physicochemical methods or without collection of psychosocial data and use of psychosocial methods, an impasse arises.

The application of knowledge derived from study of the person as a physicochemical machine is not successful in solving problems of interpersonal relationships. Yet the expectation of magical solutions to psychosocial problems by application of physicochemical methods is increased and perpetuated in the patient population. I suspect that this exaggerated expectation accounts for a large degree of the increasing dissatisfaction with and derogation of the medical profession as a whole in the face of marvelous advances in technical knowledge and skill in relieving physicochemical breakdowns such as have been reported at this meeting.

The physician's acceptance of the total responsibility to "make the patient well" by suggestion, surgery, or sleeping pills does not educate her or point out to her the source of her difficulties. Conversely, it does prevent her from accepting some responsibility for her distress and its relief. As long as her attention is focused on her organic system as the seat of the difficulty, she can do nothing to help herself against the menace in the psychosocial realm.

Furthermore, she may suffer from secondary complications of the attempt to cure her by repair of the machine or by giving medicaments. Her confidence in physicians, and their respect for her, may suffer so that when a structual illness supervenes she is denied the full benefits of modern medical skill by her unwillingness to see a physician or by his preconceived notions of the nature of her trouble.

The complication of financial stress also may increase her troubles.

Management of Acute Stress

Another type of stress I should like to discuss briefly is the acute type brought about by loss or the threat of loss—whether personal, as in bereavement, or material—or by sudden disabling illness, or by any form of necessity for changes in the place or mode of living. In his studies of psychologic reactions to civilian disasters, Tyhurst[1] has referred to these as "transition" states.

For several reasons, it is important to have an understanding of the nature and handling of these transition states.

First, the way in which reaction to catastrophe is handled determines to a large extent whether this event will be a constructive bridge to a satisfactory adjustment to a changed way of life in the future or will be borne as a cross, with a martyred, resentful attitude and all its regressive and destructive features that bind the victim to the past so firmly that future growth is impossible. In addition, this method of dealing with catastrophe may be thus transmitted to the children in the family, and their growth likewise hampered by it.

Second, physicians frequently are in a position to administer psychiatric first aid in situations involving death or severe illness of spouse, parent, or child, and to perform a valuable function in preventive psychiatry and avoidance of emotional illness in the future. The physician in this role appears to me to be the most profitable agency now available to preventive psychiatry.

Because the psychologic dynamics and principles of management are essentially the same for all acute disruptions of emotional relationships and modes of living, the situation caused by the death of a husband may serve as a prototype.

What is to be discussed here has been derived from wartime experiences, from Tyhurst's[1] study of reaction to civilian disaster, and from psychiatric experiences in working with unhealthy reactions to catastrophe.

Reactions to such a catastrophe can be divided into three parts:

The Period of Impact.—This is the period when the impact of initial stress exists, when the imminence or occurrence of death is recognized, and when all the details of dealing with it preoccupy the victim's mind. About 12 to 25 per cent of persons in this situation react with coolness and collected behavior; about 70 per cent are stunned and bewildered; and about 10 to 25 per cent show manifestly inappropriate responses—states of confusion, paralyzing anxiety, inability to move out of bed, hysterical crying and screaming, or outbursts of angry vituperation even toward the dead person. Usually this period is brief, a matter of a few hours. The reactions within it are not crucial to future adjustment. Sedatives may be indicated, but intervention is not.

The Period of Recoil.—There follows a gradual return of self-consciousness and awareness of the immediate past as well as of the nature of the emotional relationship that has been disrupted. This is the crucial phase in the grief reaction, and future emotional health depends on its being properly worked through. For the majority of people the first overt emotional expression occurs in this phase. There is a great need to talk and ventilate feelings about the one who is dead. This need to ventilate—to cry, to be angry, to talk about the past—must be encouraged. The bereaved one needs to recall the unpleasant as well as pleasant aspects of the relationship. This emotional ventilation is necessary in order for the victim to begin to relinquish the emotional investment and to free energy for future constructive emotional relationships. For reasons that cannot be included here our society has discouraged this ventilation. The bereaved one who is "brave," keeps a "stiff upper lip," "holds up well" is praised. Mothers refuse to grieve "for the sake of the children," who also need to grieve and need her acceptance of this expression.

Accompanying this need to ventilate is a childlike dependence, a need to be taken care of. More important than the tokens of being taken care of is the psychologic significance of being cared for.

Religious rituals such as wakes and other emotion-charged rites serve these purposes well, but now are indulged in by a minority of the population. A physician, however, with his aura of authority and tradition of caretaking, can be a very significant figure in encouraging an appropriate expression of the grief reaction rather than participating in its suppression for reasons of social approbation.

Lindemann[2] has provided an accurate description of persons in this state.

> Common to all is the following syndrome: sensations of somatic distress occurring in waves lasting from twenty minutes to an hour at a time, a feeling of tightness in the throat, choking with shortness of breath, need for sighing, and an empty feeling in the abdomen, lack of muscular power, and an intense subjective distress described as tension or mental pain. . . .
>
> The sensorium is generally somewhat altered. There is commonly a slight sense of unreality, a feeling of

increased emotional distance from other people (sometimes they appear shadowy or small), and there is intense preoccupation with the image of the deceased. . . .

Another strong preoccupation is with feelings of guilt.

In addition, there is often disconcerting loss of warmth in relationship to other people, a tendency to respond with irritability and anger, a wish not to be bothered by others at a time when friends and relatives make a special effort to keep up friendly relationships. . . .

The activity throughout the day of the severely bereaved person shows remarkable change. . . . There is restlessness, inability to sit still, moving about in an aimless fashion, continually searching for something to do. . . .

These five points—(1) somatic distress, (2) preoccupation with the image of the deceased, (3) guilt, (4) hostile reaction, and (5) loss of patterns of conduct—seem to be pathognomonic for grief.

These symptoms and signs of disturbed psychologic functioning must be regarded as normal for a person in the situation assumed, and their absence may be an ominous sign for that person's future health. Our tendency to regard symptoms invariably as signs of illness requiring elimination needs to be revised in this instance. We should think of the transition state as setting the stage for an opportunity for growth.

It is in this stage of recoil that intervention by the physician is indicated. The nature of the intervention is too detailed for presentation here, but a few principles can be mentioned.

1. The patient should not be removed from her situation—geographically, socially, or emotionally. Sedatives and tranquilizers should be used sparingly, and only in situations where the turmoil is intolerable.

2. The physician must accept disordered affect, irrational attitudes, and negative responses in a nonjudicial way and encourage friends and relatives to do likewise. The reaction needs to run its course and not to be suppressed.

3. The activity of the persons involved needs to be great. Acceptance and presence are needed more than active reassurance.

4. A major effort is needed to prevent development of a feeling of discontinuity between past, present, and future. The event must be made a bridge between past and future, and the person must be encouraged to reconstruct the past in relation to the present, even in the face of continuing emotional outbreaks and the beginnings of realistic contemplation of the future. It is important that children, if involved, be given the same opportunity.

This phase is of variable length and its subsidence is gradual, but a duration of seven to ten days should not be considered abnormal. Probably the most important part is the emotional ventilation—which is the part that, in general, our culture most tends to suppress.

The Period of Social Reconstruction.—The period following the phase of recoil is the time of social reconstruction; and if the second phase has been worked through properly, the bereaved person is able to utilize to the fullest extent the social forces around her to reconstruct a social role without undue emotional flattening or clinging to the ways of the past or to wishes for them. This is the period of rehabilitation.

Comment.—If the grief reaction is not worked through, it may subside into a condition of chronic tension or depression or guilty preoccupation that will require definitive psychiatric intervention. If this is necessary, it is much more difficult than the thoughtful and courageous psychiatric first aid that might have obviated it at the time of the catastrophe. Psychiatrists have struggled hours on end to achieve a resolution of delayed grief reactions in depressed, dependent, self-pitying individuals in whom the same result could have been achieved by a brief effort at the time of the catastrophe.

The Child with Strabismus

The "cockeyed" child, often exposed to ridicule, may suffer serious psychic scars as well as permanent loss of vision if his condition is neglected. The author stresses the role of the family physician in early recognition of ocular deviation.

JOHN A. DYER, M.D.
Rochester, Minnesota

THE PROBLEM of strabismus is becoming increasingly important to all of us as physicians, since we are confronted more and more with the tiny patient whose parents are distraught because of some abnormality in his ocular movements. Articles in lay magazines and newspapers are causing an increasing awareness of the importance of early diagnosis and treatment of any bodily infirmity, and certainly strabismus is not the least of these, since its early recognition and treatment are of paramount importance.

The child at school age who has evident strabismus has two strikes against him, because he not only looks different from his classmates but also he may act abnormally because he is aware of this difference. Ridicule by playmates is frequent, and this may produce psychologic difficulties of which the parents are completely unaware. To witness the profoundly beneficial effect of treatment on the appearance and personality of the child, as well as on the attitude of the worried parents, is in itself sufficient evidence to convince one of the necessity for early treatment.

This general discussion is concerned with the mechanisms by which strabismus may occur, the available methods of treatment, the role of heredity in such cases, and the extremely important role played by the family physician in the recognition of this deformity. Several questions of interest to both physicians and parents will be discussed.

Mechanisms of Strabismus

The eyes at birth are small, as are the other members of the body; being small, they are hyperopic, or "far-sighted." Since the retinal nerve cells are not fully developed for many months, the newborn cannot see clearly, and the eyes tend to wander rather freely. When the child is three or four months of age, the fovea, or area for central vision, is developing, and the child begins to look at large objects located more by feel than by actual focusing of the eyes. At six months of age, the eyes should be functioning rather well as a team, and this ability for binocular coordination (fusion) should be well established at the age of twelve to fifteen months. The ability of the eyes to accommodate, or focus, so that objects may be seen clearly, develops somewhat more rapidly than does visual acuity; by the age of two or three years, however, both have attained a relatively mature state. To permit perception of an object near at hand as a single image, the eyes must converge as accommodation occurs, and these functions are closely related physiologically. If a child has eyes that are unusually "far-sighted," an excessive amount of accommodation is required to obtain a clear image, and excessive convergence results.

Therefore, any hindrance to the development of normal vision or a requirement for undue work by the accommodative mechanism can set the stage for failure of the eyes to work as a team, thus leading to strabismus. Abnormal deviation of the eyes may be present in different forms and arise from a variety of causes. Most frequently, there is convergent strabismus (esotropia) or divergent strabismus (exotropia), and either type may be constant or intermittent. Vertical deviations occur less frequently.

The ophthalmologist frequently sees an infant whose eyes appear to turn in excessively when he glances to one side or the other. Examination by means of pupillary light reflexes reveals the eyes to be perfectly straight, the cause of the apparent squint being the broad epicanthal folds (frequently noted before the bridge of the nose develops) behind which the eye is hidden. The possibility that actual deviation is present at times should not be discounted too readily, however; follow-up examinations are often required.

From the Section of Ophthalmology, Mayo Clinic, Rochester, Minnesota.

Any actual deviation of the eyes from a parallel position is an indication for a thorough ophthalmologic examination to determine the possible cause, especially in those instances in which the squint is present at birth or develops shortly thereafter. Several questions come to mind. Is the condition the result of some congenital defect of the external ocular muscles or the result of an injury during delivery? Is there some intraocular defect of a congenital nature, or has a tumor of the eye produced a visual deficit and hence the strabismus? Perhaps there is evidence of choked disk, signaling the presence of some abnormal intracranial process. All of these possibilities must be eliminated before the diagnosis of strabismus resulting from some simpler cause is made. Fortunately, the majority of these patients have no other serious defects.

Convergent Strabismus (Esotropia)

More frequently, the tendency to convergent deviation does not become evident until one, two or even three years of age. At first, the deviation may be intermittent when the child is tired, ill or angry, but often it becomes constant. Should the vision remain equally good in each eye, the result probably will be an alternating type of esotropia that persists until some type of treatment is instituted. In many instances, one eye deviates constantly. In order to prevent confusion or diplopia, the brain suppresses the image from the convergent eye and, if the deviation is left uncorrected, deep suppression, or amblyopia, develops. If amblyopia remains past the age of six years, permanently reduced central acuity results in most instances. This reduction of visual acuity (usually 20/200 or less) is commensurate with industrial blindness and could be a great handicap to one desiring a skilled position in industry or aviation, or in a profession that requires excellent binocular vision.

Those patients who have convergent strabismus from birth or shortly thereafter usually require surgical correction. If one eye converges constantly, it is probable that the vision is reduced through suppression, and the other eye must be totally occluded for a time to ensure the development of equal vision in the two eyes before any surgical intervention is undertaken. Any large degree of hyperopia found by cycloplegic refraction also should be corrected by spectacles to determine the effect on the amount of deviation prior to operation. If benefit is not derived from this conservative treatment, an operation is in order. In this type of patient, unusually heavy check ligaments or muscular adhesions often are found that may have prevented the eyes from being straight.

In most instances, the age of onset of esotropia is about two or three years, the period at which visual acuity and accommodation reach a useful level. Since a child's world is nearby, excessive hyperopia requires additional accommodation, and nature's method of solving the confusing problem of balancing the simultaneous excessive convergence is to permit the less dominant eye to turn in. This is termed "accommodative esotropia," and it is the type best suited to conservative treatment. In the majority of patients with intermittent or alternating esotropia beginning at this age, an abnormal degree of hyperopia is discovered by cycloplegic refraction, and the full correction by spectacles often results in normal alignment of the eyes, since there is no longer an excessive stimulus for accommodation and convergence. If one eye turns constantly, equal vision must be regained through occlusion. Should some degree of squint remain after a period of conservative treatment, surgical treatment to correct only this residual deviation is in order.

Divergent Strabismus (Exotropia)

Divergent strabismus, or exotropia, although less frequently encountered in children, is nonetheless a defect that is usually amenable to early treatment. This type of divergence also may be intermittent or constant, but it is intermittent in the majority of cases. The age of onset is variable, ranging from birth to several years but averaging two to five years. The constant type is more commonly noted at an extremely early age, and these children seldom exhibit development of fusion if treatment is not instituted. Patients with intermittent divergence frequently have the common symptom of extreme sensitivity to sunlight, and the parents may note that the child closes one eye or shields his eyes when he is out of doors. In this type, the eyes tend to diverge more as the patient looks at a distance than when he looks at near objects, and there may be poor binocular function for distance but excellent fusion for near vision. The reason for

this is not completely understood but probably it is related to the greater accommodation and convergence required for near vision.

In either the constant or intermittent type of exotropia, conservative treatment is usually of little value. A lens correction for existing hyperopia aggravates the tendency to divergence, while correction of any myopia may improve it. If constant exotropia is present, surgical treatment to gain parallelism of the eyes should be performed as early as feasible, and certainly before the age of six years, if binocular function is to be attained. Although intermittent exotropia usually requires a somewhat different surgical approach, early intervention is still essential, since the intermittent tendency gradually becomes constant.

The surgical treatment of intermittent exotropia is particularly gratifying, since reduction of the tendency to divergence is the usual result, and the fusion mechanism secures a foothold.

Actual training of binocular coordination as a conservative means of treatment enhances fusion ability (if some is already present) in some patients, but it does not alter appreciably the amount of deviation, whether convergent or divergent. It is probably most useful in patients with the divergent type of strabismus to improve convergence ability and fusion after operation.

Comment

The following questions are frequently raised and warrant some discussion. Who is qualified to examine and treat children with strabismus? Only the physician who is specifically trained in ophthalmology and ophthalmic surgery should do so. Treatment by nonmedical personnel is not warranted or advisable. How early should treatment of strabismus be instituted? The best time is just as soon as the deviation is noted. Even at six months of age, it is possible to determine whether or not a squint is present in most cases; if so, some form of treatment can be started. Actual occlusion of one eye, and it must be total occlusion by means of a patch over the eye, may be started satisfactorily by the age of twelve to eighteen months. Frequent examinations are essential during the period of occlusion to be certain that the occluded eye is not becoming amblyopic. By eighteen months, a child with a refractive error will accept glasses readily, and they should be worn during all waking hours. Glasses and occlusion often are used together. Once equal vision is established and glasses have been tried, an operation may be performed to correct the remaining squint; should other means of treatment not be found necessary, surgical intervention may be used to correct all of the squint. Although opinions among ophthalmic surgeons vary as to the earliest age for operation for strabismus, most agree that it is imperative to have proper alignment of the eyes before school age if the child is to have an opportunity to develop fusion.

What is the goal of surgical treatment? It is principally to obtain parallelism of the eyes plus binocular function when conservative means of treatment have not sufficed or are deemed unnecessary. A good cosmetic result is gratifying, but one must strive also for the perfect result of fusion in daily life. Early treatment is the key to successful treatment; the concept, "leave him alone and he will outgrow it," is ill advised.

Many parents are extremely anxious to know how long their child will have to wear glasses. The only honest answer is just as long as they are needed to aid in acquiring and maintaining straight and normally functioning eyes.

The question of heredity in strabismus arises frequently. It is doubtlessly true that both exotropic and esotropic persons are found in succeeding generations when a family history of squint is present. The descendancy is sporadic, however, and not easily predicted. The accommodative type of esotropia is the variety most frequently encountered on a hereditary basis, although it is often difficult to obtain a family history from reluctant parents, who much prefer to blame their child's squint on some childhood disease or injury.

Conclusion

From this discussion, it is evident that a primary requisite in the treatment of strabismus in children is early diagnosis. Here, the family physician plays a most important role, since often he is the first to be consulted by the parents. Patients in whom the diagnosis is doubtful, as well as those who have obvious defects, should be thoroughly investigated. Every physician must be alert to this frequently occurring problem, so that preservation of sight and a properly functioning team of eyes may give those children with strabismus the same advantages enjoyed by those without a similar defect.

Surgery in Cardiac Patients

Major surgery in a cardiac patient is not an infrequent occurrence in these days of increased longevity and improved medical and surgical care. Here, the author gives criteria for establishing whether or not a patient is a good surgical risk and offers guidance for preoperative and postoperative care and the choice of anesthesia for surgery in cardiac patients.

THE CONSTANTLY increasing average age of our population and the natural increase in degenerative heart disease, coupled with better surgical techniques, improved anesthesia, and effective antibiotic therapy, have brought about a situation where major surgery in a cardiac patient is a very common occurrence.

Whereas infections such as pneumonia previously proved to be the "friend of the aged," these patients are now cured by antibiotics and live on; whereas intestinal obstruction carried a high mortality in the past, nasal suction, antibiotics and better ionic control have kept the patient alive. Inasmuch as about 85 per cent of the men in this country at the age of fifty have some coronary disease, it becomes obvious that situations will arise which will necessitate surgery in patients not only with asymptomatic coronary disease but in those patients with either cardiac failure or myocardial infarction. It is estimated that at least 750,000 persons with new cases of coronary thrombosis recover each year and attempt to go back to work. These individuals will develop the usual surgical conditions in the same proportion as normal individuals.

In the past, surgery in cardiac patients carried a very high mortality. Sprague[1] found a mortality of 13 per cent in 170 cases. Butler, Feeney and Levine[2] found a mortality of 6.3 per cent unexpected deaths. Hickman, Livingstone and Davies[3] found 1.7 per cent deaths in 345 operations. Brumm and Willius[4] found a mortality of 4.3 per cent in 259 cases. Morrison[5] found 9.9 per cent mortality in 311 cases, while Hannigan[6] found 5.2 per cent mortality in fifty-eight cases. Baker, Grismer and Wise[7] found a mortality of 5.7 per cent in cases with healed myocardial infarction—the mortality in acute infarction ranging from 50 to 80 per cent. It is interesting as one reads the literature to find that those statistics which were reported ten or fifteen years ago carried a higher mortality than those from more recent years.

In order to determine the present situation, the records of St. Barnabas Hospital (Minneapolis), were compiled for one year. Five types of surgery were selected for this report, namely, cholecystectomy, gastric resection, prostatic resection, hysterectomy, and open reduction of hip fractures. In order to be certain that we were dealing with patients with a very high probability of having coronary disease, only those over the age of sixty were included. There were thirty-three cholecystectomies in this series with two deaths both due to infection. There were twenty gastric resections with two deaths, one due to coronary thrombosis and the other due to unknown causes. Of thirty-

gery rdiac Patients

ARTHUR C. KERKHOF, M.D.
Minneapolis, Minnesota

five prostatic resections, there was only one fatality, and this was due to pulmonary embolism of unknown cause. There were twelve hysterectomies with no deaths. There were thirty-one open reductions of the hip with no cardiac deaths, with one death due to pulmonary embolism as a result of phlebitis. Two patients in this series died of cerebral vascular disease later while in the hospital but not immediately after surgery. Therefore, of 131 patients, there was one death, or 0.76 per cent, due to a known cardiac cause. There was one death, or 0.76 per cent, due to unknown cause, and two deaths, or 1.52 per cent, due to pulmonary embolism. If we assume that all of these were on a cardiac basis, the mortality still would only be 3 per cent. Assuming that at least 85 per cent of these patients had coronary disease, the cardiac mortality amongst those would be only 0.9 or 1 per cent as a certainty, and 3.6 per cent as an outside possibility if we included the cases of pulmonary embolism and the death from unknown causes.

Before going further in the selection of cardiac patients for surgery, it might be well to have a look at what we know of the extra work entailed for the heart in anesthesia. Actually this data is very difficult to obtain on a scientific basis. It would appear that the oxygen consumption is not much elevated by anesthesia, and the work of the heart is closely correlated to oxygen consumption. To be sure, there are increased work factors produced by certain positional changes of the heart and great vessels. Also, the draping of the patient during surgery will necessitate an increased blood flow through the skin required to lower the body temperature. This increases cardiac output. From a practical standpoint it would seem that the work of the heart during surgery is no more than that which is incurred when the patient is up walking around.

My first contact with the problem occurred about twenty-five years ago. For some reason no longer remembered, the surgical service at the Minneapolis General Hospital suddenly began to ask for cardiac evaluation prior to surgery. This was understandable in cases of elderly persons or in known cardiacs. It became rather obnoxious when requested in young individuals with no shred of evidence for heart disease. Even more discouraging was the fact that due to oversight on the part of an ambitious surgical resident these consultations were frequently requested at unreasonable hours such as 11:00 p.m. prior to an 8:00 a.m. surgical case—that patient having been in the hospital for days waiting to get on the schedule. It was then that the medical consultant needed some protection from unnecessary consultations, and we usually ended our consultation with the words, "This patient will have no difficulty in good surgical hands." Despite the facetious tone of this statement at the time, it still tells the story. The good surgeon will have the cardiac status of his elderly or known cardiac patient evaluated, but even more than that, he will listen to the advice of his consultant concerning the preoperative and postoperative care.

The examination to determine the cardiac status need not be elaborate. Above all, a good history in itself will solve many of the problems. If a patient gives no history of anginal pain, dyspnea on exertion or edema, then his functional capacity is usually very high and he should have no difficulty under ordinary conditions of anesthesia or surgery. Even if a history of dyspnea, angina

or edema is present, as long as the individual can walk a few blocks or climb one flight of stairs at a walk, the chances are high that he will not have difficulty in surgery.

The history of a hypertension causes great concern among surgeons. I personally am not at all alarmed by such a history as long as the functional capacity seems adequate. To be sure, the presence of hypertension carries with it a high percentage of coronary disease; but again, if the function is adequate, this will cause no trouble.

A history of rheumatic fever or chorea, although interesting, is not a great factor unless valvular disease exists, and then only under certain conditions.

Examination of the heart for the evaluation is simple. X-ray examinations of the chest reveal cardiac size. The actual measurement of the transverse diameter can then be compared with the predicted transverse diameter from the Ungerleider and Clark Tables to determine whether or not the heart is enlarged. Any transverse diameter more than 10 per cent above the predicted value is considered to indicate cardiac enlargement. Although theoretically not correct, for the practical purposes of this discussion, we may assume that a heart is normal in size whose transverse diameter is less than 50 per cent of the transverse diameter of the chest. Heart failure will occur only rarely in hearts normal in size, the most notable exception being acretia cordis. If the heart is over 50 per cent of the chest diameter, it may be enlarged. In some circles, such enlargement is considered cardiac failure even though actual signs of congestion are absent, and in those circles this so-called compensated failure will require digitalization. I, personally, would be prone to await developments before digitalizing a minimal cardiac enlargement without failure but can find no fault with those otherwise inclined. In these days of rapid intravenous digitalization, I feel that we are perfectly able to adequately care for actual failure if it occurs.

The electrocardiogram has become a must in cardiac evaluation — perhaps more by tradition than by value. This is not to say that it is of no value, but I feel that its usefulness is highly overrated in this particular situation. To be sure, a majority of acute coronary closures will be demonstrated by this method. For that reason it has a place. On the other hand, it is unnecessary in determining functional capacity. The presence of this or that pattern becomes a fine scientific point. It bears very little practical relation to the problem at hand. I grant that the presence of a normal electrocardiogram is a great assurance, but the mere presence of a chronic electrocardiographic abnormality is not sufficient to eliminate the patient from necessary surgery.

In the field of arrhythmias the electrocardiogram is very helpful, although, as a rule, such arrhythmias may be diagnosed clinically.

Determination of the blood pressure is a part of the examination. Actually an elevated blood pressure in itself is not a sufficient reason to defer surgery. On the other hand, as I have indicated, it does carry with it a statistical tendency to coronary disease.

The examination of the heart with the stethoscope will give information regarding rhythm, heart sounds and murmurs. Valvular heart disease not in failure causes no great problem in surgery except for aortic stenosis. This lesion, with its great left ventricular work-load and poor coronary filling due to a low aortic pressure, cannot be dismissed lightly. Although the work-load in anesthesia and surgery is not greatly increased, any drop in blood pressure or oxygen tension could prove disasterous. Most other valvular lesions when compensated should cause little difficulty.

The arrhythmias can be troublesome. The presence of an auricular fibrillation increases the surgical mortality considerably. There are statistical studies which show a mortality of 40 to 50 per cent following surgery on such individuals. I do not believe that this is true today with adequate digitalization and better postoperative care.

Ventricular premature beats, although not necessarily pathological, are an indication of increased hyper-irritability of the ventricle. For such patients the choice of anesthetic is limited. Certainly cyclopropane, which in itself produces this arrhythmia, is to be avoided. If the premature beats are frequent enough, treatment with quinidine or pronestyl may be indicated preoperatively.

Auscultation of the lungs for the rales of passive congestion must be carried out. The presence or absence of edema can easily be ascertained. Palpation of the right upper quadrant will determine the presence of liver enlargement. These few short tests will be adequate to determine whether or not significant cardiac failure is present.

The examination having been made it now becomes necessary to determine which patients may

undergo surgery. The following categories may be established:

1. All patients without symptoms or signs of functional inadequacy as evidenced by dyspnea, pain or edema may be operated under proper circumstances.
2. Patients with failure who have been previously compensated by medication are operable.
3. Patients with cardiac enlargement of over 55 per cent of the chest diameter may be operated after therapy.
4. Patients with auricular fibrillation or frequent ventricular premature beats will require therapy before surgery.
5. Patients with marked angina of effort or excitement or those with status angiosis will have an increased mortality and require extreme caution to avoid any lowering of oxygen tension or drop in blood pressure.
6. Acute myocardial infarction carries a high operative mortality and must only be subjected to surgery if the condition requiring the surgery has a higher mortality in itself—which is extremely rare.

The preoperative care of the cardiac is not difficult. Congestive failure requires adequate digitalization and diuresis to eleminate the failure. A definite decrease in salt and fluid intake will be required. The arrhythemia such as auricular fibrillation, auricular flutter and excessive premature beats should be treated and the patient adequately protected with drugs during anesthesia.

Above all, the preoperative care of the cardiac patient requires much psychological reassurance. These patients are more than ordinarily anxious about impending surgery. They have heard about the terrible things which happen to cardiac patients in surgery, and their natural anxiety only increases their problem. The work of the heart and incidence of arrhythmias are all increased by such anxieties. A very reassuring approach on the part of the surgeon and the cardiologist will do as much for the cardiac patient who is to undergo surgery as all medications combined. The display of anxiety concerning the patient's condition on the part of his physicians can be disastrous.

The choice of anesthesia is important. Certainly any anesthetic which decreases oxygen tension is to be avoided. This would immediately eliminate nitrous oxide. These forms of anesthesia, such as spinal, which have a tendency to drop blood pressure are to be avoided in patients with coronary or aortic heart disease. They should also be avoided in those whose blood pressures may have been high for years and in whom cerebral circulation has already adjusted to the high value and cannot adjust to a low value. As already indicated, cyclopropane is not to be used in individuals with arrhythmias such as premature beats.

Postoperatively, the surgeon must remember that his patient is a cardiac. In those with previous failure or minimal cardiac enlargement, excessive amounts of fluid and salts are to be avoided. I am certain that many a patient has met an untimely death by reason of over-hydration after surgery. The amount of fluid exchange required daily is not excessive. Cardiac patients get along adequately for years on a daily fluid intake of 1,200 to 1,400 cc. There is no reason why that same patient will require an intake of 2,500 to 4,000 cc. just because of surgery. I am certain that many more cardiac patients die by reason of over-hydration than ever die by reason of dehydration. If intravenous fluids are needed, the avoidance of sodium will do much to avoid accumulation of fluid in the tissue. Mercurial diuretics are not harmful and may be used daily in order to produce adequate urinary output.

Above all, a surgeon must remember that cardiac therapy required before surgery must be continued after surgery. The difficulties in the postoperative period are just as great as in the time prior to or during surgery.

The Pelvic Stress Syndrome

● *Here is a common ailment of women which has been quite successfully treated by the author using oral testosterone. Many a physician has tried a wide variety of approaches to this problem, and here is a treatment that can be expected to give a fairly high percentage of good results.*

JOSEPH W. GOLDSMITH, M.D., F.A.C.S.
Saint Paul, Minnesota

THE PELVIC stress syndrome is a clinical entity characterized by backache, lower abdominal pain and frequently associated with premenstrual tension (headache, irritability, breast engorgement and fluid retention), menorrhagia, metrorrhagia and fatigue.

Incidence

The exact incidence of this sydrome has not been determined but in the experience of the author, it was found in more than one third of all gynecologic patients seen in the office. It may be present at any age during the active menstrual life of the female but is more common in the pre-menopausal or early menopausal age group. Table I shows the incidence in a group of 200 unselected patients. In this study, no patient was older than fifty-six years of age.

Parity is related to incidence only on an age basis for, in general, parity tends to increase with age. The effect of parity on incidence in this same group of 200 women is shown in Table II.

TABLE I. FREQUENCY

Age Group	Number	Per Cent of Total
15-19	1	0.5
20-24	4	2.0
24-29	12	6.0
30-34	26	13.0
35-39	77	38.5
40-44	52	26.0
45-49	18	9.0
50-55	10	5.0
Totals	200	100.0

TABLE II. PARITY

Parity	Number	Per Cent of Total
0	19	9.5
1	31	16.5
2	46	23.5
3	56	28.0
4	28	14.0
5	12	6.0
6	4	2.0
7	3	1.5
8	1	0.5
Totals	200	100.0

No conclusions could be drawn as to the relationship of race to incidence since all but three of our patients were Caucasians.

Etiology

No single etiologic factor was found to explain the entire syndrome although many of the objective findings indicated that an increase of estrogens may have been an important causative factor. Taylor, in 1949,[1] interpreted similar findings and symptoms as being of vascular origin. However, it can definitely be shown that neither infection by any known agent nor a neoplastic process are

From the Departments of Obstetrics and Gynecology, St. Joseph's Hospital, Saint Paul, Minnesota, and the University of Minnesota Medical School, Minneapolis.

Read at the meeting of the Minnesota Society of Obstetrics and Gynecology, Rochester, Minnesota, May 3, 1958.

a part of this condition. At the present time, an experimental project is underway in an attempt to prove the estrogen hypothesis.

Symptomatology

The outstanding complaint of patients exhibiting this syndrome was backache (Table III). It was present in 194 (97 per cent) of the women in the study group. It may be the only symptom but frequently it is associated with others.[2] It may vary from a dull, intermittent, inconstant, low, nagging type of pain to a severe, sharp constant one. Typically, it was present in the lumbosacral, sacroiliac or sacral regions and often radiated to the posterior aspect of one or both thighs.

Almost as common was the complaint of abdominal pain in 190 women (95 per cent). Typically, this was lower abdominal in location, in one or both lower quadrants. It, too, may vary from a dull, inconstant ache to a severe, constant, knife-like pain. In a much smaller number, pain was generalized throughout the abdomen (8 or 4 per cent) while in seven other women, it was confined to the upper abdomen, especially the epigastrium. In only five patients inconstant nausea, vomiting, diarrhea or constipation were outstanding complaints and frequently such symptoms were not present on consecutive days. They had no constant relationship to food, menses or urinary function. The abdominal complaints seemed to be identical to those described in other tension states. Dyspareunia because of pelvic pain was also relatively common (54 per cent).[2]

Associated with backache and abdominal pain were the symptoms comprising premenstrual tension. In order of frequency these were premenstrual breast enlargement and tenderness (61.5 per cent), abdominal enlargement or "bloating" (59.5 per cent), nervousness and irritability (57.5 per cent), mental depression (32 per cent) and peripheral edema (21.5 per cent), especially in the lower extremities and an increased desire for salt or salty foods. Some patients noted in the week or ten days prior to menses, that they had to increase the size of their brassieres and, less commonly, a few complained that in this same period their shoes no longer fit. It should be noted that although some of the study group were concerned about sizable weight gains, all such women admitted to compulsion or "nervous" eating.

The fourth most frequently-noted group of of the features of adenocarcinoma such as scant,

TABLE III. SYMPTOMS

Symptom	Incidence	
	Number	Per Cent of Total
Backache	194	97.0
Abdominal pain	186	93.0
Both lower quadrants	101	50.5
Right lower quadrant only	48	24.0
Left lower quadrant only	12	6.0
Upper quadrants only (one or both)	10	5.0
Generalized	8	4.0
Epigastric region only	7	3.5
Premenstrual tension	126	63.0
Breast engorgement	123	61.5
"Bloating" or "gas"	119	59.5
Nervousness and/or irritability	115	57.5
Depression	64	32.0
Peripheral edema	43	21.5
Menstrual irregularities	107	53.5
Shorter cycles	89	44.5
Premenstrual spotting	84	42.0
Menorrhagia	43	21.5
Postmenstrual spotting	41	20.5
Total irregularity	16	8.0
Infertility	99	49.5
Fatigue	95	47.5

symptoms was menstrual irregularity. More than half (53.5 per cent.) of our group noted menstrual changes. Progressively shorter cycles was the usual complaint although many of these patients also observed premenstrual spotting of from one to seven days' duration, usually described as a dark brown or "dirty" discharge. Forty-three (21.5 per cent) of the group experienced prolonged or profuse menstrual flow with one or more periods (not always consecutive). Curettage was done on the majority of these women as will be noted below. Forty-one (20.5 per cent) complained of postmenstrual spotting of from one to five days' duration and in sixteen women (8 per cent) total irregularity of both cycle and flow was present.

Almost half of the group (ninety-nine) manifested infertility.[3] However, this complaint was most difficult to evaluate since many women in our group, especially those in the premenopausal age group, were actively trying to avoid pregnancy. Of the others, infertility represented one of the main reasons for seeking medical aid, originally. The duration varied from one to nine years and of the patients who were concerned about their inability to achieve pregnancy, almost two-thirds (sixty) had at least one child.

Unusual fatigue was present in ninety-five (47.5 per cent) of the patients. A much larger number mentioned fatigue together with the general symptoms of stress but in the group under discussion, fatigue was present out of proportion to effort or exertion.

Findings

Pelvic examination revealed tenderness particularly in the adnexal regions and in the sacro-uterine area. This was found in all patients in this series but the degree varied considerably and could usually be related to the length of time that symptoms had been present. Less than 10 per cent had sacro-uterine tenderness without other pelvic sensitivity, but in 84 per cent, thickening of the sacro-uterine ligaments was found. One hundred and seventy-three (86.5 per cent) of the group had third degree retroversion of the uterus which was found to be relatively immobile in practically all cases. Attempts at reposition without anesthesia were usually unsuccessful only because of the severe pain this maneuver produced. No other consistent pelvic findings were present although an average number of small, silent myomata, vaginal infections and cervical erosions were discovered.

Abdominal tenderness was found in 190 (95 per cent) of the 200 women, without accompanying muscle spasm or rebound tenderness. The location of the tenderness corresponded to the site of symptomatic discomfort although in thirty-two women, it was more generalized than the pain would indicate.

Laboratory studies were of significance only from a negative standpoint. White blood cell, differential and red blood cell counts as well as sedimentation rates were all within normal limits. Papanicoloau smears were class 1 and 2 smears. Cultures for gonococcus were taken in about half of the patients (ninety-nine) and were negative. Seventy-six women were subjected to curettage because of abnormal bleeding or spotting. The pathological diagnosis in all instances was proliferative endometrium even though surgery was performed in the presumed premenstrual phase, where possible, or during the prolonged bleeding stage. In ten instances, there was stromal hyperplasia without accompanying glandular enlargement.

In forty-six patients, an opportunity to examine the peritoneal cavity (especially the pelvis) on the operating table occurred during the period of this study. Surgery was performed in fourteen cases for conditions other than gynecologic ones (cholecystitis with cholelithiasis, possible ruptured peptic ulcer and acute appendicitis) while the remaining thirty-two women were explored because of severe pain which did not respond to therapy or under the erroneous diagnosis of ruptured ectopic pregnancy or endometriosis. In all of the forty-six, the pelvis was free of infection, endometrial implants or other significant pathologic findings. Third degree retroversion was present in thirty-five instances (75 per cent) but none of these uteri were fixed and they could be easily elevated into an anterior position.

TABLE IV. RESULTS

Classification of Results	Study Group		Control Group	
	Number	Per Cent	Number	Per Cent
Markedly Improved (Asymptomatic)	167	83.5	0	0
Moderately Improved	23	11.5	31	15.5
Unimproved	10	5.0	169	84.5

Treatment

Since it has been established that testosterone is an antagonist to estrogen, male hormone was administered to members of the study group. Empirically, it was decided to limit the dose to a maximum of 300-350 mg. per month to minimize possible side effects since this has been shown to be the critical level above which such side effects appear. A sublingual tablet was selected and an initial dose of 6 mg. twice daily was established after other amounts had been tried. As improvement became evident (both subjectively and objectively), the daily dose was gradually reduced until a maintenance level was reached. In the majority of our patients, this was found to be between 1.5 and 3 mg. daily.

As a control to the study group, a tablet of the same size, shape and color (composed entirely of lactose), was given to another group of 200 women. With this exception, the control group was identical to the study series.

Results

The results in the study and control groups are shown in Table IV. These findings were tabulated after ninety days of therapy. It should be noted that there is a latent period of at least fourteen days before improvement is noted by either the patient or the physician. Thereafter, amelioration of symptoms and pelvic findings is usually slow but progressive, reaching a maximum in from forty-five to seventy days, depending largely on the length of time the condition had existed prior to initiation of therapy.

It is readily apparent from Table IV that after

three months of testosterone therapy, 95 per cent of the study group were either markedly improved (asymptomatic) or moderately improved as contrasted to only 15 per cent of the control group who claimed moderate symptomatic improvement although, clinically, no change was found upon pelvic examination.

It is interesting to note that this improvement could be maintained indefinitely on a maintenance dose of testosterone, whereas, if the medication were discontinued after a period varying from eight months to two years, both the symptoms and objective findings returned. However, this recurrence was again reversible with resumption of the medication. Twenty-eight patients (14 per cent) became pregnant after from three to ten months of therapy. These women had all originally sought medical care because of infertility rather than pain.

Minor side effects occurred in ten patients (5 per cent). Five complained of increased hirsutism while four developed acne and one woman noted both of these complications. Medication had to be discontinued in six other patients because it produced nausea. The acne disappeared rapidly after testosterone was stopped but the hirsutism has persisted. No other untoward effects were noted.

Differential Diagnosis

Four other conditions producing some or all of the symptoms and/or findings found in the pelvic stress syndrome are to be differentiated from it.

The lack of localized tenderness, abdominal muscle spasm and rebound tenderness will most often allow *appendicitis* to be excluded. Further aid may be obtained from the blood counts, sedimentation rate and pelvic findings.

Elevated sedimentation rates, leukocyte count and a change in the differential count as well as other evidences of infection (increased temperature and pulse rate) will be present in *acute salpingitis* but not in the stress syndrome. Positive cultures for gonococci or other pyogenic organisms may further aid in differentiation.

In *ectopic pregnancy*, a history of amenorrhea with the subsequent appearance of abdominal or pelvic pain and bleeding are present but absent in pelvic stress. Symptoms of shock (due to intra-abdominal hemorrhage) are never present in the stress syndrome.

Strictly speaking, *endometriosis* is a pathologic diagnosis and differential diagnosis is easy since there are no pathologic findings in the stress syndrome. At surgery, endometrial implants are specific for endometriosis. Clinically, however, these two conditions may be indistinguishable.

Discussion

The name pelvic stress syndrome was selected by the author because of the association of the pelvic symptoms and findings with those of other stress conditions (abdominal, premenstrual, et cetera). It is similar, if not identical, to Taylor's vascular syndrome.

No claim is here made that testosterone will do more than arrest the condition. The only "cures" noted have been in those women in whom ovarian function has been destroyed, naturally or artificially. Nor is any claim made that testosterone will eliminate the associated infertility although, as has been noted, twenty-eight women in the study group did become pregnant after three or more months of therapy. The importance of this study lies in the elimination of pelvic distress and backache while maintaining ovarian and menstrual function.

Summary

A clinical syndrome called pelvic stress syndrome characterized by backache, lower abdominal pain, tension states, menstrual irregularities and fatigue has been described.

Incidence, symptoms, findings, treatment and differential diagnosis have been given.

The results of treatment in a controlled series consisting of 200 women are given.

Acknowledgment

The author wishes to thank Mr. M. Cain and the Ayerst Laboratories for their contribution of the Testosterone Lingusorbs® used for some of the patients in this study.

Intracapsular Fracture of the Hip

The Use of Substitution Femoral Head Prosthesis in the Primary Treatment

Treatment of fresh fractures of the femoral neck by excision of the femoral head and introduction of a prosthesis is advantageous in elderly patients. Fifteen patients so treated are discussed briefly.

LESTER W. CARLANDER, M.D.
Minneapolis, Minnesota

Presented as an Inaugural Thesis before the Minneapolis Academy of Medicine on October 21, 1957.

THE PROBLEMS presented by an elderly person with a fracture of the hip are familiar to all. Fractures of the hip are generally divided into two broad classifications: the intracapsular fractures, in which the fracturing is in the neck of the femur within the capsule of the hip joint itself; and the fractures of the trochanteric area, variously termed intertrochanteric, pertrochanteric and subtrochanteric.

The trochanteric fractures, in general, may pose a more difficult problem in stabilization or immobilization. With adequate treatment, however, they usually will heal and we do not usually see necrosis of the femoral head develop when the fracturing is in this location.

With intracapsular fractures of the femoral neck, we are usually faced with a fracture which needs to be reduced and secured in this position of reduction by means of internal fixation in order to obtain healing of the fracture. However, even though the fracture heals, a considerable number of these hips will develop avascular necrosis of the femoral head because of impaired blood supply to the femoral head due to the site of the fracture.

A case typical of this problem might follow a course such as this: An eighty-year-old lady fell and suffered an intracapsular fracture to her hip. The day following, this was reduced and internally fixed. A period of convalescence followed during which time the patient could be up in a chair but she was not allowed weight-bearing in any form. Healing was followed by x-rays and after a period of perhaps three to six months postoperatively, healing appeared satisfactory and the patient was allowed to bear weight on this leg. This might be followed by a period of a few months to a year or more without discomfort and then the patient begins to develop aching pain in the groin, hip, or thigh with walking and x-ray shows avascular changes in the femoral head with flattening or crumbling of a portion of the weight-bearing surface. We are once again faced with a patient who is at least partially a hip invalid and who requires treatment which may vary from limitation of activity, partial protection

of hip by use of cane, osteotomy of femur to change the weight-bearing thrust in the hip, arthroplasty of the hip, or insertion of a substitution femoral head prosthesis.

In any consideration of this problem it is, of course, important to know about how often this complication occurs. In various reviews of series of intracapsular fractures of the hips treated by various means of fixation, it would appear that there are between 10 and 15 per cent of the intracapsular fractures of the hip which fail to unite for one reason or another and of the remaining fractures which do heal, various series show 25, 33, and 40 per cent incidence of avascular necrosis of the femoral head developing later.

During about the last fifteen years, various femoral head prostheses have been developed for treatment of major difficulties in the hip arising from severe changes in the femoral head. Much credit should go to the Judet brothers in Paris for their early work in development of an endoprosthesis for the femoral head. They used a stem type of prosthesis which was much like a mushroom in shape and the stem simply inserted down the neck of the femur after removal of the head. Through the subsequent years, many various types of prostheses have been developed and used. Some of these have been developed of various plastics and others of stainless steel alloys or Vitallium. Some of them have been stem type in that the stem passes down only through the neck of the femur, others have been intramedullary in type in that the prosthesis inserts through the neck and down the medullary canal of the shaft of the femur. In general, the plastic prostheses have not worn well and there is a definite incidence of reaction to them. The consensus of opinion also rather generally favors the use of the intramedullary type of prosthesis which affords a more complete anchoring and therefore greater stability of the endoprosthesis.

Because it so often seemed unsatisafctory that an elderly person with a fractured hip would spend so many of his remaining days a hip invalid, numerous orthopedists have tried to see if the use of a femoral head prosthesis as the original treatment of the intracapsular fracture of the hip would be a satisfactory alternative.

We have had occasion to follow this form of treatment in a number of patients during the last two years. We have confined this type of therapy to the more elderly group because we still feel that for the patients with a considerable life expectancy ahead, it is worthwhile to try for a healed fracture and hope that aseptic necrosis will not develop.

This paper is devoted to a brief evaluation of fifteen such patients treated in the period of one year, all at least six months ago. This number of cases is far too small for this paper to be a statistical review. Evaluation of the results are in terms of what it has meant to the patient in terms of activity, not detailed studies of range of motion. The outcome in any individual case must be considered successful or unsuccessful as compared to what could be anticipated. For example, in a patient who is partially disoriented, requiring rest home care, and who, prior to his fractured hip, has only walked from the bed to the wheelchair and to the bathroom, a good result would be to once again return him to this degree of ambulation where he can walk a bit and be relatively independent and does not have to be lifted and cared for as a bed patient.

Evaluation of Patients

Age.—A quick survey of these fifteen consecutive patients reveals that their average age was seventy-nine years.

Length of Hospitalization.—The average hospital stay postoperatively was fifteen days. All patients at the time of dismissal from the hospital were ambulant to some degree with assistance.

The Operation.—The operative procedure as performed on these patients consisted of a lateral approach to the hip with the patient lying upon the opposite side, a release of approximately the anterior one-third to one-half of the gluteal medius and minimus attachment to the trochanter, an anterior arthrotomy of the hip, and then dislocating the hip anteriorly. The head is removed from the acetabulum and the ligamentum teres or any other soft tissue at the base of the acetabulum is removed. The neck is then prepared for the insertion of the prosthesis, and the prosthesis of proper size inserted, checked to see that it fits well, and then reduced into the acetabulum. It has been my practice always to test the hip while the capsule is open to be sure that external rotation will not easily dislocate the hip again. The capsule is then closed, the muscles

reattached to the trochanter and the wounds closed.

Type of Prosthesis.—In all of these fifteen patients an Austin-Moore type of intramedullary prosthesis was used. This is a metal prosthesis, cast from Vitallium, with fenestration in the shaft portion through which subsequent bony growth may give further stabilization. At all operations we have the Minneapolis prosthesis available because, in its present form, we feel it is an equally excellent prosthesis and actually is preferable if for any reason the Austin-Moore prosthesis seems loose in the shaft after insertion.

Operative Risk.—As can be seen from the average age of seventy-nine years, this procedure has been carried out on the very elderly. It is a larger surgical procedure than reduction and pinning of a hip in which it is not necessary to open the capsule. However, it does not take any longer in operative time and can often be done more quickly. The average operative time for these patients from a start of operation to completion, including skin closure, was about seventy minutes. About 40 per cent of these fifteen patients received one pint of blood with their surgical procedure. It has been our belief that, unless the patient is actually moribund or in such poor general condition making highly improbable his survival during the immediate convalescence, he will tolerate this procedure. The anesthesia which has typically been used in this group has consisted of spinal block, using between 6 and 10 mg. of pontocaine. Sufficient reinforcement has been used simply to dose any patients who are apprehensive.

Mortality.—Two of the patients are deceased, both of them succumbing during their postoperative convalescence. One of these patients was an eighty-five-year-old lady who appeared to tolerate the procedure very well and had a good convalescence until the tenth day when she died of a coronary occlusion. The second was an eighty-five-year-old man who had fallen in the rest home where he was being cared for because of age and disorientation. Subsequently, in his convalescence the patient developed first an abrasion and subsequently an open sore on his elbow from rubbing on the sheets which then flared into a severe cellulitis of the arm. We were unable to control the inflammation with chemotherapy and the patient expired the seventeenth postoperative day. The hip wound, incidentally, healed well and was not involved in this process.

Complications.—Aside from the above deaths, one patient's convalescence was complicated by development of a low grade phlebitis of both lower extremities. There have been no infections in this group although, subsequently, one patient developed a septic wound. There have been no dislocations of the prothesis.

Postoperative Care.—Postoperatively, these patients have not been immobilized in any apparatus. Early motions have been encouraged commensurate with the patients' condition. They are allowed up in a chair within the first few days and allowed walking with support by the end of the week. It is found easier to ambulate some of the very disoriented patients with two people helping them from either side; others may use the walker, and others learn to use crutches. Assisted walking with a prosthesis is, of course, much easier since the patient is allowed partial weight-bearing on this leg, whereas, with a fracture which is pinned, we need to avoid all weight-bearing and this is very difficult for many elderly people.

Present Status of Patients.—As has been suggested previously, the end result in some of these situations may seem inadequate unless we continue to bear in mind that one purpose of the procedure may justifiably be simply to lessen the care required by the patient.

One patient, an eighty-year-old man, continues to receive rest-home-care and does not walk upon his leg. He is helped up daily and divides his time between the bed and the wheelchair. This patient is disoriented and uncooperative due to cerebral arteriosclerosis. He has developed a flexion contracture of the hip from constant sitting and lying in bed with the hip flexed. Physical therapy was advised early, but the family deemed that the patient was so uncooperative and out of touch with reality that sufficient benefit would not be forthcoming.

Two other patients continue to have rest-home-care because of moderate degrees of disorientation due to cerebral arteriosclerosis. The one patient, a seventy-five-year-old lady, is doing very well and apparently has no pain. She is up daily. She is not allowed to walk by herself because it is felt she cannot be trusted. She does walk from bed to wheelchair, to the bathroom, and about the rest home simply with someone at her arm. The other patient, an eighty-five-year-old man,

continues at the rest home where he resided at the time of his fall. He is independent in his care. He uses two canes much of the time when he walks. He is able to get in and out of the bathtub himself, is able to negotiate stairs himself, and complains of no pain.

Two of the patients complain of definite discomfort in the hip with walking. Both patients are at their homes and are partially ambulant during the day. The one patient, a seventy-eight-year-old lady, walks about the house usually holding onto furniture, is independent in her care as far as dressing in the bathroom and getting around her home. She complains of discomfort in this hip after being up and is also partially handicapped by pain of arthritic nature in the opposite hip and both knees. The other patient is an eighty-five-year-old lady who is markedly kyphotic in build and needs to be propped up constantly in bed to rest and breathe comfortably. She is the patient who developed swelling in both legs with low grade phlebitis. It has been my feeling that her position requiring constant flexion of the hips may have been a factor in this. She is at home, walks to the bathroom, around the house by herself using a cane or holding onto the furniture and gets in and out of bed without being lifted. She has discomfort in her hip for which she uses aspirin. She also has discomfort in her back which is independent of her hip trouble.

The remaining cases are as follows:

One patient is an eighty-year-old lady who is somewhat disoriented and disturbed. The day following her operation she was out of bed walking and sufficiently active so that she threw a pitcher of water through the hospital window. She went home in ten days because it was felt that she might be less disoriented there. At the present time she walks around her home usually using a cane. She helps with the housework to a mild degree. She dresses and cares for herself. She has no pain but she states that she tires easily, describing this as a general tiredness.

A seventy-nine-year-old woman is at her own home and continues to care for it. She can walk without support but prefers to use a cane because she feels more sure of herself. She goes up and down stairs, cares for herself and her home, describes slight swelling in the foot if she has been on it a great deal during the day. She states that she has no discomfort.

A seventy-seven-year-old man, who now has gone back to live by himself, cares for himself and his home. He gets up and down stairs. He uses a cane when he walks. He has some discomfort in the leg for which he uses Absorbine Jr.

An eighty-three-year-old woman who is living at her children's home, states that she has some aching at night until she gets settled comfortably. She tends to use one crutch a good deal of the time around the house. She cares for herself, gets up and down stairs without assistance, and helps keep house for her children, both of whom work.

A seventy-two-year-old woman, had a radiation fracture following x-ray treatment for an adenocarcinoma of the uterus. The fracture was not immediately recognized until it displaced, at which time we saw the patient and elected to treat her with a primary prosthesis. This patient is ambulant, walks most of the time without cane or crutches, and has, I believe, been to California and back visiting. She describes some aching in the hip after working in her garden, but in general has done very well.

A seventy-one-year-old lady, who had a very high subcapital type of fracture, at the present time walks well without support and without appreciable limp. She is active, cares for her home and describes some aching in her hips and knees which is bothersome but not handicapping.

A seventy-nine-year-old woman, who, at last report was doing very well—was active, walking with or without cane, was having no pain or discomfort and was caring for her home and herself.

Finally, a seventy-one-year-old woman who did very well postoperatively, at last report wrote that she was having no pain, was walking daily and was independent in her care.

Indications for the Use of Primary Prosthesis In Intracapsular Fractures

At the present time, it is my feeling that the possible indications for the use of reconstruction of the hip by insertion of a femoral head prosthesis in the primary treatment of an intracapsular fracture are as follows:

1. Very advanced age of the patient where it makes possible early ambulation and some degree of independence during their remaining life.

2. When the patient is somewhat disoriented or incapable of full co-operation. As we all know, such patients cannot be prevented from getting out of bed unless they are restrained or constantly supervised. Such immediate weight-bearing has to be avoided after the fixation of a fracture, but does not appear to be any great calamity after the insertion of a prosthesis.

3. The patient, who, because of age, general feebleness, impaired vision, or impaired use of extremities such as after cerebral vascular accidents, is going to be unable to use crutches effectively without weight-bearing during the period of four to six months after surgery. Many of these patients will be able to walk with support where they can bear some weight on both legs, and in this way use of primary prosthesis may greatly lessen the amount of care that they require in their home or rest home.

4. We feel somewhat more inclined to use a femoral head prosthesis in fractures which are of the extreme sub-capital type although this paper

has not attempted to evaluate the indications for use on basis of the site of fracturing in the neck in the intracapsular fractures.

Conclusions

In conclusion, I would feel that the following statements with regard to the use of a primary prosthesis are probably justifiable: (1) That a primary prosthesis does not give as normal or painless a hip as a well healed fracture which does not develop avascular changes in the head. (2) That a prosthesis does allow early ambulation of the patient facilitating the care of the very elderly patient. (3) That the use of the primary prosthesis does avoid the complication of avascular necrosis in the healed fracture. (4) That the prosthesis will allow most patients to be independent in care of themselves, to be ambulant to the degree required of their years, and may avoid major "hip invalidism" during their waning years.

Discussion

RICHARD E. REILEY, M.D.: This paper is an excellent paper and demonstrates the type of conservative thinking which is fairly prevalent in this area. It demonstrates very clearly the careful selection of cases. The tendency in many areas is to become enthusiastic about a gimmick which has not been given thorough evaluation. It has been proven in the past and we are all well aware that there is no substitute for an intact femoral head which has remained viable following a fracture of the neck.

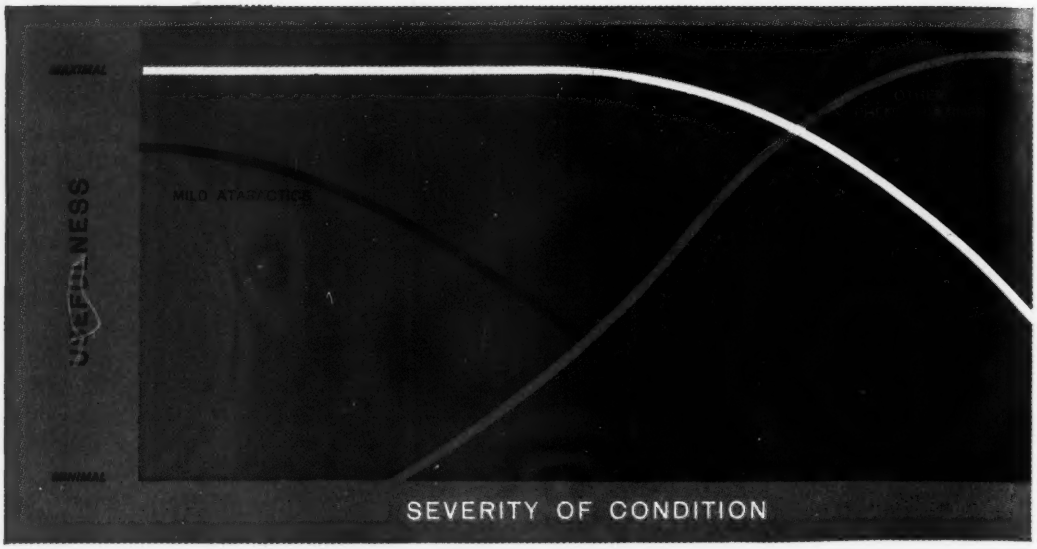
The main consideration in these instances is that of an elderly patient with a hip fracture. In many instances this represents an economic catastrophe. It involves periods of long hospitalization and care and, in many instances, what small resources these people have are used up and their care depends upon a city, county or state agency or relatives who are in no position to care for the patient, either personally or financially. Thus far, no definite age limitation has been set. It was originally set at seventy years as an arbitrary figure but there has been a great variation in the age of the patients involved in whom hip prostheses have been used. Most hip prostheses have an advantage in several ways in that they do not require x-rays during the surgical procedure and consequently surgical time can often be reduced rather substantially when a prosthesis is used. As far as surgical approaches are concerned, this seems to be an individual matter. We have found that the posterior approach is easier for us although many are using the posterolateral approach or a lateral approach and the anterior approach. Indications for the use of a hip prosthesis have to be considered individually. However, we consider the patient who is a hemiplegic with a fracture of the neck of the femur on the hemiplegic side to be an absolute primary indication for the use of a femoral head prosthesis.

During the development of prostheses it has been shown in the past that the plastic materials which have been used, such as nylon, have proved to be entirely unsatisfactory. Materials now most commonly used are Vitallium and stainless steel. We see no particular advantage of one material over the other and feel that this is simply a matter of choice on the part of the surgeon. During the development of the Minneapolis prosthesis, originally the femoral heads were removable and were obtainable in various sizes. The stem-portion of the prosthesis was made in two sizes and the heads were also made in different diameters, and simply the diameter which fitted the acetabulum properly was selected and screwed onto the stem-portion of the prosthesis. However, this procedure was discontinued after one patient had the stainless steel head unscrew within the hip joint. Many of these patients have had spectacular results such as one sixty-seven-year-old woman, a diabetic, who sustained a fracture of the neck of the femur followed by a nonunion of the neck fracture after which a prosthesis was inserted. One year later she fractured the neck of the opposite femur and since it was a fracture low in the neck, it was fixed by internal fixation. The fracture promptly fell apart and the prosthesis was inserted some three months after the original fixation of the fracture. This patient now attends dances regularly, bowls, and does all of her own housework and gardening.

In one other instance, white man aged twenty-six, with rheumatoid arthritis and ankylosis of both hip joints, had bilateral prostheses inserted and is now self-sufficient and is working.

In conclusion, I think this is an excellent paper that demonstrates a conservative and individualized approach to the treatment of the elderly patient with a fracture of the femoral neck.

JOHN H. MOE, M.D.: I appreciated hearing Dr. Carlander's paper, and do not have anything specific to add to what he has said. A ten-year or fifteen-year follow-up may show that the acetabulum will wear away from a metal prosthesis. It would appear to me that in the presence of long-standing conditions where the hip has not been used adequately and a considerable amount of bone atrophy is present, or in the event that a reaming out of the acetabulum is necessary in the insertion of the prosthesis, that the tendency toward complications of pain and wearing away of the acetabulum are much greater than they are in the fresh fracture. The use of the prosthesis in the fresh fracture appears to give excellent results for the most part. I think that Dr. Reiley is to be congratulated on his excellent work in the development of a good prosthesis, and I would also wish to congratulate Dr. Carlander on an excellent presentation of a timely subject.



D. KEITH MILLETT, M.D.: I believe that Dr. Carlander is to be congratulated on delivering a very excellent paper on a very timely subject. There is no doubt that the replacement femoral head prosthesis has a very definite place in the treatment of sub-capital fractures of the femur, especially in elderly patients. The operation can be carried out easily and quickly with very little increase of operative risk over that involved in pinning the fracture hip. The convalescence is generally much more rapid, favoring earlier ambulation and usually greatly decreasing the convalescent nursing care required. I believe the operation, as presented by Dr. Carlander, should be in the armamentarium of every surgeon treating hip fractures. I want to thank Dr. Carlander again—it was a very excellent paper.

LESTER W. CARLANDER, M.D.: (closing discussion): I wish to thank the discussants of the paper for their fine comments and to re-emphasize, as brought forth in the body of the paper, that we feel that where there is a possibility of many years of use of the hip in the future, that the advantage of an uncomplicated healed fracture is sufficient, so that the standard treatment by internal fixation of these fractures in this situation is still preferable.

ANNOUNCING

A HIGHLY EFFECTIVE TRANQUILIZER FOR EXTENDED OFFICE PRACTICE USE

POSITIVE CALMING ACTION ADAPTED FOR LOWER RANGE OF EMOTIONAL DISORDERS

The development of TENTONE® Methoxypromazine Maleate *Lederle* does not duplicate primary function of existing tranquilizers. TENTONE fills the need for a practical, potent agent for extended use in everyday practice (as illustrated above).

Action of TENTONE Methoxypromazine Maleate approaches that of the strong phenothiazines without their drawbacks. Calming response is positive and rapidly apparent to both patient and physician. However, as a basic phenothiazine modification, TENTONE allows full therapeutic application in the mild and moderate range of anxiety-tension and somapsychic disorders most usually seen in general practice.

EXCELLENT TOLERATION— MARKED REDUCTION IN COMPLICATIONS

Incidence of untoward reactions is exceptionally low and approximates the mild ataractic drugs. Reduction in sensitivity reaction, intestinal distress, blood, brain or liver toxicity is striking, particularly in the low dosage range. TENTONE exhibits greater freedom from depression and drug habituation. Physical and psychic orientation is usually preserved. Occasional drowsiness may be encountered, particularly in higher dosages. In moderate to more severe cases, this sedative effect may be desired.

TENTONE has thus been described as one of the easiest tranquilizers to handle in office practice. In indicated cases, the physician may be relieved of the patient's unnecessary concern over his own illness. In contrast to the previous types of drugs, complaints over induced distress or inadequate benefit are rare.

WHEN MORE THAN MILD SEDATIVE EFFECT IS DESIRED

Consequently, TENTONE is more useful than other ataractic drugs in two areas: (1) mild to moderate conditions—when more than mild sedative effect is sought, (2) middle range of moderate to severe cases—when less than psychopathology is involved.

Indications include ■ common anxiety-tension states ■ obsessive-compulsive behavior ■ neurosis ■ depression ■ situational anxiety and hysteria

And the emotional components of: ■ agitation ■ restlessness ■ tremors ■ insomnia ■ alcohol- and drug-withdrawal syndrome ■ hyperkinesis ■ prenatal anxiety ■ rheumatic disorders ■ dermatoses ■ menopausal syndrome ■ premenstrual tension ■ peptic ulcer, other g.i. disorders ■ asthma, other allergy ■ multiple sclerosis, arteriosclerosis ■ malignancy, other progressive diseases

POSSIBLE POTENTIATION OF ANALGESICS AND NARCOTICS

Since tranquilizing drugs may potentiate the action of pain-relievers, sedatives, and barbiturates, they should be used with caution in conjunction with them, or to achieve a greater response to these drugs in various conditions when desired. They may also be useful in reduction of effective dosage to better tolerated, or non-habituating levels.

ADAPTABLE LOWER DOSAGE RANGES

Dosage must be individualized to severity of condition and response desired.

In mild to moderate cases: varies from 30 to 100 mg. daily.

In moderate to severe cases: from 75 to 500 mg. daily.

In psychotic or institutionalized patients, TENTONE may be useful as a substitute when toxicity precludes effective dosage of other phenothiazines, or as maintenance after hospitalization. Dosage may range from 100 to 1500 mg. daily in divided doses.

Supplied: 10 mg., 25 mg. and 50 mg. tablets

Meno-metrorrhagia, when due to atypia of the endometrium, presents an extremely delicate problem of diagnosis. Is the atypical endometrium benign, premalignant or frankly malignant?

Atypical Endometrial Hyperplasia in the Young Woman

RICHARD R. FLIEHR, M.D.

Minneapolis, Minnesota

Inaugural thesis presented before the Minneapolis Academy of Medicine, April 21, 1958.

IT IS NOT DIFFICULT to distinguish pathologically between definite adenocarcinoma and cystic hyperplasia of the endometrium. There exists however, a "middle-ground" between the two that has become, in recent years, a matter of great concern to pathologist and clinician alike. This is the so-called atypical endometrial hyperplasia or "carcinoma *in situ* of the endometrium" as termed by Hertig. It presents many of the features of a typical hyperplasia—the profusion of glands, the moderate cystic formation of these glands, and the tendency to polypoid overgrowth. It also has many of the features of adenocarcinoma such as scant, dense stroma, intraluminary glandular projections, anaplasia, numerous mitoses, stratification of the glandular epithelial cells and the like.

In young women, where conservation of childbearing organs is paramount, this represents a grave and perplexing problem. Such cases in young women are uncommon, but they are present; and when encountered they must be treated with a concerted, yet conservatively adequate, plan of attack.

It is the aim of this paper, then, to review what little is known of the subject, add another case report to the literature, and attempt to justify some rationale of treatment that will prove adequate and safe.

Report of Case

This case is that of a white woman, aged twenty-eight, married, who was first seen in our office on November 5, 1956. Her menarche had been at age thirteen, and apparently she had been a normal menstruating woman until the summer of 1950 when she began to have a rather continuous light uterine bleeding. She consulted no one about this for approximately a year until she

suddenly had a profuse hemorrhage which required curettage and several transfusions. This was done in Denver and the report of the curetted tissue was "endohyperplasia of the endometrium." Following this episode she had complete irregularity of her menses, going for periods of from three to four months without any bleeding, and then spotting for several days as well as experiencing profuse bleeding at intermittent periods. This continued until 1953 when she again had a dilatation and curettage in Honolulu. The report of this tissue was "adenomatous hyperplasia."

The patient's gynecologist in the Islands placed her on cyclic hormone therapy which seemed to help regulate her menses at first, but within a few months her periods again became completely irregular despite continued therapy. She was seen next in Palo Alto by a qualified gynecologist and again was curetted. I obtained these slides and the findings were an endometrium characterized by a dense stroma, scarcity of glands, and marked squamous metaplasia. Also of note were the anaplasia of cells and numerous mitotic figures. Her gynecologist termed this "icthyosis of the endometrium," which is rather an esoteric term but was evidently used as a description of the marked squamous metaplasia around the glands. As a matter of fact, one pathologist in reviewing these slides admitted that he would be sorely tempted to call this an adenoacanthoma, a frankly malignant lesion. Her Palo Alto physician took her off all hormone therapy and she had scanty monthly menses for seven months, when she again began having the same meno-metrorrhagia. A repeat curettage was performed at this time and the tissue showed a picture very similar to the previous curettings but with slightly more pronounced abnormal features.

This was in October of 1955, and she had no therapy but continued symptoms until seen in our office on November 5, 1956. I performed an office endometrial biopsy and got a rather typical picture of mid-menstrual endometrium with minimal adenomatous hyperplasia. Looking carefully, however, one could notice slightly more intraluminary budding of the glands than is usually seen in typically normal endometrium. The patient continued to bleed following the biopsy, however, so on January 7, 1957, she was hospitalized and a thorough curettage done. These were the findings that offered the great quandary (Fig. 1). Notice the budding into the glands. Now we notice the glands crowding out the stroma. In Figure 2, under higher magnification, one can see the stratification of the cells in the glands, and the numerous pale stained cells with pale nuclei.

Our pathologist reported this tissue as adenocarcinoma, but being somewhat dubious, he took them around to several other pathologists in the Twin Cities. The score came out about 50 per cent for adenocarcinoma and 50 per cent for an atypical form of hyperplasia. The slides were then sent to Dr. Malcolm B. Dockerty and Dr. Lawrence M. Randall at the Mayo Clinic, and to Dr. Emil Novak at Johns Hopkins. Dockerty and Randall were of the opinion that this was adenocarcinoma Grade I in an adenoma. Novak, on the other hand, could find no evidence of definite malignancy, yet frankly admitted that he could not say this tissue would not eventually become malignant. The results of all of these communications were presented to the patient, and on February 11, a total hysterectomy was done. The opened gross specimen showed nothing to cause great alarm other than a polypoid growth at the top of the cavity. Microscopic sections taken from the removed specimen showed essentially the same general picture as those of the curettage.

Discussion

It becomes obvious that this represents a lesion upon which pathologists and gynecologists cannot agree as to its malignancy. During the past decade —and even before—the subject has occupied some of the best minds in the country. Such men as Novak,[1,2] Hertig,[3,4] Speert,[5,6] Faulkner,[7] Aufwedson and Winblad,[8] and others have contributed to the literature on the subject.

What is there about this lesion that makes it atypical and the subject of concern to both the pathologist and the gynecologist? On this, all minds are agreed. Various combinations of the histological changes listed in Table I are always present.

TABLE I. HISTOLOGICAL CHANGES IN ATYPICAL ENDOMETRIAL HYPERPLASIA

Epithelial budding
Crowding of the glands
Lessened stroma
Tufts of epithelium protruding in the gland lumina
Outpouching of the glands
Stratification of the epithelial cells
Pale staining of the cells, especially the nuclei

Mitoses, even in fairly large number, are of very little help. The endometrium is a constantly changing and regenerating tissue. Mitoses are therefore very common, even in normal endometrium. Disparity in glandular size is also of very little significance. This also occurs in normal tissue, and very definitely is present in benign hyperplasia.

The entire subject resolves itself to the simple question of whether this atypical endometrial hyperplasia represents a pre-malignant lesion or not. Most gynecologists will agree that *any* form of hyperplasia, adenomatous or otherwise, in a *postmenopausal* woman who has not been receiving hormonal therapy is extremely dangerous. Total hysterectomy with bilateral salpingo-oöphorectomy is almost imperative in such cases. But what of a similar situation in a *young* woman? Especially if the woman is in the childbearing age and desirous of becoming pregnant?

Very little is known about the significance of

this lesion in the young woman, mainly because of the paucity of cases to study. Certainly we do know that adenocarcinoma of the uterus in the young woman is not as uncommon as originally reported. A study at the Roosevelt Hospital in New York[6] showed that 5 per cent of all cases of endometrial carcinoma were in patients under forty years of age. Since this age group represents a significant proportion of cases of malignancy, then the importance of attempting to recognize any pre-malignant lesion is doubly important.

Statistically, it is almost impossible to draw any conclusions from such a small number of cases reported in this category. Speert[5] reported sixteen cases of eventually recognized adenocarcinoma in which he reviewed previous curettings and found atypical changes in the endometrium. Three of these were in young women.

Hertig[3,4] reported in 1949 on sixteen cases of adenocarcinoma in young women. Five of these sixteen had one or more previous curettages which showed progressive change from simple hyperplasia through atypical adenomatous hyperplasia to frank malignancy.

TeLinde[9] has reported several cases which showed adenomatous atypical hyperplasia on curettage, yet when the uterus was removed, areas of frank malignancy were discovered coexisting with the hyperplasia. This makes the lesion even more alarming.

On the opposite side of the picture, however, Novak[2] has reported eighteen cases of atypical endometrial changes, eight of which had curettage alone and have remained well for from one to twenty-one years. Four of these eight were young women.

There is, then, no definite proof that adenomatous hyperplasia *per se* is necessarily a pre-malignant lesion. We know that different parts of the endometrium will react differently to estrogen over-stimulation—some areas showing simple cystic hyperplasia while others show the adenomatous type of overgrowth. Both of these will often respond to hormonal therapy. Even some atypical hyperplasias are capable of regression to normal endometrium if given amounts of progesterone at the proper time.

No one is agreed at just what point in the progress of the disease the pathology must be termed pre-malignant and irreversible.

Another point of issue is just what are we preserving if we do take a chance and leave the uterus in. As I have mentioned, this is done only in the case of young women in the hope that they will eventually have children. Yet all investigators agree that this atypical endometrium is attended by a high degree of sterility. In Speert's[6] study of fourteen young women with carcinoma of the endometrium, the most recent pregnancy among all fourteen had occurred fourteen years previously. Hertig also found sterility a concomitant factor. He further studied many of the resected ovaries in these cases and found a total absence of corpora lutea or albicantia in most of them. What then are we saving when we leave in a uterus with such an endometrium? At best we are saving a non-malignant organ which in all probability is incapable of carrying on its reproductive function; at the worst, an organ which is, or can, become pre-malignant.

From the small number of cases of atypical hyperplasia in young women reported to date, we can draw some fairly sound conclusions. We know that these patients almost always have a low degree of fertility. We have learned to recognize certain pathologic warning signs in tissue studies. What we do not know is which endometrium showing this type of picture will return to normal and which will continue on to undisputed malignancy.

Conclusions

With these facts in mind, and within the limited scope of our knowledge to date, the only possible rationale of treatment is an attempt to treat the disease as conservatively as possible. This means a trial of adequate hormonal therapy aimed at opposing the excessive estrogenic stimulation and restoring the normal cyclic hormonal balance. Curettage must be repeated at three-month intervals—no longer. If the disease is persistent, and especially if atypia becomes more pronounced, total hysterectomy is the procedure of choice. It is at this point that the decision to remove the uterus must be made and effected promptly. By so doing, a total hysterectomy is usually enough of a procedure. To delay further in the hopes of giving the uterus "another chance" may mean the difference between whether you can conserve the ovaries or not. To delay the interference in the progress of the atypia until a definite malignant change has occurred, condemns the patient to the added bilateral oöphorectomy with its concomitant climacteric.

Surgical Injuries of the Ureter

Presented as an Inaugural Thesis before the Minneapolis Academy of Medicine on October 21, 1957.

WILLIAM E. PRICE, M.D.
Minneapolis, Minnesota

A MAJOR complication of surgery on the lower abdominal viscera and perineum is accidental injury of one or both ureters. The incidence of such occurrences in gynecologic surgery is estimated at about 2.5 per cent of operations for nonmalignant disease and up to 30 per cent of radical dissections for cancer (St. Martin).[1] The need for frequent discussions of the prevention, recognition and treatment of these lesions is obvious since this incidence is approximately the same as it was thirty years ago.

The following presentation deals largely with the analysis of twenty-nine cases of ureteral injury seen in private Minneapolis hospitals between 1946 and 1957. The majority were treated by Dr. Edgar A. Webb and Dr. Baxter A. Smith. Twenty-three cases of unilateral injury and six cases of bilateral injury were encountered.

Prevention of ureteral injury is much simpler than the cure. Surgeons operating on the female genitalia and lower colon should be keenly aware that such injuries can occur even when the operations are conducted by the most experienced operators. Preoperative investigation of the urinary tract by excretory urography and retrograde pyeloureterograms in patients where difficulty is anticipated will demonstrate the functional capacity of each kidney and delineate deviations in the normal course of the ureters. The preoperative passage of large-caliber ureteral catheters is probably the most effective method of prevention and will aid considerably in later identification and avoidance of the ureters. Every surgeon should be familiar with the normal anatomic relationships of the ureters and should realize that most injuries occur where the ureter crosses the iliac vessels and where the ureter is in close approximation to the uterine artery.

Once an ureteral injury has been discovered, the patient or his relatives should be informed of the condition and the treatment necessary for correction should be initiated. Although such injuries are recognized complications of pelvic surgery, an injudicious word by a consultant or hospital employe may potentially lead to medicolegal action. No

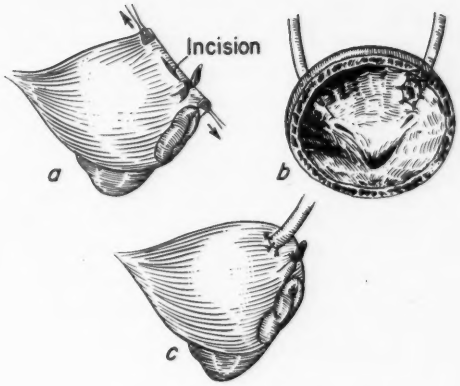

Fig. 1. Ureteroneocystostomy.

● *The prevention and management of ureteral injuries is of interest to everyone who performs abdominal and/or pelvic surgery. Here is an excellent and practical account of this subject.*

liability is incurred with a patient properly informed and correctly treated.

Ureteral injury occurs by clamping with a hemostat, ligating or suturing, angulation, partial or complete division, segmental resection and extensive stripping with subsequent ischemic necrosis. The resulting effect on the function of the involved kidney is of paramount importance. Findings and symptoms depend upon whether the injury is unilateral or bilateral, whether the occlusion is partial or complete, whether urinary drainage is intraperitoneal or extraperitoneal and whether infection is present or absent. (Creevy).[2]

Total	29

Original diagnoses which brought patients to operation and subsequent ureteral damage are listed in Table I. Original operations during which ureteral disruption occurred are listed in Table II. Various types of hysterectomies accounted for more

than half of the cases. Ureteral injury probably is more likely during difficult pelvic dissections attended by excessive bleeding and poor visualization of structures. Ureteral identification by means of inlying catheters at times such as this can be reassuring to any surgeon.

Immediate recognition of ureteral injury provides the most opportune time for repair. The appearance of an inlying catheter in the operative field, finding the severed proximal end of a ureter actively discharging urine, observing a ligature around the ureter or a hemostat clamped across the ureter indicate that injury has occurred. The surgeon should enlist the aid of an urologist who can help to identify the exact site of the injury quickly by passing ureteral catheters cystoscopically and who can advise with the ureteral repair and postoperative care. With an 8 French splinting ureteral catheter in place from the renal pelvis to the urethra, ligating sutures may be removed, incisions may be closed and elliptical end-to-end anastomoses may be performed. The ureteral catheter is anchored to an inlying urethral catheter and left in place for seven or eight days.

TABLE III. SYMPTOMS AND SIGNS*

2. Pain	3
3. Fever	3
4. Anuria and uremia	3
5. No symptoms	3
6. Abdominal distention	2
Total	26

*Observed when the ureteral injury was not recognized immediately.

A word of caution is given regarding intentional ligation of an injured ureter, a procedure to be condemned except in rare instances. Preliminary knowledge of the functional capacity of the opposite kidney is necessary and attempts at obtaining this information at operation under anesthesia are notoriously unreliable. Complete occlusion of a ureter to a noninfected kidney will cause hydronephrotic atrophy but similar treatment where previous infection exists may lead to urinary sepsis from infected hydronephrosis or pyonephrosis. Also, ligating sutures have been known to come loose with subsequent urinary fistulization. Urinary diversion by ureterostomy or nephrostomy is preferable to intentional ureteral ligation.

If the ureteral injury is not recognized immediately, characteristic symptoms and signs may appear later. Some injuries remain asymptomatic.

TABLE IV. REPARATIVE OPERATIONS

		Failures
1. Ureteroneocystostomy	10	0
2. Elliptical end-to-end anastomosis	6	3
3. Tubular bladder flaps	3	0
4. Deligation and ureterolysis	6	2
5. Vesicoureteroplasty	3	1
6. Cystoscopic fulguration of fistula	3	1
Total	31	7

Table III lists clinical findings encountered in our patients. Urinary leakage is usually vaginal but perineal and abdominal fistulae also occur. The finding most deserving of prompt attention is complete anuria in the early postoperative period. In such cases, the patency of the ureters should be determined by ureteral catheterization. Urinary diversion may be lifesaving if obstructive anuria is present.

TABLE V. NON-REPARATIVE OPERATIONS

1. Nephrectomy—primary	5
secondary	3
2. Intentional ureteral ligation	2
3. Emergency ureterostomy	2
4. Emergency nephrostomy	1
Total	13

Prompt urologic investigation is always necessary where ureteral injury is suspected. Preservation of functioning renal tissue is of prime importance and the fallacy of waiting for ligatures to dissolve or fistulae to close spontaneously has been demonstrated repeatedly. Accurate localization of the injury and appraisal of renal function are the chief prerequisites to adequate treatment.

Operative treatment of ureteral injuries may be classified into reparative (Table IV) and nonreparative (Table V) procedures. A total of forty-four definitive operations have been performed on our twenty-nine patients. The principals of treatment may be summarized as follows: (1) use of fine, absorbable sutures, (2) avoidance of tension on suture lines, (3) adequate tissue drainage with rubber drains, and (4) routine use of chemotherapeutic drugs. Splinting catheters are not employed as often as was formerly believed necessary (Hamm and Weinberg, Webb et al).[3-5] They are difficult to manage, lengthen the period of hospitalization and

encourage the development of strictures and persistent urinary infections.

Ureteroneocystostomy*

This procedure is feasible if sufficient ureteral length above the point of injury can be obtained to reach the bladder without tension. Ten successful operations of this type have been done, five without the use of splinting catheters.

Case 1.—A fifty-seven-year-old woman entered the hospital for abdominal enterocele repair. Preliminary ureteral catheterization was successful only on the right side; obstruction was met in the left intramural ureter. This was presumed due to scarring from a previous hysterectomy for fibroid uterus. During the operation, the left ureter was extensively dissected and bleeding was troublesome. Postoperatively, she had left lower abdominal pain and on the twelfth day vaginal leakage of urine occurred. An excretory urogram showed bilateral hydronephrosis with marked delay in the function of the left kidney. Retrograde pyeloureterograms demonstrated a left uretrovaginal fistula. Twenty-six days following the original operation, a left ureteroneocystostomy was performed. The ureter was found to be markedly dilated and the region of the fistula was encased in scar tissue. The ureter was severed just above this point and reanastomosed to the bladder through a small incision in the lateral wall. The full thickness of the ureteral wall was sutured to the bladder mucosa with 0000 chromic sutures. Supporting stitches were placed in the bladder and ureteral adventitia. A Penrose drain was left at the anastomosis site. No splinting catheter was used. An inlying urethral catheter provided urinary drainage for eight days. Some leakage of urine occurred from the incision for seven days and then ceased. Urinary infection was never bothersome. An excretory urogram nine months postoperatively was normal.

Elliptical End-to-End Anastomosis

This method is useful both for re-establishment of ureteral continuity after immediate recognition of ureteral division and for later repair. The edges of the ureter should be trimmed obliquely to provide a long suture line to discourage stricture formation. Failures have been attributed to urinary extravasation with subsequent periureteral fibrosis.

Case 2.—A sixty-nine-year-old man had the left ureter divided during an anterior resection of the sigmoid colon for adenocarcinoma. Cystoscopically an 8 French catheter was passed from the distal into the proximal ureteral segment, the edges of the ureter were trimmed obliquely and anastomosed with 0000 chromic sutures. The splinting ureteral catheter was brought out through the urethra. It was removed on the seventh postoperative day. Five months later his urinalysis was negative and an excretory urogram was normal.

Case 3.—A thirty-four-year old woman had a large endometrial cyst removed from the right broad ligament. The right ureter was divided where it stretched over the cyst. End-to-end anastomosis was done over a splint brought out through an opening below the suture line to the abdominal wall. Persistent urinary leakage and pyelonephritis occurred postoperatively. An excretory urogram showed a normal left kidney, marked stasis and hydronephrosis of the right kidney with ureteral dilatation to the pelvic brim. The caliber of the middle and lower portions of the ureter was diminished. A diagnosis of extensive periureteral fibrosis was made and an attempt

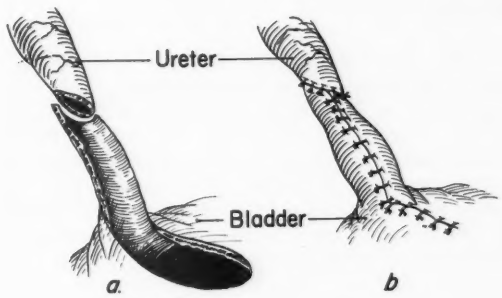

Fig. 2. Tubular bladder flap.

was made at secondary ureteral repair by dissecting the ureter out of the surrounding dense scar tissue. This also met with failure from urinary sepsis and fistulization. Right nephrectomy was performed eight months after the original injury had occurred.

Tubular Bladder Flap

Originally described by Boari and later revived by Ockerblad,[6] this operation makes possible the reconstruction of a long lower ureteral defect. A flap of anterior bladder wall is elevated with a broad base attached laterally to preserve blood supply. A tube is fashioned out of the flap which is anastomosed obliquely to the proximal ureteral stump.

Case 4.—A forty-two-year-old woman had no urinary output following a tedious bilateral oöphorectomy for endometriosis. Attempts at ureteral catheterization met obstruction in the left intramural ureter and the right catheter passed into the peritoneal cavity. Abdominal exploration showed excision of extensive segments of both pelvic ureters. Bilateral ureterostomies *in situ* were performed. Eighteen days later, after her general condition had improved, bilateral tubular bladder flaps were made and anastomosed to the proximal ureteral stumps. Her postoperative course was uneventful. Two years later the urinalysis was negative and an excretory urogram was normal. A retrograde cystogram showed saccular pro-

*See page 567, Fig. 1.

trusions of the bladder wall corresponding to the tubular flaps with free vesicoureteral reflux. She had no clinical symptoms, however, referable to this reflux.

Ureteral Deligation

In the early postoperative period, extensive attempts at deligating the ureter in patients already in incipient shock from long surgical procedures are attended by high mortality rates. Emergency urinary diversion is better judgment, followed later by ureteral repair. In selected cases, however, this procedure is feasible and prevents subsequent morbidity.

Case 5.—A thirty-six-year-old woman had the right ureter ligated during a vaginal hysterectomy. The injury was recognized immediately. Cystoscopy was performed on the operating table and while the urologist probed the ureter with a catheter, the surgeon removed the occluding suture. The catheter was passed to the renal pelvis and left in place for seven days. Three months later cystoscopy showed normal indigo carmine appearance from the right ureteral orifice.

Case 6.—A forty-eight-year-old woman had vaginal leakage of urine immediately following panhysterectomy. Her condition was good. An excretory urogram and bilateral retrograde pyeloureterograms showed slight right hydronephrosis, marked left hydronephrosis and dilatation of the ureter with considerable medial angulation of the lower portion. The abdomen was reopened, the left lower ureter was found caught in a reperitonealization suture which was removed and a splinting catheter was passed from the bladder to the left renal pelvis. The catheter was removed on the seventh postoperative day. Two months later the urine was normal and cystoscopic examination showed a good indigo carmine excretion bilaterally.

Vesicoureteroplasty

Dr. Baxter Smith suggested this procedure by which intramural and juxtavesical ureteral strictures may be corrected. The bladder is opened and the roof of the terminal ureter and overlying bladder wall are incised to a point above the stricture, thus incorporating the ureteral stricture into the bladder lumen. The edges of the ureter are sutured to the bladder mucosa. Splinting catheters have been employed but can probably be eliminated. The one failure in our series of three operations was in an instance with concurrent ureterovaginal fistula.

Case 7.—A forty-eight-year-old woman was anuric and became progressively uremic for six rays following panhysterectomy for cystadenocarcinoma of the ovary before urologic consultation was requested. The patient was acutely ill, the abdomen was markedly distended and the right kidney was palpable. The left ureter was obstructed to a catheter passed cystoscopically; a catheter passed up the right ureter entered the peritoneal cavity.

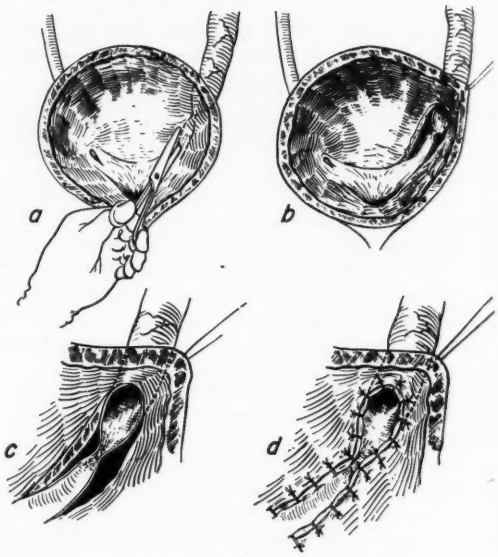

Fig. 3. Vesicoureteroplasty.

Right nephrostomy and drainage of urine from the peritoneal cavity were performed, followed in seventeen days by deligation of the left juxtavesical ureter. A small incision in the ureter was closed and a splint was left in place. The left ureter was apparently well healed when right nephrectomy was performed six weeks following the ureteral injuries. However, a left lower ureteral stricture subsequently developed which was corrected by vesicoureteroplasty one year later. Three years postoperatively the left kidney was normal by excretory urogram. She still has occasional episodes of pyelonephritis.

Cystoscopic Fulguration of Ureterovaginal Fistula

This has been employed successfully in two cases. One case similarly treated elsewhere and subsequently seen by us was a failure. The vaginal aspect of the fistula should be surgically excised.

Case 8.—Ten days after a difficult panhysterectomy for ovarian cyst, this forty-one-year-old woman had chills, fever, left renal pain and vaginal urinary leakage. Urologic investigation showed narrowing of the left juxtavesical ureter with an ureterovaginal fistula just above the stricture. Repeated ureteral dilatations relieved the stricture but the fistula persisted. Three months after the injury the fistula was visualized and fulgurated with an 11 French McCarthy infant panendoscope introduced

into the lower ureter. The tip of the electrode broke off but it was fortunately retrieved with small cystoscopic grasping forceps. The vaginal side of the fistula was excised. Urinary leakage promptly subsided. Four years later an excretory urogram was normal.

Primary Nephrectomy

Occasionally nephrectomy after ureteral injury is indicated when: (1) circumstances such as age, debility, concurrent disease and renal damage make the risks of repair impractical and (2) the opposite kidney is normal.

Case 9.—This forty-five-year-old woman had the right ureter completely occluded during panhysterectomy for endometriosis. She gave a long past history of psychoneurotic complaints. Right kidney pain, chills and fever had been occurring for nineteen postoperative days before urologic consultation was requested. The right kidney was nonfunctioning and the left kidney was normal by excretory urography. A hight ureterogram showed complete obstruction at eight centimeters. Right nephrectomy was performed. She has since been institutionalized for mental illness.

Summary

Twenty-nine cases of accidental surgical injury to the ureters have been analyzed and representative cases have been summarized. Methods of prevention, recognition, diagnosis and treatment of these injuries have been discussed.

Discussion

DR. ROBERT TENNER: How do you destroy the blood supply of the ureter? What is the blood supply?

DR. PRICE: The ureteral blood supply is derived from three sources: (1) renal artery; (2) iliac artery; (3) vesical arteries. There are rich anastomoses between these branches in the ureteral walls. Extensive ureteral adventitial dissection is probably necessary for ischemia to develop, although why it does not always occur under these circumstances is not readily apparent.

DR. ROY SWANSON: In case of doubt can you open the bladder and slip ureteral catheters in and find injury?

DR. PRICE: Yes. Ureteral catheterization on the operating table either through a cystotomy or by cystoscopy is the best way to locate ureteral injuries that might be suspected during an operation.

DR. SWANSON: This paper is most instructive. I would like to add a point that has helped me. In difficult cases where an injury to the ureter is suspected, the bladder can be opened, and catheters inserted into both ureters without danger. This procedure will save you a lot of worry and possibly later surgery.

DR. EDGAR A. WEBB: When the urinary tract is injured during the course of an unrelated surgical procedure, and this injury most frequently involves the ureters, it is important that the attending physician make this information known to the patient immediately. If the patient's condition doesn't permit him to comprehend the nature and significance of the injury, then a concerned relative should be informed. Urologic consultation should be sought immediately when such injury occurs. Informing the patient completely and securing consultation immediately, accomplishes a great deal in maintaining satisfactory public and professional relations with the patient.

The reason for these immediate steps is that patients are often first informed of the injury by others than their physicians. Patients and relatives of patients are often inclined to assume that some incompetency has brought about the complication and are, therefore, hostile toward the physician. This is the substance from which malpractice suits are often developed.

The procedure of vesico-ureteroplasty such as illustrated so beautifully on Doctor Price's slide, should perhaps be referred to as the Smith Operation or Procedure. To my knowledge this particular plastic procedure is not described elsewhere and I believe that Doctor Baxter Smith adopted the principal to the problem of the strictures of the ureter in the juxtavesical or intramural portion.

Since we have given up the use of catheters for splinting repairs in the ureter and in the ureteropelvic junction and since we have abandoned nephrostomy and pyelostomy drainage by catheter the patients seem to get along better. Their hospital stay is shortened; they are more comfortable, and the urine returns to normal more quickly than when these splints are used.

Doctor Price has presented a well organized, timely and detailed report on surgical injuries of the ureter.

Urinary Diversion: Uretero-Sigmoidosto

A brilliant review and detailed study of a life-saving procedure.

DIVERSION of the urinary stream is a palliative or corrective necessity in many clinical conditions. Generally, it is a surgical problem based on many factors, leaving much to be desired in the end result, no matter what procedure is used to divert the urinary stream. Three essential conditions must be satisfied to make urinary diversion an ideal operative procedure: (1) Correction of the primary pathological problem or disease. (2) Preservation of normal renal function (if present prior to surgery). (3) Continence of the urinary and fecal stream.

Many procedures have been devised since attempts at such surgery first began to satisfy all three conditions, and all have been met with inconstant success. Indications for such an operation are not numerous but steadily increasing with ability to perform successfully more extensive and radical surgical procedures.

Urinary diversion is used in several conditions:

1. Exstrophy of the urinary bladder and epispadias.
2. Inoperable vesical-vaginal fistula.
3. Intractable interstitial cystitis, or post inflammatory fibrosis with vesical contracture.
4. Advanced vesical tuberculosis when all other forms of treatment fail.
5. Crushing injuries to the pelvis with extensive destruction of the male urethra, and/or bladder.
6. Advanced destructive and irreparable disease of the urethra ("watering pot perineum").
7. Extensive scarring or other irreparable damage of pelvic ureters due to surgery or radiation therapy.
8. Cystectomy for carcinoma of the urinary bladder or urethra.
9. Pelvic evisceration for extensive carcinoma of the pelvic organs.
10. Atonic bladder with ureterectasis with or without reflux.
11. Neurogenic vesical or sphincteric dysfunction.

This paper is directed primarily to carcinoma of the bladder in the male patient.

Principles and Historical Background

Search for a substitute for the urinary bladder is centered largely around the use of various portions of the bowel as reservoirs and conduits. Many years of experience involving experimental and clinical trial and error have demonstrated the real difficulties of providing a functional reservoir, and have elicited the factors responsible for dysfunction of the substitutes. Obstruction to urine flow, renal infection, and absorption of urinary constituents are the main problems. A true substitute for the bladder should protect the kidneys from infection, include non-interference with body fluid and electrolyte balance, permit intermittent evacuation of urine at reasonable intervals under voluntary control (and without the use of catheters or appliances) compatible with a normal social and physiologic existence.

An ideal ureteral-intestinal anastomosis must be based on the following principles: (1) Diversion of the fecal stream from the bowel reservoir to prevent ascending infection. (2) Elimination of obstruction at the site of anastomosis by a transplantation technique by the direct method. (3) The bowel reservoir receiving the diverted urine should not be too large. (4) The bowel reservoir

should be either empty continuously or be emptied frequently, preferably by physiologic rather than mechanical means.

Proximal colostomy and implantation of the ureters into an excluded rectosigmoid pouch, a transplantation of the ureters into an isolated ileal segment or sigmoid loop appear to be operations with the potential to satisfy these criteria. We will present two cases of the first procedure using the modification outlined by Gersuny[1,8] in 1898 and recently by Lowsley and Johnson[3,4,5] avoiding the use of a colostomy.

Attempts to divert the urinary stream from a diseased bladder are not new. The first report of such an experimental and clinical procedure is said to have been that of Dr. John Simon in 1852.[2] Following experimental studies in dogs, he attempted clinically to divert the urine through a fistulous tract from man exstrophy of the bladder to the rectum. The procedure was performed on two patients and one died from peritonitis and the other from multiple urinary calculi and renal insufficiency, one year after the operation. In 1878, Thomas Smith tried a direct ureteral transplant into the bowel.[2]

It has been noted that the major difficulties associated with uretero-intestinal implants are due to stricture at the point of the anastomosis and to ascending urinary tract infection. The obstruction to the drainage of a hollow viscus anywhere in the body predisposes to infection. The end result with such a situation is hydronephrosis and hydroureter with pyelonephritis, and progressive renal insufficiency. Numerous attempts have been made to establish a valve-like mechanism at the site of the anastomosis for the purpose of preventing reflux of the intestinal contents into the ureter. These attempts have not been successful in preventing reflux and subsequent occurrence of an ascending infection. The success of diversional urinary tract drainage might well be dependent upon the formation of an artificial vesical that could be completely emptied at periodic intervals and that would not be constantly contaminated by the presence of fecal material.[6] The most ideal substitute would be an isolated segment of the bowel. Tizzoni and Foggi in 1888,[2] isolated a segment of ileum, closed one end and sutured the other end to the neck of the bladder, and implanted the ureters into this pouch maintaining sphincteric control and allowing the normal vesical sphincter to remain intact. It is seldom possible to remove the bladder and retain the vesical sphincter in neoplastic diseases, therefore the use of this operative procedure in man is necessarily limited, for such tumors frequently involve the trigone and require more extensive procedures and total cystectomy is a prerequisite to any anticipated cures.

In 1906 VerHoogan[2] formed a substitute urinary reservoir by using the ileal-cecal region with the appendix as a "urethra," hoping to make use of the muscular activity of the abdominal wall as a sphincter to control urinary leakage. In 1950, Bricker and Eisman[6] reported two cases in which the terminal segment of the ileum and cecum

were utilized for the vesical pouch. The ureters were transplanted into the ileal segment and a cecostomy was performed through which a catheter could be passed for evacuation of the newly formed bladder. In 1952, Merricks[7] described five cases in which a total cystectomy was performed and the ileal-cecal valve remained competent as a sphincter, using the cecum and terminal ileum for the new bladder.

Review of Procedures[2]

A review of procedures for urinary diversion seems appropriate at this time to develop the background of the Gersuny procedure, which we believe is an acceptable procedure for urinary diversion in some cases. Ureteral diversion of the urine may be grouped into the following classifications:

1. Non-intestinal
   a. To the skin
   b. To other structures
      (1) Urethra
      (2) Vagina
      (3) Fallopian Tubes
      (4) Uterus
      (5) Blood Vessel
      (6) Meninges of the spinal cord
2. Intestinal
   a. Into an excluded portion of the tract
      (1) Completely excluded portion
      (2) Partially excluded portion
   b. Into the intact tract

Non-intestinal methods of ureteral implantation are no more than temporizing measures and implantations to other structures are obviously without merit. The intestinal tract is therefore the obvious organ for a urine reservoir.

1. Implantation of the ureters into a completely excluded portion of the intestinal tract
   a. An artificial bladder made from the small gut
      (1) Placed under control of the vesical sphincter, experimental only (Tozzini and Goggi in 1888)
      (2) With the end brought out through the anal sphincter (Cuneo, 1911)
   b. An artificial bladder made from the entire rectum
      (1) Ileal-sigmoidostomy (Mauclaire, 1894)
      (2) *With the sigmoid drawn through the anal sphincter (Gersuny, 1898[1,8])*
      (3) With the excluded rectum made to communicate with the urethra for control by the sphincter (Lemoyne, 1912)
   c. An artificial bladder made from a pouch of the anterior rectum (Latheisen, 1899)
   d. An artificial bladder made from the ileal cecal region, the appendix serving as a urethra (VerHoogen, 1908)
2. Implantation of the ureters into a partially excluded portion of the intestinal tract
   a. The blind pouch of the lower ileum emptying into:
      (1) The ileum (Nagano, 1901)
      (2) The cecum (Goldenberg, 1904)
      (3) The transverse colon (Moskowicz, 1909)
      (4) The sigmoid (Berg, 1907)
   b. A blind pouch of short circuited loop of the sigmoid (Boreliaus, Berglund, 1903)
   c. A blind pouch of the sigmoid emptying into:
      (1) The lower sigmoid (Mueller, 1903)
      (2) The rectum (Muscatello, 1904)
   d. A blind pouch of the upper rectum (Descomps, 1909)

Comments on Common Procedures

1. *Cutaneous Ureterostomy.*—This is the most unesthetic and annoying procedure of all the diversionary methods. Continual problems of skin sensitivity to contact cement and reaction of the abdominal skin to pooling of urine from the ostea, stricture formation of the ostea, abscesses along the ureter, calculi, and/or retraction of the ostea beneath the skin surface coupled with odoriferous and cumbersome appliances doom the patient with this procedure to social solitude and economic and renal failure.

2. *Ureterosigmoidostomy.*—This requires no external appliances, but the pathophysiological shortcomings are many, chiefly those of regurgitation of mixed feces and urine from the bowel to the kidney because of the variation in rectal and ureteral pressures terminating in chronic pyelonephritis, progressive uremia and hyperchloremia. Pyelonephritis from obstruction and ascending infection is a common cause of tubular damage although back pressure alone may suffice in some cases. Hyperchloremic acidosis is due to absorption of the urinary constituents in the presence of renal tubular damage.

Although the role of the kidney in the acidosis of ureterosigmoidostomy has received considerable attention, the frequent clinical observation of reversal of the acidosis by rectal tube drainage is evidence against this concept. Other contradicting evidence is that greatly elevated serum chloride levels are seen with near normal non-protein nitrogen levels. Frequency of emptying the sigmoid of urine and voluntary low chloride and high water intake may explain some instances of patients who do not develop acidosis. The nature of the mucosa in the rectosigmoid and

the mechanics of flow over the mucosa must also be a factor. There may be a change of absorption function of the sigmoid mucosa after prolonged exposure to urine.

Patients with diversion of the urine to the colon regardless of how much colon is used or if only one ureter is transplanted, may lose potassium.[9-12] Hypopotassemia[11] (although it causes renal insufficiency and may produce weakness, lethargy and anorexia, hardly distinguishable from terminal cancer) is often a relatively asymptomatic disease. The union of the urinary and fecal streams will produce ascending infection and although the methods of Cordonnier and Nesbitt[13] are created to avoid such problems, nevertheless the problems are still present. Stricture formation at the site of the anastomosis of the ureter to the bowel is not uncommon. The patient must avoid hyperchloremia and acidosis by a low salt or salt-free diet and alkalizers. In addition, the problem of catheterization at periodic intervals during the day to avoid collection of urine in the rectum and thereby prevent absorption and also regurgitation is an inconvenient and hazardous procedure. Except when rapid and continuous run-off of urine occurs from a short segment, ureterosigmoidostomy should probably be abandoned.

3. *Isolated Segment of Cecum.*—The operation of Merricks and Gilchrist[7] creates an artificial bladder using the cecum and proximal end of the colon with the ileal-cecal valve maintained intact as a sphincter mechanism with the ostea leading to the abdominal wall. It can produce the problem of the cutaneous ureterostomy type of diversion with skin reactions to urine and cement, and also may or may not require an abdominal collecting mechanism, although the valve functions in many patients.

4. *Diversion to an Isolated Segment of ileum (Bricker Operation).*—This procedure also places an ostium on the patient's abdomen without control of the urinary stream subjecting the patient to appliances and skin reactions as well as the formation of large amounts of mucus, and/or calculi. Regurgitation to the upper urinary tracts is not totally absent and a constant source of infection is present.

Bricker[6] reported 118 pelvic exenteration and thirty-two other bladder substitution operations with an operative mortality of 3 per cent. Postoperative pyelonephritis occurred in 20 per cent. Normal upper tracts or minimal hydronephrosis was seen six months postoperatively in 86 per cent. Hyperchloremic acidosis was not observed. The operation fulfills in many respects an ideal operation for urinary diversion and bladder substitution: (1) Mechanical and technical simplicity make it practical to combine with major resection without staging. (2) Isolation of sigmoid from fecal stream decreases the chance of ascending infection. (3) The wide open external stoma with absence of sphincter mechanism decreases the chance of back pressure and reflux up the ureters. (4) Segments evacuate promptly through peristaltic action and are always relatively empty. (5) Mucosa-to-mucosa technique in performing ureteral intestinal anastomosis lowers the incidence of obstruction and thus of hydronephrosis and pyelonephritis. (6) The amount of absorption through intestinal mucosa is of no clinical significance.

5. *Diversion to the Proximal Colon.*—This procedure has been discarded after the demonstration by Boyce of the tremendous absorptive powers of the colon distal to the most proximal portion of the colon adjacent to the cecum.[14,15]

6. *Diversion to the Isolated Rectosigmoid with Diversion of the Fecal Stream by an Abdominal Colostomy.*—This procedure described by Kinman, Sauer, Huston and Mellick[16] demonstrated a definite absence of hyperchloremia or azotemia, and the control of the new urinary sphincter without incontinence of the urinary stream.

The essential features of this procedure are the permanent separation of the urinary and fecal streams, relative simplicity of execution and good functional results accomplished by construction of a diverting single-barrel colostomy at the junction of the descending and sigmoid colon and the use of the distal rectosigmoid colon as a bladder substitute to which the ureters are anastomosed. Patients are completely continent of urine during the day but slight incontinence at night is noted when overly tired. Incidence of acute pyelonephritis is less to none. Blood urea nitrogen levels remain normal. Daily irrigation of the colostomy allows control of bowel function and colostomy bags are not always necessary. Rectograms show surprisingly low pressure gradients and sharp peaks in each curve correspond with an urge to

empty the rectum so that such sensation should be adequate protection against excessive pressures within the bladder substitute. The surface of the colon exposed to urine is limited by the dimensions of the rectosigmoid bladder substitute.

Mauclaire[17], sixty-four years ago suggested this procedure and others have since advocated it (Kroenig,[2] Creevy[18]). Even today, the best series of ureterosigmoidostomy has 45 per cent incidence of hyperchloremic acidosis, therefore separation of the urinary from the fecal stream has been a logical step to take even though the goal of urinary or fecal continence must be abandoned.

Kinman et al[16] observed rectal defecation pressures of 180 cm. of water to as high as 280 cm. of water. The major portion of this pressure is due to the action of the diaphragm and abdominal muscles when the subject strains to defecate. This force is of course transmitted to the ureter as well as the bowel. Diversion of the colon by colostomy makes straining unnecessary. Secondly, fecal material is propelled to the rectum under some 80 cm. of pressure by peristaltic contractions extending along the entire length of the colon with alternate contraction and relaxation and shortening and elongation of one segment after another, progressively toward the anus. Colostomy blocks these progressive waves. Patients with a rectal bladder void at lower pressure relying largely on local bowel contraction for emptying, and also the need for abdominal straining is minimized because of the liquid content of the rectum. The voiding pressure in the isolated rectum will usually be less than 30 cm. of water.[12]

Acceptance of colostomy by surgeon and patient alike following radical operations on the rectum is well known. Colostomy should also be accepted as the means of avoiding many of the complications of ureteral-intestinal anastomosis. Ureteral-intestinal anastomosis has become a clinically less popular procedure, particularly when one considers the other methods of urinary diversion, ureterostomy, nephrostomy, and particularly the cecal bladder or ureterostomy *via* an isolated ileal loop. One is faced with two alternatives—a patient will have to choose between urinary incontinence from the stoma in the abdominal wall, collecting the urine by catheter or bag, or a colostomy which must be irrigated once a day. Even though feces are more repugnant to the patient than urine, with proper care a colostomy does provide a minimum of discomfort. We are not prepared to decide which arrangement will prove more acceptable and successful clinically, but the rectal bladder with sigmoidostomy offers a more physiological and practical substitute for the normal urinary bladder.

The urine has produced a minimal amount of reaction in the isolated rectosigmoid and although not ideally suited as a substitute bladder, yet the possibilities were explored as early as 1898 by Gersuny[1] as reported by Foges[2] in 1898 and 1899.

7. *Vesical Rectostomy.*—This procedure was first described by Maydl[19] in 1894 in which the trigone with the ureteral orifices intact was implanted into the anterior rectal wall. This had been done on numerous subsequent occasions by other authors. This procedure might be applicable to the patient with an exstrophy of the urinary bladder, or interstitial cystitis of intractable type, or severe bladder injury. However, for a carcinoma of the urinary bladder in which cystectomy is the procedure of choice, this could not be accomplished and achieve the primary purpose of attempting to eradicate the original pathology.

8. *Gersuny (Lowsley-Johnson) Operation.*—The thinking with regard to an answer which would most completely encompass and solve the problems of uretero-intestinal anastomosis lies in the Gersuny operation, diversion of the urine to the isolated rectosigmoid with diversion of fecal stream to the perineum avoiding abdominal colostomy.

Hinman and Weyrauch[2] in their review of ureterointestinal implantation described Gersuny's original procedure. Using the completely isolated rectum as a urinary reservoir, Gersuny in 1898 devised an operation intended to maintain fecal as well as urinary continence. He first isolated the rectum and implanted the trigone into the divided rectal lumen after Maydl's method. The proximal sigmoid was then drawn through an opening made along the anterior margin of the anus and anchored within the anal sphincter so that this structure could actively control both the newly-formed bladder and the sigmoid which served as the new rectum. Revising the location of the orifices in 1912, Bayer[2] attempted separate urinary and fecal outlets using a common rectal sphincter bringing the proximal bowel posterior to the new bladder. Melinkoff,[2] in 1924, modified

Gersuny's technique by fashioning the skin of the perineum into a channel intended to serve as a urethra for the newly-formed bladder and believed this channel opening at a distance from the anus minimized the danger of ascending infection. It was not revived until Lowsley and T. H. Johnson [3,4,5] reported a case of a fifty-nine-year-old man with carcinoma of the urinary bladder upon whom a Gersuny type procedure was performed. In 1955, T. H. Johnson[3] reported a two-year, nine-month period of use of the Gersuny Operation in two cases of carcinoma of the urinary bladder. In essence, the scheme of the operation is: (1) Anastomosis of the ureters to the isloated rectum through an abdominal incision. (2) Dissection of the sigmoid mesentery to liberate and lengthen the sigmoid. (3) Through a perineal incision immediately anterior to the anus, a plane of dissection is carried under the external sphincter ani muscle to the rectal-vesical pouch. (4) The liberated sigmoid is drawn under the external sphincter ani muscle and out the perineum. The final result is two perineal openings—separate but adjacent. The anus or urinary outlet immediately posterior to the perineal sigmoid stoma or new rectum, both orifices encircled by and under the voluntary control of the external sphincter muscle.

Stonington and Eisman[20] reported five cases of patients with carcinoma of the urinary bladder utilizing this procedure.

Keefer and Lienke[13] report four patients with exstrophy of the urinary bladder in which this procedure has been used avoiding the usual complications of the usual diversionary procedures.

Advantages.—

1. A separate orifice for the urinary stream with voluntary control.

2. A separate orifice for the fecal stream with voluntary control and sensation.

3. Possibility of avoiding regurgitation or reflux of urine to the upper urinary tracts.

4. Avoiding absorption of metabolites on the basis of the use of the most unresorptive portion of the intestine.

5. Avoidance of an abdominal orifice and collecting appliances.

6. A bladder which could be subject to cystoscopic examination if necessary.

The Gersuny Operation potentially will meet the three conditions for an ideal ureterosigmoidostomy: (1) control of the primary pathological process, (2) preservation of normal renal function, (3) continence of feces and urine provides the patient with two "natural" orifices not requiring collection appliances. Physiologically, approximately a normal voiding pattern with control and holding of the urinary stream is possible and the same situation can conceivably exist with regard to the fecal stream, with a normal filling sensation and emptying reflex. The location of both orifices in the male approximates that which is present in the female only with the orifices transposed.

Disadvantages.—The disadvantages will only become apparent when this operation has been done many times by various operators in various centers with the main problem that of possible renal damage. Separation of the fecal stream from the urinary stream should abolish any possibility of infection, for in the isolated rectal segment the urine should eventually be sterile and can be maintained in that state with proper perineal care by the patient. Absorption of metabolites with distortion of the electrolyte pattern is avoided by use of the least resorptive portion of the colon.

Possible Postoperative Complications.—

1. Leaking ureteral anastomosis—prevented by use of direct mucosa-to-mucosa technique under direct vision, and placement of splinting ureteral catheters through an indwelling rectal tube which is fixed to the peri-anal skin by heavy silk sutures.

2. Bowel herniating through the open triangle made by ureter, rectal wall and pelvic brim is a possibility.

3. Redundancy of tissue at the new rectum. Redundant tissue in the new rectum is purely a cosmetic disadvantage and it has been eliminated by Sherman's method of plastic reconstruction as a secondary procedure.

4. Formation of adhesions.

(To be concluded in June issue)

Psychodynamics of Hospitalizati

● An understanding, relatively non-technical discussion of the Psychodynamics of hospitalization and nursing care—and a common-sensical constructive criticism of current trends in hospital care.

THE MOST casual observation of a person suffering from a physical illness will usually reveal something about his outlook on illness. The psychosomatic approach to medicine considers psychic and somatic symptoms as different aspects of one and the same disease. This approach is based on the fact of the interrelatedness of body and mind so that whatever affects the one inevitably influences the other. The particular focus of this paper is closely, thought not strictly, linked with the psychosomatic approach to physical disease. It is an attempt to explore the psychic response of supposedly normal individuals to hospitalization, physical illness, and pain. One of the basic assumptions underlying a psychodynamic approach to physical illness and hospitalization is that normal adults frequently adopt regressive behavior patterns as a result of this new distressing situation. Although the aim of this paper is a deeper penetration into the psychodynamics of physical illness and hospitalization in adult life, a preliminary study of the child's response to sickness and hospitalization is practically indispensable for reasons which should become apparent as the discussion progresses.

It is necessary to know the complexity of the phenomena that we are exploring. That cause and effect relationships may be perceived more readily, a distinction between the effects caused by physical illness and pain and those caused by hospitalization will be made. However, it is equally important to realize that both are anxiety-producing factors: hospitalization because it separates the patient from loved ones and familiar surroundings, and physical disease because it may cause discomfort, inhibit movements, or be a threat to "ego" development.

Sister Edith is Instructor in Psychiatric Nursing, The College of Saint Catherine, Saint Paul, Minnesota.

...ne Implications for Nursing

Presented before the St. Paul Unit of the National Council of Catholic Nurses, November 11, 1958.

Response of Children

The first anxiety-producing factor under consideration is the hospital experience. It is considered as a major source of anxiety because it separates the child from those he loves. Anna Freud refers to it as the "prototype of the first, short term separation from home."[1] The emotional response of a child to this situation is often referred to as separation-anxiety. Jessner and others found in studying 143 children, who had tonsillectomies and adenoidectomies, that the hospital experience had different meanings. Some experienced it as loneliness, others as a loss of protection and still others as total and complete abandonment.[2]

It is not unusual for the effects of a poorly handled hospitalization to produce in the child long-lasting separation anxiety which will definitely mark his personality development. Else Pappenheim and Mary Sweeney relate such an experience in describing Michael's first trip to the hospital to have his tonsils and adenoids removed.[3] Because Michael was only three years old his parents did not tell him anything about the hospital or about the operation; they thought that he would not understand anything anyway. They simply brought him to the hospital the morning of the operation and, after undressing Michael, his mother left him in order to take a message to her husband who was waiting outside in the car. When she returned she found that Michael was already gone, and she could hear his far-distant screams. After the operation, the hospital called the parents at home and told them that Michael was doing well and that they could come to get him the next morning. When Michael saw them the following morning he said, "You don't love me or else you would have come sooner." From this time on he was terrified when his mother left him, and the problem reached such proportions during his fourth year that it became necessary for him to receive psychiatric assistance. There were, of course, other factors which contributed to Michael's problem but the improper handling

of his hospitalization was certainly a significant one.

The separation problem in hospitalization of children may be intensified due to confinement. With the inhibition of movement there is additional frustration because the child can neither work off the excess energy caused by the anxiety-producing situation nor can he distract or express himself through play. One of the commonest ways for a child eighteen to thirty-six months old to protest separation from his mother is to plead for her return. (The encouraging thought for hospital personnel is that this wailing can not go on forever, for sooner or later another response will be initiated.[4])

There are additional problems resulting from hospitalization which should at least be identified in this discussion. For many children there are relationship problems because this may be the first time they have had a prolonged contact with anyone outside of their immediate family. There may be a new adult-child relationship with a nurse which may take the form of a substitute mother-child relationship. One thing is certain about these new relationships and this is that the child must live for a time with people who are strangers to him. If he is either an only child or a pre-school child, he may be confronted with a new form of social adjustment, that is, either forming new peer-relationships or being handled as one child among many other children. An older child's ego may be greatly threatened by being placed in a crib bed, particularly if he has some wishes to be a little child again. Regressive behavior patterns are frequently observed in hospitalized children. This regressive effect may be attributable either to hospitalization, to bodily illness, or to both. However, separation would appear to be one of the chief contributory elements, for the mother-child relationship directly influences the establishment of controlled behavior on the part of the child. He is able to face reality due to the support of the relationship with his mother. It is not at all unusual for a bowel-trained or bladder-trained child to lose this control within a hospitalization period and regress to a previous level of development, or for a weaned infant to return to bottle feedings. The regressed behavior always means that the child becomes more dependent on those in his surroundings and less self-sufficient.

Although the discussion of the effects resulting from hospitalization has not been an exhaustive one, we will now consider some of the psychological implications of pain and bodily illness on the life of the child.

It is believed that in infancy almost any tension, need, or frustration is experienced as pain. During the first few months an infant has practically no control of his response to stimulations either from without or from within, and excessive stimulations may be experienced as traumata.[1] Margaret Ribble points out that the infant's reaction to a primary tension state is predominantly a somatic or physiologic one, whereas in an adult the somatic aspect is not necessarily the chief component.[5] As the infant develops, pain becomes charged with a psychic meaning and the physiologic response is influenced or greatly determined by the mental interpretation of pain. Ordinary observation reveals that individuals have different levels of tolerance for pain. The analytic explanation for this fact is that the actual bodily experience of pain is not different but that the difference lies in the psychic significance attributed to pain. It is possible to observe the fact that bodily events begin to take on psychic meaning at at early age. For example, a child may be taken to a doctor's office for a blood count. The next time the child goes to the office for a treatment that is not painful, he reacts with identical distress. Another example is the response of distress that is experienced by many persons merely from the sound of a dentist's drill.

There are, in general, two behavior patterns which a sick child may adopt in meeting the physical demands of sickness. These responses have been referred to as changes in the distribution of psychic energy as a result of bodily illness. The first of these is a withdrawal from the external environment, a withdrawal which includes both things and people. The child loses interest in eating, playing, and talking to others. He is centering his energies on the inner world in which he is experiencing bodily distress. The second reaction is just the opposite of withdrawal; it is a behavioral response that makes greater demands on the external world. This reaction makes excessive demands on the affection and attention of others and wishes things to be used to alleviate interior distress. The dynamic explanation offered for this kind of reaction suggests a certain inability on the part of the individual to give his own body additional attention. As a child returns to his normal healthy state, the psychic energy be-

comes regulated once again, and while this is happening the child passes through a "cranky" phase.

Now the analytic interpretation of these two general responses to illness does not have to be accepted, but the observable behavioral patterns plus the disagreeable state in recovery are indubitable to anyone who has worked with sick children.

Changes in a child's emotional life during illness often result from changes in parental attitudes toward him. There is the ascetic parent who fears spoiling the child by giving him too much attention and who therefore resorts to leaving the sick child alone to "sleep out" his illness. There are many parents, the majority in fact, who become more indulgent during sickness than at any other time. They fondle the child, they drop disciplinary measures and give way to all requests. The mother spends more time with the child and, if he is a member of a large family, this may be a new experience for him. Being sick is for this youngster a rather pleasant experience.[1]

The experience of being nursed will also invite some changes in the child's emotional life. These changes can best be understood by reflecting upon the child's developing "ego." Ego development is understood in terms of mastery of bodily functions and the separation problem is slowly resolved as the child becomes more self-sufficient in caring for his own body. He is able to know himself, comprehend his own identity and know his own body apart from his mother's as he develops control over it and is able to care for it. A loss of control or even of independent caring for a part of bodily function is equivalent to a loss in ego development for the child. There is almost always a degree of regression present during a child's illness, for the most recent ego achievement is usually lost—inasmuch as a state of sickness is necessarily a more dependent one than that of health and forces the child to a preceding level of development. This can present a serious problem for a child who has built up resistance to a condition of passivity or for a child who has a strong leaning toward dependency and whose ego structure is very weak. This could be exemplified by the case of a child who had a baby brother born when he was one year old. This child was forced to become independent before he was emotionally ready for it. Since he still had infantile needs to be met, sickness afforded him the opportunity to be as dependent on his mother as he wanted to be—to be a baby again for a time.

The last point which we will consider is the psychodynamic aspect of surgical procedures. The chief concern here is the handling of the problem of fear of bodily injury. The psychoanalysts attribute a great deal of this to fear of castration. Anna Freud says that any operation "may serve as a focal point for activation, re-activation, grouping and rationalization of ideas of being attacked, overwhelmed (or) castrated."[1] The psychic significance is not in proportion to the seriousness of the procedure in reality but rather in relation to the phantasy about it. Jessner and others found in their study that the symbolic significance associated with tonsillectomy and adenoidectomy had been fostered by the parents of the children. For example, tonsils had been referred to as the focal point of "bad stuff" or as the source of all "difficulties." They also found other meanings, such as, giving birth, punishment, and exorcism.[2]

Adult Responses

The reflections that follow concerning some of the psychodynamic aspects of hospitalization, physical illness and pain pertaining to the normal adult are, for the most part, drawn from the preceding section on the child. The reason we have sought to approach the problem in this way is because most psychopathology in adult life is some form of regression to a child-like state. Now, it should, of course, be noted that we are dealing here with the presumably "normal" adult and not necessarily with a psychopathologic problem. But it is also imperative to consider and reflect on our observations that the normal adult under the stress of physical illness and pain and/or hospitalization frequently regresses to a preceding level of psychic development. Such a regression does not label him "psycho"; it simply implies that there is some psychological cause for his behavior. A mild degree of regression comes within normal range whereas exaggerated regression would, naturally, be abnormal. Although we do not consider this normal regression to be pathologic, it is necessary to turn to the field of psychiatry to gain an understanding of this process. Our approach from child to adult seems quite justifiable, for "logically any study of psychiatric disorders ought to put the child and his emotional illness first and then proceed to the study of disorders of later life where time, bringing added frustration, failure, disap-

pointment, infections, poisons, diseases and disintegration, has further complicated the problem."[6] By using this approach we move from a complex situation to a more complex one.

In discussing hospitalization for the adult, we shall follow the same plan used in the section on the child. The basic consideration will be similar, whereas the problem will be increasingly complex. The way in which an adult resolves his problems is dependent upon the way he resolved them as a child; he is influenced by a certain pattern which he established. If he has not established such a pattern and has therefore, a problem left unresolved from childhood, it will remain unresolved in adulthood.

Separation from parents was one of the principal problems of the child in hospitalization. By the time a person reaches adulthood it is supposed that separation from parents has been completed. This is not always the case; physically a person may be mature and independent, but emotionally he may be very immature. The mother figure represents security, well-being, protection and love to the child. As a child develops, his physical and emotional needs should be met simultaneously but this is not always so; hence, there may be a disproportion of development. Therefore, although physical separation may be complete, emotional separation may not be and may cause a person to feel insecure, frightened and unloved. Each time such a person is confronted with another separation he is overwhelmed with these feelings. If a hospitalization were poorly handled in childhood (as it was with Michael), a subsequent hospitalization will arouse all of the feelings of insecurity and helplessness which accompanied the first hospitalization.

In contrast to children, adults are better prepared to express their resentment of separation. Normally, an adult can talk about his feelings if he is consciously aware of this problem, whereas a child would have to use less mature symbols. Confinement for an adult is usually not as frustrating as it is for a child because an adult's energy is channeled and he is able to release emotion and energy through speech. Then, too, an adult is better prepared to cope with reality and to delay immediate satisfactions and pleasure in view of greater benefits. However, there are adults who find this very difficult. They are often resistive to social demands and controls (hospital regulations, et cetera).

The adult patient who is married usually suffers from marital rather than from maternal separation. If he is secure in marriage he will experience loneliness. If he is unhappy in his marriage and with his family responsibilities, he will feel a certain relief. If he is insecure in marriage, particularly in the love of his partner, hospitalization will cause him to worry excessively about his home. These problems are naturally intensified by prolonged hospitalization.

What does hospitalization mean to an adult patient? It may mean separation from loved ones, inability to continue with one's adult responsibilities in society, great economic loss, temporary loss of self-sufficiency. Depending upon one's previous associations with hospitals or attitudes acquired in childhood, it may signify death, birth, grief, hopelessness. These are only a few possibilities. The important thing to realize is that being hospitalized may mean something different for each patient.

Recently, I was on one of the nursing stations with a student who was to have an experience admitting a patient. The patient was a middle-aged Catholic woman, mother of three children who was to have a breast biopsy the following morning. When she was brought from the admission office, I stepped out of the nurses' station to receive her. I, of course, wanted to demonstrate to the student that the nurse should be warm and cordial in welcoming a patient so I said in the most gracious manner possible, "How do you do, Mrs. Brown. Welcome to St. Joseph's Hospital!" To which she responded with much feeling, "I can't think of any place I would rather *not* be. I just *hate* this place!" When we arrived at her room she looked at her husband and said, "Well, thank God, it is not one of the same rooms anyway!" She was one of the most tense and anxious women I have ever seen and I felt overwhelmed by the extremely strong feelings which she was directing at me, for at that moment I was personifying St. Joseph's Hospital. I asked what it was that she did not like about St. Joseph's. Then she told me that her mother died there of breast cancer and that her mother's two sisters had also died there of breast cancer. What St. Joseph's Hospital meant to her was apparent. Add to that the fact that the patient also had a breast tumor and her tenseness and anxiety became readily understandable.

New relationship problems arise for the hos-

pitalized adult. Later we will more adequately consider the nurse-patient relationship but here we will only allude to it for it is one of the central relationships within a hospital structure. Its dependency nature often results in a transference relationship; the patient transfers the feelings he had for his mother or mother figure, with whom he had his first dependency relationship, to his nurse. The nature of this transferred relationship will be dependent upon the nature of the original dependency relationship.

Another aspect of this relationship problem which may be disturbing for an adult is the change from caring for others to being cared for by others —the change from a role of activity to one of passivity. The staff in a hospital caring only for ill persons does not have the same indulgent attitude towards a sick person as do his family and friends. At home he is unique because of his illness but in the hospital he is one of many sick persons, and this difference in attitude toward him may constitute part of a relationship problem.

Regressive patterns of behavior which may be overtly discerned are numerous when one contrasts the behavior of any hospitalized person during his sickness with his normal healthy behavior. This is true because independence and self-sufficiency accompany the notion of maturity, whereas sickness naturally excludes these two notions and demands dependency and reliance on others.

Now let us turn to a few brief considerations of the effect of pain and bodily illness on an adult. We pointed out before that an infant has a low tolerance of tension and anxiety (pain) and that it has a diffuse reaction which is principally physiologic. Adults normally are able to tolerate tension or pain over a prolonged period of time and their reaction is channeled into certain bodily centers.

It might be well here to attempt to make a few distinctions. Fear is a reaction that is proportionate to an apparent danger, whereas anxiety is a reaction that is disproportionate to a hidden and subjective danger or even an imaginary one.[7] It is normal for a person to fear bodily pain and disease, but this must be in proportion to the cause. When an abnormal response arises one can be sure that anxiety is intermingled with the fear. (It is important not to confuse the precipitating event, if it be a sudden one, with the cause, as in the case of postpartum psychosis. Moreover, at this level of anxiety-reaction one is dealing with a psychoneurotic disorder rather than with a normal response.) A certain amount of anxiety is also normal because all persons have some unconscious motivations and suffer from nameless fears. When the cause of dread or anxiety is unconscious, it cannot be handled at a conscious level because the cause is not known. The physiologic response to fear prepares a person for fight or flight and results in an outpouring of adrenalin, and in an increased blood sugar. These same responses appear with anxiety but the person does not know what to fight, what to flee from, or even where to flee. He senses only his desire to run from, or protect himself from, his dreadful anxiety.

Now, the point to be grasped is that fear and anxiety increase muscular tension and distress in a person already suffering from a physical illness. The picture becomes complex and circular when, in addition to the thing feared, consciously or unconsciously, the very effects or response of fear and anxiety are also feared.

This brings us quite naturally into our next notion of the psychic significance of pain. We noted previously that the biologic meaning of pain is the same for all persons but that the psychic factors involved contribute toward the pain threshold. An understanding of this second component is necessary if we are to realize that pain, while it is an expression of distress and an asking for help, is not necessarily a symptom of mere bodily discomfort. Pain is a kind of communication of the whole person of man, body and mind; when made known to others, it becomes a plea for help. Szaz claims that the repeated complaint of pain is also a disguised aggression against the frustrating, rejecting authority which does not answer the person's plea for relief.

Pain is a subjective experience and is real only to the individual sufferer. The threshold level of pain, or attitude towards pain, reveals much about an individual person and can best be understood in view of the entire ego.

It should be pointed out that pain represents a dislocation of the ego-body relationship in a way similar to anxiety's representation of the disruption between the ego and the external world. Since pain and anxiety have a reciprocal influence on each other, one may be tremendously influenced by the other and anxiety may even be transformed into pain.

The two general effects of illness noted by Anna Freud in children are also observable in adults. The reaction to illness may be one of withdrawal in which the person loses interest in everything outside of himself and wishes to be left alone, or one of exteriorization in which the person demands attention and consideration of others and fears being left to himself. The recuperative phase is characterized by a general irritability in which the person is returning to a normal physical and emotional state. Adults may have more control over these feelings so that irritability may not be so apparent but, nonetheless, adults pass through this phase too.

The emotional life of an individual changes during physical illness. This is due to the changed attitudes in those about him, employer, wife or husband, or children. In general, a person is accepted during sickness for the person that he *is* rather than for what he *does*. The emotional state of sickness is generally one of receptivity and passivity rather than one of activity.

The experience of being nursed, which is usually characterized by passivity and dependence, also produces changes in one's emotional life. The more mature the person and secure in his adult state, the more he is capable of accepting temporarily this state of dependency. The less secure a person is, the more his ego is threatened by a dependency relationship comparable either to infancy or childhood. It has been said however, that even a "normal adult who is nursed through a severe illness cannot at the same time not feel that he is exposed to a series of indignities."[1] Being nursed implies a renouncing of ownership over one's body and a passive submitting of it into the hands of others. Other persons then assume responsibility for the body's most fundamental needs of cleanliness, clothing, urination, defecation; it will be fed by another, moved by another—in short, all that is most intimate to the care of one's personal body must be turned over to others. It is also worth noting that in sickness there is often complete or partial disregard of one's personal preferences, and the patient is subjected to orders, routines, and therapeutic measures.

In the preceding sections we have attempted to explore the psychological significance of hospitalization, physical illness and pain as it applies to both children and adults. This we realize was a very ambitious undertaking but it was felt that greater penetration into the problems of the adult could be achieved by first considering the child's response to the same problems.

Implications for Nursing

It seems quite obvious that these aspects of hospitalization and illness have many implications for nursing and the nursing profession. Although many applications could be made, I would like to suggest two which seem especially pertinent today.

Within the field of medicine attention is being focused on mental health. The National Institute of Mental Health is making grants available to selected schools of medicine and nursing for improvement in teaching psychiatric and mental health principles. The federal government supports such a program because it feels it is of the utmost importance and because psychiatric and mental health principles have admittedly been deficient in medical and nursing education in the past. These grants provide for greater emphasis on human relations content throughout the basic nursing curriculum and a greater understanding of the person who is ill and hospitalized. This simply means that a nurse is being prepared to give comprehensive care to patients; that she should be aware of social and emotional needs as well as of the physical and spiritual ones. This calls for the application of some basic principles. The following are only a few examples:

All behavior has meaning.—Consider the patient who always has his light on. He is communicating something to the nursing personnel and if they do not understand his behavior they will most certainly become impatient and intolerant.

All individual persons are different.—Some are naturally extroverts and others introverts; some are going to express their feelings and needs in a mature way, others will act them out in a less mature fashion. This calls for the application of still another principle.

Accepting a person as he is.—Let a patient be the person that he is and begin working with him at that level.

The hospital is an anxiety-producing situation.—Perhaps this principle is redundant here, but

if it is accepted, then the patient will be properly oriented to the physical surroundings, to the routine, and to what is going to happen to him. He ought even to be permitted to ask questions! These may seem like insignificant things but whether or not they are done means much to the patient.

The last implication for nursing has still to do with the nurse-patient relationship. There is a trend for patient care in hospitals to become very specialized. Many persons are applauding ideas like "progressive nursing care." I think this plan needs to be evaluated carefully and we should be made cognizant of its inherent dangers. Progressive care means that nursing units are set up according to the amount of nursing care a patient needs, but the only need considered, as far as I can determine, is the physical one. For example: A patient is going to have a gastric resection. The first unit that he is admitted to is the self-care unit where he has his work-up done prior to surgery. After this, he is sent to a second station which gives him his immediate pre-surgical preparation and then sends him to the operating room. After passing through the post-anesthesia recovery room he arrives at a third station where he receives intensive nursing care for several days. When the most critical postoperative phase has passed, he is sent to a fourth unit where he receives what is termed "intermediate" care. Finally, he is sent to a fifth nursing station, another self-care unit, for several days prior to his discharge.

Do you have a feeling from this description that we have just passed a car through an assembly line, that some indescribable and unknown object, called a human person, has just been moved from station to station to have a repair job done? What is wanting in such a situation? I have no doubt that such an organization of nursing units would be efficient and give excellent technical care to meet the physical needs of patients. But, the thing that is completely absent is any continuity of human relationships with hospital personnel. Under such an arrangement, the hospital takes on the appearance of the assembly line. If a man were merely an object, a thing, there would be no objection to passing "it" along so that "it" could be worked on, but because of the very nature of a man as a person, as a social being, "he" cannot be handled as an "it."

Perhaps this point needs emphasizing in our time. Because of the mechanized and technical world in which we live it seems extremely important that we put the person back into the right perspective. We live in an era that would often make us think that man is merely a consumer of producers' goods. The advertising industry would have us believe man is made to buy cars and TV sets; that it is not man that matters but the things man has made. Another related exaggeration of our times is what Dietrich Von Hildebrand calls "efficiency"—an efficiency which sacrifices all human warmth and personal involvement to the goddess of production and of schedules.[8] In such a kingdom all things and all persons must move according to schedule. Nursing has not escaped these influences. Wherever a nurse is simply concerned with "room 322" or with "the gall bladder" of Dr. Smith's, instead of with "Mr. Brown" —the thirty-three-year-old father of four children, who has a diseased gall bladder and is in room 322 —she is a victim of the depersonalization influences which are so characteristic of our era. It seems to me, that in our hospitals particularly, we must plan a counter-attack if the personal element is to be "preserved," or more precisely, "restored."

A CHOLESTEROL-LOWERING EXTRACT OF BRAIN

The cholesterol-lowering effect of an orally administered preparation extracted from brain, previously reported in animals and humans, has recently received a broad scale clinical trial at the University of Chicago Clinics.* Of seventy patients originally started on an emulsified form of the material, fifty cooperated in taking this emulsion for a period of at least three months. The serum cholesterol level during this three-month period was compared with that during a control period of comparable duration and encompassing several analyses in the same patient.

Statistical analysis of the difference between treatment and control levels was made in each individual case because of fluctuations in serum cholesterol sometimes correlated with an upper respiratory infection, emotional disturbance or other intercurrent illness. In the fifty patients reported upon, all but five had a fall in the mean serum cholesterol level with treatment and in twenty-seven the fall was statistically significant. In analyzing the data, it was found that the reduction in serum cholesterol effected by this agent showed a direct correlation with: (a) the initial height of the serum cholesterol prior to treatment and (b) the average daily dose of active material ingested. Nine patients with serum cholesterol levels over 250 mgm. per cent who took more than 25 gm. per day of active material showed a mean fall of 60 mgm. per cent (20 per cent) in cholesterol level. Patients who had previously been on a low fat diet showed a further reduction in serum cholesterol during the period of treatment with this material.

In six patients a period of treatment with the extract was compared with a period of treatment on beta-sitosterol (Cytellin) in approximately the same dosage of active material. The reduction in mean serum cholesterol level was quite comparable with these two agents. It is apparent that sitosterol and this brain extract will work more dramatically in patients who have an elevated serum cholesterol; in fact, will have no significant effect when the cholesterol level is normal. This is perhaps because the mode of action of this extract, like that of sitosterol, is based upon an interference with cholesterol absorption in the intestinal tract. Although about 40 per cent of these subjects complained of mild gastrointestinal disturbances, these did not necessitate discontinuing the emulsion in any patient who took it for more than one week. In two duodenal ulcer patients, however, symptoms were apparently aggravated by the ingestion of this agent.

The authors recognize that there is yet no proof that a modest reduction in serum cholesterol would definitely improve prognosis in coronary artery disease though indications are strong that such an accomplishment would serve this end. While serum cholesterol reduction can certainly be accomplished by a dietary restriction of fat, the superimposition of this agent could reduce the levels further. Whether a more severe dietary restriction or administration of this material, or some similar agent, will be more feasible for the long run is as yet an unsettled question. Either approach may be effective in properly selected individuals, but it is a frequent observation that patients on a dietary regimen of any severity tend to drift away from it in time, while they are much more likely to continue to perform a positive act, such as taking medicine, for prolonged periods. The difficulty remains that the benefit to be derived from any given extent of cholesterol reductions is impossible to assess in the individual patient, who will note, at best, no improvement in symptomatology due to atherosclerosis. In view of the unpredictable gain to the patient, the cost in time, effort and money is hard to justify except, perhaps, in those patients who present a frank hypercholesteremia (of greater than 300 mgm. per cent) where we do have reason to relate the coronary disease to the serum cholesterol level.

THE FUNCTIONS OF A REFERENCE LIBRARY—I

I once read a little verse which begins—

"There are books to divert,
There are books to instruct,
There are books to excite, to arrest, to inspire. . ."

Books in all these categories will be found in any reference library, for libraries serve people, people with dissimilar interests, knowledge, and sensibilities, and must differ as people do; but usually the books and other publications in a reference library are those which can be used in some way to instruct, to answer questions. The reference library is a sort of information bank, a place in which information is deposited and organized, and then retrieved and dispensed when requested. It can cover the whole range of human knowledge and thought, as in the case of the Reference Department of the New York Public Library; or, at the other extreme, it can be limited to one subject such as art or labor relations. Even those with such subject limitations usually provide materials for research in their own specialty plus general information on other related subjects.

When we select the information to be included in a library we are defining the areas of knowledge in which it will have the greatest strength. If we are organizing a medical reference library we shall endeavor to discover what is being published in the fields of medicine that is reliable and accurate, and which medical men and women would find useful in some way. At this point compromises begin, as they always begin, with money. Usually there won't be enough money to buy all the publications which might be useful, and not enough employees to do all the necessary cataloguing and indexing, even if all such books, magazines, research bulletins, government documents, theses and miscellaneous pamphlets could be bought; even in the one broad area of medical knowledge.

We haven't mentioned the foreign language problem. Are we to collect all the Spanish, French, German, Italian, Danish, Dutch, Belgian, Norwegian, Russian, Swedish and Swiss publications that seem important? Medicine knows no language boundaries. Neither do education, engineering, metallurgy, geology, economics, chemistry, and physics; and such a list could be made quite long.

It was mentioned that only reliable and accurate publications would be selected for the library, implying the use of qualitative standards to evaluate unseen objects. Whose standards?

We have no specifications describing desirable weight, purity, fineness, moisture content, or anything else that can be measured. Selection must be a matter of judgment based upon knowledge, experience and personal values.

In a reference library a book should seldom stand alone, for books overlap each other, both in time and in subject matter. An important job of the librarian is to select those books which supplement one another in original form, those which form the basic literature as opposed to those which merely derive from that literature. Periodicals and documents must be used to supplement what can be found in the latest books.

Verification is an important function of a reference library to which the average person seldom gives thought. Errors are as ubiquitous in the library as elsewhere. The story is told that the famous "Boss" Kettering wanted a sign placed over the doorway to the library at the new General Motors Research Center. It was to read, "Beware, All Ye Who Enter Here."

How often the librarian reads in book reviews such statements as, "This is truly an outstanding book, however, on page . . . the author has made quite a serious error. . ." In another review, there will be a similar statement, and an error on another page will be noted. Yet, assuming that this book is important, it must be in the library. The librarian cannot mark such errors. He would not find all of them, and perhaps the reviewer is wrong. Obviously, also, if a book has been based on extensive research, and carefully written, it may be quite out of date by the time it is published, depending upon the state of research in that field of knowledge at that time. Such books must be purchased and become reference sources. The errors they contain may be not only preserved but disseminated.

If a person seeks information on a subject, borrows a book, and takes it home and reads it, he may believe that he is quite an authority on the subject. On the other hand, if he goes to a reference library and asks for information on that subject, he may be given many books and many periodicals to supplement the books. Almost invariably a different picture will develop in the reader's mind. He will be aware of differences of opinion, statements that seemed factual will now

seem dubious, and his feeling of confidence in his knowledge will have been tempered. He may feel less satisfied but he will be better informed.

SOCIAL SERVICE

Community Agency Participation in Medical Care

The citizens of Minnesota traditionally have exhibited a fine sense of social responsibility for people in need. This is a part of our pioneer heritage within our memory. Citizens in various communities throughout the state were concerned about people who needed medical care long before there were many organizations or agencies. The old medical charts contain letters from ministers, judges, county commissions, public officials and friends. Some of you will recall instances where local communities were greatly concerned about medical care for some patients.

The original reason for having legislation passed to make the county commissioner responsible for signing University Hospital papers was a wise one, as the county commissioner knew the people in his district. In those days the county commissioner often accepted responsibilities for helping patients when the hospital care was completed. He would ask the assistance of the people in his district to do many of the services now provided by agencies and organizations.

The Minnesota Children's Code passed in 1917 provided for Child Welfare Boards in each county. Yellow Medicine County was the first and within a short period of time most of the counties of the state had established such boards. They were made up of five citizens whose duties were to provide protective services for children. The social service department of the hospitals worked closely with these boards. In those days it was difficult for the department to locate community resources and there were instances where the social workers contacted as many as forty groups to complete the services the patient needed.

The passage of the Social Security Act in 1937 provided for a county welfare board in each county. Responsibility for major services to people of the community was delegated to a paid professional staff. These excellent agencies in every one of the eighty-seven counties give generously of their time and services to assist in carrying out the hospital staff's plan for patients.

For this year's discussion, we are presenting a patient situation illustrating the way in which community agencies and organizations participate in assisting the medical staff in its plans for patients.

ANNIE LAURIE BAKER

Community Participation in County and Township

Donald Matson is one of approximately 1,400 people who are receiving assistance or service from the Todd County Welfare Board. Being one of 1,400 would give the impression that it would be impossible for an agency with a staff of six professional workers to concentrate its efforts toward completely beneficial services for any given client. Quite to the contrary it has been the experience of the agency that it can give services and stimulate community action toward a goal.

Donald Matson, as one of 1,400, had no less rights or no greater rights than any other person of the 1,400. He was an individual who was younger than many others of the 1,400; he was an individual with a medical problem that could not be healed or cured as such; however, he was an individual who could be helped if things could begin to happen and people and organizations began to do things. Who were the people, the organizations, and what were the things? To state it simply, Donald was injured, severely injured. He was hospitalized and after a while he began to convalesce. The local hospital and his physician had done their part and it was Donald's physician who suggested the referral to the University of Minnesota Hospitals. He suggested this to Donald's parents and told them to contact the County Welfare Agency. At this point Donald became one of the 1,400; people and organizations began to do things.

Before proceeding with the case history, let us look at the Todd County Welfare Agency and its Board. The professional staff is six in number and it gives service to 1,400 people. The agency is the only organized social agency in the county. It has the administrative function of providing financial assistance to the aged, to dependent children, to the needy blind and to the disabled, and to persons in need of medical services at the University Hospitals. It has the responsibility to provide case work services to all clients receiving financial assistance and to provide these services either upon request or on its own initiative to people not re-

ceiving financial help with particular regard for minor children. Upon assignment, the social worker works directly with the client and his family under the direction of the supervisor and executive secretary who is, in turn, responsible to the county welfare board. I do not wish to portray the Todd County Welfare Board as typical or atypical. Its seven members meet twice monthly with the executive secretary on welfare board matters. Of the seven, five are county commissioners, who are elected officers in the county government. In Todd County, three of the county commissioners have full time farming operations, one is engaged in public relations work for a state-wide organization, and the other is a foreman of a construction crew. Two of the members are appointed by the Commissioner of Public Welfare. One is a farm housewife and the other a retired railroad conductor. The average tenure of the elected officers is about ten years and of the appointed members about six years. The welfare board is concerned not only with services to clients, but because it is an administrative board, it must be aware of the cost of these services and the probable benefits derived from the expenditure of the money. This board, non-professional, is the group that must act on the recommendations made by the staff.

At the time the request for assistance was made, what type of family had asked the help of the agency? Donald's father was fifty-eight, his mother forty-one. Donald was seventeen, a sophomore in high school. He had a twin brother and three other siblings ranging in age from eight to thirteen. The family had a low income, and the home conditions were none too good. Donald's father appeared to be a coarse individual with a "chip-on-his-shoulder" attitude. Donald's mother displayed an attitude of self-pity. At the time the social worker first talked to the family, the parents saw the University Hospitals as an extension of local hospitalization. There was no indication that the parents had any thought of their son's being able to help himself in the future. Donald's mother talked of her "poor son" who would never be able to care for himself. Without motivation from his family, who would be able to help Donald?

Upon referral, the county agency sought help and discussed with other public officials the use of other possible resources. The County Public Health Nurse, along with the County Welfare Board staff, felt that Donald might be rehabilitated. The Veterans Service officer (Donald's father was a veteran) was asked about the use of resources within his department. The use of the Mayo Clinic with the resources offered by the American Legion Child Welfare Fund was discarded because of the delay likely to be encountered. In conference with the local physician, the use of Gillette State Hospital was also discarded because of the lack of specialized services. The first ray of hope came after a referral to the Social Services Department of the University Hospitals. The agency was advised of the soon-to-be opened Department of Rehabilitation. A conference was held with the local physician who said Donald could return to his home to await admission to the Department of Rehabilitation. The agency arranged with a community organization, the American Legion Auxiliary, for the use of a wheel chair. At this point the second major community organization, The Village Council, was brought into the planning. The plan of rehabilitation had to be presented to this group's executive officer, the Village Recorder (who, incidentally, doubles as the Chief of Police). He was dubious but willing to listen. He questioned whether Donald would be able to live with his family after he had been rehabilitated. This first contact was inconclusive.

After Donald had been home for a week, he was returned to the local hospital. In the week that he was home, he was not removed from the wheel chair. His parents were afraid that they would hurt him and, as his mother explained, "anyway, we had no bed for him." Upon return to the local hospital, Donald was extremely discouraged and called the hospital a "prison." He wanted to go home, but he seemed to realize that it was "up to his mother" as to whether he could return home. Donald reached this low point a month after his referral to the welfare agency, but we must remember that he had been in the hospital for four months with the exception of one discouraging week at home. It was at this low point that the agency began to explain to Donald that they could arrange for him to be admitted to the Department of Rehabilitation. Because no admission date had been set, the agency had to proceed slowly to develop a motivation in Donald. They explained, too, the financial aid program, Aid to the Disabled, and how it could be a resource to Donald.

With this, planning moved ahead. The Village Recorder, apparently encouraged by the attitude Donald now held, said that the Village Council

would underwrite certain expenses if rehabilitation could be achieved and if the Aid to the Disabled program could be used as a resource after the period of rehabilitation. The agency began a planning phase that took into consideration Donald's return to the community. The County Public Health Nurse assured the agency that she was available to the parents on a consultative basis, which did much to help Donald's parents to understand that his injuries need not be totally disabling. The local school authorities said that they could plan a program for Donald and gave assurance of arrangements for physical care, if needed, when Donald was in school. The possibility of foster home care was touched on only briefly because of the parents' changing and improving attitude. This growth of motivation from Donald's parents continued. Just before his admission to the Department of Rehabilitation two months after the initial referral, the parents were hopeful that Donald would learn to walk again and that "he would stay (at the Department of Rehabilitation) if any good could be done." This attitude was a great change from the time when Donald's mother could speak only of her "poor son."

One of the first rehabilitation measures was the procurement of leg braces for Donald. The agency was requested by the Social Services Department to provide authorization for these appliances. To the agency, this meant its first request for financial assistance from the Village Council. The Village Recorder expressed doubt concerning approval from the Village Council because it had been asked to pay a bill for care at the local hospital for Donald. Donald's parents were hesitant about making a request for asistance from the village, and it became necessary for the local agency to go to the Matson home and assist in the completion of the request for assistance. Because of the expression of doubt on the part of the village recorder, several village council members were personally contacted. One of these members suggested that a house-to-house canvass for funds for the braces be made or that some community group be asked to pay for the braces. The agency naturally discouraged this because "this would not take care of a long range plan for Donald which is what we wanted at this time." The agency suggested that the council hold an immediate emergency meeting. This was held, and approval was given for purchase of the braces. This approval was given on condition that the agency worker appear before the village council to fully explain the proposed rehabilitation program. The village council was made aware of the actual economy of rehabilitation, which, if successful, would mean self-support or partial self-support. The community became aware of rehabilitation possibilities through the activity of the agency and the village council, and two service organizations—the American Legion and VFW held a benefit dance to raise a fund to be used when Donald returned to the community.

Planning for return continued; a local printing house showed a willingness to accept Donald for employment if he were properly trained, and the possibility of a study program at the local high school was again planned. These plans did not materialize, and Donald was placed for employment in Minneapolis.

An Aid to the Disabled grant was approved by the Todd County Welfare Board to supplement his earnings and the Hennepin County Welfare Board was asked to supervise Donald and prepare a monthly budget for him. The grant was based on need which includes all maintenance costs plus transportation to and from work. Because the latter cost fluctuated from month to month, it was necessary that the grant be changed in accordance.

At present, three agencies are working with Donald; The Todd County Welfare Board which provides the supplemental aid, the Hennepin County Welfare Board which makes the budget recommendation to the Todd County Welfare Board and the Social Services Department of the University Hospitals, which has the medical supervision of the case.

From the initiation of the case in July, 1954, to December, 1956, the total amount expended by the agency, the village council and the fund was $5,408.00. Of this total, University Hospitals costs were $3,469, and Aid to the Disabled grants were $606, the village spent $1,110 and the fund obtained by the benefit dance provided $223.

In order to assist Donald to obtain the medical care and rehabilitation he needed, eighteen social agencies in Todd County were involved, and ten agencies participated in the plans worked out by the local physician and the Todd County Welfare Board.

ANTHONY M. CREMERS

INFANT FEEDING—PROTEIN FACTOR

The normal full-term baby in the early months of life should have from 2 to 4 g. of high grade protein per kg. of body weight per day. If any official agency could define the requirement more precisely, it should be the Committee on Recommended Dietary Allowances operating under the Food and Nutrition Board of the National Research Council. In its official publication—National Research Council Publication 302, "Recommended Dietary Allowances" (1953), the Committee discusses the subject at length and reaches the conclusion that more convincing evidence is needed, before a specific recommendation can be made as to infant protein requirements or optimal allowances.

The Committee finds that breast-fed babies may receive as little as 2 g. protein per kg. per day, and that that may be sufficient. It also believes that in formula feeding, a level of 3.5 g. protein per kg. per day should better be prescribed.

The main difficulty in arriving at a conclusion as to what specific level of dietary protein is best for the baby lies in the fact that criteria for optimum growth and health have not been agreed upon. Babies receiving 3.5 to 4 g./kg./day of protein in a digestible form of cow's milk are found to retain more nitrogen, and to produce protein-containing tissue at a greater rate than their contemporaries fed human milk with its lower protein levels. Yet there are those who are reluctant to accept this as valid evidence of superiority in higher protein-level feeding. So, the search is on for other criteria of optimal infant health and progress that may possibly demonstrate that feeding protein at the lower levels found in human milk may produce better human beings in the long run.

Biological Values

The protein composite of cow's milk is higher in the casein fraction and lower in the "whey proteins"—lactalbumin and lactoglobulin—than human milk. This fact is no longer considered to be of importance in feeding the human baby. Differences in biological value of the protein composites show up only in feeding fur-bearing animals.

"Recommended Dietary Allowances" (NRC Publication No. 302) states, "The limited evidence available indicates that with improved processing techniques for increasing digestibility, the utilization of proteins from cow's milk is similar to that of the proteins from breast milk."

In Terms of Amino Acids

It is the amino acid moieties of the protein molecule that are of specific nutritional importance. Work is being done in at least two clinics to determine the minimum infant requirements for the essential amino acids. From measurements so far made, it appears here again that human milk carrying two to 2.5 g. protein/kg./day supplies no more than marginal amounts of certain of these amino acids, while the cow's-milk formula provides more nearly optimum amounts.

Protein Calories

There is another way in which the protein factor in infant feeding is often quantitated. In average human milk, protein calories represent less than 9 per cent of the total calories. The usual formula prepared from cow's milk with carbohydrate modification contains well over 15 per cent of total calories in the form of protein. Much that is known about the growth and composition of the human body and its various organs and tissues would suggest that the dietary patterns during the growing period should be more in the range of the latter than the former. Levels of dietary protein higher than that found in human milk have been shown to produce better growth in rats.

Some research projects are now on the planning board which may give us the answer to this rather puzzling question: Is the baby better off with the relatively lower protein intake supplied by breast feeding? Or, did nature make a mistake in failing to give modern mothers the ability to secrete a milk of higher protein content? Or, as the question was recently phrased by one of the principal investigators in the field of nitrogen balance, Dr. Stearns, "It leaves one wondering why the young infant has a capacity to utilize protein in amounts far beyond that which he could possibly obtain from his natural food."

Too Much Protein (?)

On the other end of the scale, the question is raised from time to time, as to whether it may be harmful to the baby to feed him protein at a level higher than that contained in human milk. The possibility of overloading his excretory capacity is argued. Some indications of a negative answer to this question are recounted above. There are others.

In recent years, there are an increasing number of proponents of infant feeding with cow's milk without the usual addition of carbohydrate. Such

satisfactory results have been observed that the non-carbohydrate feeding practice has been established as routine in many hospitals. And there are thousands of babies that have been so fed successfully. Such a formula gives a baby protein at the rate of 5 to 5.5 g. protein/kg./day. And here the protein calories represent fully 26 per cent of total calories. One must conclude that if the normal baby finds any difficulty in managing the higher level of protein in the cow's milk formula, such should be exhibited in non-carbohydrate feeding.

("Solute load," to a lesser extent from protein in the formula, more important possibly from the point of view of the higher electrolyte content of cow's milk, is also the subject of investigation in a number of clinical research centers. It also was the subject recently of a report from the Nutrition Committee of the Academy of Pediatrics.)

Protein Curd Tension

The behavior of the protein of cow's milk with respect to curd formation was long of concern in infant feeding. Medical literature these days hardly mentions the subject. As suggested in the NRC publication quoted above, and as has been stated many times in the literature of the past thirty years, the processing through which raw cow's milk passes in the preparation of evaporated milk has so altered the character of the casein fraction that it does not coagulate in a cheese-like mass in the infant stomach as does unheated cow's milk. The curd tension compares favorably with that of human milk.

Acidification of milk formulas originally had as one of its bases that of flocculating the curd before it enters the baby's gastrointestinal compartment. The increase in formula feeding with evaporated milk is one of the factors that has lessened interest in acidification. (Another argument for acidified formulas—that of safety in homes not provided with refrigeration—is still important in certain areas.)

Infant Disorders: Allergy

The involvements of protein in the feeding of other than normal babies cannot be treated in this short discussion. Our growing interest in world conditions has caused our U. S. medical and nutritional literature to be well preoccupied with reports on Kwashiorkor, prevalent in the technically underdeveloped countries, protein deficiency being a definite etiological factor. Attention being focused on mentally retarded children has directed attention to a congenital defect in metabolism, variously estimated at two to six per 100,000 births, which involves a disability properly to metabolize the amino acid, phenylalanine. The cereal protein, gliadin, is a metabolic stumbling block for some babies. A disturbance in protein anabolism is a causative factor in failure to produce gamma globulin. The importance of adequate protein levels in feeding prematures could be the subject of a review in itself.

There is one clinical manifestation, however, that should be discussed since it continues to be the subject currently of numerous reports in the medical literature. That is food allergy as it relates to milk protein.

Wide differences of opinion are being expressed as to the prevalence of milk protein allergy and its spectrum of symptoms. As many as fourteen behavior patterns have been listed as being caused by milk allergy, including general baby unhappiness! However, the proportion of the infant population definitely allergic to cow's-milk protein is reliably estimated as no more than 1 per cent.

The more soluble proteins of milk, lactalbumin and lactoglobulin, are the most likely culprits. Fortunately, they can be rendered relatively nonallergenic by heat, such as that to which milk is exposed in the production of evaporated milk. Allergenicity due to the casein fraction is less often observed. Unfortunately, exposure to heat does not effect denaturation of casein. In general, it is only in the small proportion of cases where the baby is intolerant to cow's milk casein that it is necessary to resort to synthetic milks made from meat or vegetable products, or from hydrolyzed proteins.

The high nutritive value of cow's milk in its various aspects would point to the importance of keeping the period of milk-free nutrition as short as possible, if and when withdrawal of milk is positively indicated. In this connection, Dr. Breslow recently offered the following diagnostic precaution: "Favorable results from the substitution of other products for cow's milk in the infant formula should not always be interpreted as indicating an allergy to milk protein."

Conclusion

From the evidence available at this time, one may conclude that modernly constructed feeding formulas prepared from evaporated milk provide

the normal baby with protein at desirable levels of intake, and of physical character appropriate to the infant's digestive capacity. The level is generous compared with that provided by average human milk. The conclusion is supportable that a generous allowance of protein in formula feeding provides a margin of safety that is compatible with good growth and maintenance of cellular tissue, and that it makes possible an accumulation of reasonable protein reserves which helps to provide adequate defenses against illness. There is no direct evidence that such a formula is too high in protein.

Whenever dietary allowances are considered, one must keep in mind that each individual inherits a characteristic metabolic pattern just as he inherits different patterns of body shape, size and coloring. Previous stresses to which the child has been exposed may cause variations in protein requirements. To the extent that the baby varies from the average, and particularly where the individual suffers a serious abnormality, metabolic or otherwise, competent medical management is clearly indicated.

THE MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

STUDENT POSING AS DOCTOR GIVEN NINETY-DAY TERM IN ST. PAUL WORKHOUSE

On March 26, 1959 David L. Thompson, twenty-five, 847 Twenty-Fourth Ave. S.E., Minneapolis, a graduate student studying Industrial Relations Psychology at the University of Minnesota, was sentenced by the Hon. J. Jerome Plunkett, Judge of St. Paul Municipal Court, to serve a term of ninety days in the St. Paul Workhouse for the crime of assault in the third degree. On February 20, 1959, the defendant had entered a plea of guilty to the charge, which was placed against him after an investigation by officers of the St. Paul Police Department and a representative of the Minnesota State Board of Medical Examiners revealed that Thompson had been examining young women at a downtown St. Paul hotel under the guise of making pre-employment examinations for an Arizona corporation.

After receiving a telephone call on January 27, 1959, from the husband of one of the three women examined by Thompson, who had signed the hotel register as "Dr. Sperman" from Phoenix, Arizona, the investigators learned that during the preceding three days the defendant had called a number of women by picking names at random out of the St. Paul Telephone Directory. Thompson told these women that he was a representative of the Scandia Corporation of Phoenix and if they were out of work and wished to secure employment with the Scandia Corporation, it would be necessary for them to have a physical examination, inasmuch as this corporation was engaged in a business involving exposure to radiation by its employes. He added that the corporation was in the process of setting up a plant in St. Paul for the manufacture of x-ray equipment and therefore it was recruiting employes to staff the plant. When Thompson was arrested at the hotel, a number of medical instruments were found in his room including a stethoscope, speculum, opthalmoscope and a thermometer. He also had in his possession a deep-fryer, which he was using to sterilize the instruments, a pair of rubber gloves, test slides and a tube of lubricating jelly.

In a written statement given by Thompson, he claimed he was engaged in these activities in order to "obtain data on surprise reaction and gullibility" for the purpose of writing a thesis on this subject. In further attempting to explain his activities, Thompson stated: "During the interview I asked the girls about their home life, their parents, their interests, their lifetime goals, their activities, their problems and the people with whom they associate. I also misrepresented a questionnaire on medical history, asking them if they had sore throats, colds, painful menstrual periods, bloody or painful urination or bowel movements, headaches, frequent visitations to the doctor, whether they had even been turned down for a job due to physical handicaps or sickness, and whether they were concerned about the possibility of cancer. In attempting to do this, I hoped to gain an index of their reaction-apparent to such a ridiculous scheme. To me, the idea of a company sending a man from Arizona to interview girls and give them a physical exam was preposterous. These girls, in general, submitted to the physical exam and their reactions under such circumstances were noted. Therefore, I had an index of their reactions in a situation which placed them in an embarrassing position, assuming they believed I was qualified to give the examination. I also got an index of their gullibility and intended to attempt to correlate these indexes with the Bell Adjustment Inventory." The third-degree assault charge placed against Thompson was based upon his actual physical contact with the young women in using the various instruments enumerated above.

President's Letter

MORE ABOUT BLUE SHIELD

I hope every doctor in Minnesota reads the Blue Shield story written so very well by Dr. Olaf I. Sohlberg in the February, 1959 issue of MINNESOTA MEDICINE.

As Dr. Sohlberg stated, "There is so much misinformation and lack of information about Blue Shield that a few words might not be amiss. The basic principles are so simple and straightforward that when they are known, usually they are easily accepted and enthusiastically supported." Please read or reread the article.

It was my privilege and pleasure to attend the 1959 Blue Shield Professional Relations Conference held at the Drake Hotel in Chicago early in February. The discussions of professional relations which took place in the physicians groups centered largely around consideration of some of the basic policy factors affecting the establishment and maintenance of good professional relations.

First, the continuing need for effective communications was discussed. It was brought out that there is need to correct some of the widely held misconceptions concerning the Blue Shield program; to define the range of community need the Blue Shield program can be expected to serve; to create understanding of the basic purposes health care should cover; help to meet the socio-economic problems confronting medicine and to keep physicians informed about current developments.

Second, the plans must remain closely allied with their sponsoring medical societies, and liaison groups should be established so that the medical society and the plan may work together in finding solutions to problems of mutual concern.

Third, in the matter of fees, Blue Shield must not place itself in the position of establishing fees for any segment of medicine. This is a matter of medical policy and should be resolved within the state or county medical societies. In all matters involving medical policy and ethics, the sole arbiter must be the medical society.

Fourth, there was a discussion of the problem of overuse and its effect on professional relations—a problem in preserving the fiscal soundness of Blue Shield. It was suggested that in the problem of utilization, plans should approach their solution through appropriate channels of the state or county medical societies. Blue Shield cannot succeed without the wholehearted support of the medical profession.

There was considerable discussion concerning the AMA resolution to promote the financing of the health care of the aged. It was agreed that both the health insurance industry and the prepayment plans can apply their particular resources to the implementation of the resolution. Minnesota Blue Shield and the council of the Minnesota State Medical Association have had several meetings, and it is hoped there will be a plan for presentation to our House of Delegates' meeting in Duluth.

A report published by the Health Information Foundation best illustrates the attitude of the actuarial committee in facing this problem.

"It is interesting to note that, *without a major federal program of health insurance,* there is little difference these days in the volume of medical care received by people in widely separated income groups. Clearly, medical care is generally available to the public regardless of ability to pay." That meant that our American society has accepted the philosophy that no person should be denied necessary health care for financial reasons. We must decide how best to keep our system voluntary.

UNIONIZATION OF HOSPITAL EMPLOYES IN MINNESOTA MAY SET NATIONAL PATTERN

The eyes of the nation are focused upon Minnesota. Apprehensive hospital administrators, vendors of health care plans, as well as the general public are observing organized labor's success in unionizing hospital employes in the Minneapolis-St. Paul area.

In the April 2, 1959, edition of the *Wall Street Journal,* the Minneapolis-St. Paul, San Francisco-Oakland, California, areas were listed as two significant concentrations of organized hospital employes.

Observers are not discounting the possibility of another boost in the already spiraling cost of medical care should the trend continue to grow throughout the country. Because the trend could significantly affect the future cost of medical care, the following article in the *Wall Street Journal* is directed to the attention of all members of the Minnesota State Medical Association:

A drive by labor unions to organize hospital employes is picking up speed in New York City and now threatens to spread across the country.

The campaign, if successful, almost certainly will worsen the already desperate financial plight of the nation's voluntary, non-profit hospitals, many of which are tacking up record operating deficits despite steady increases in room rates and service charges. Broad-scale unionization of hospitals also would tend to boost still further the hospital fees patients pay and the premiums charged by Blue Cross and other health insurance organizations.

"If the unions were to organize us, there wouldn't be a request for a measly 20 to 30 per cent increase in Blue Cross premiums—the premiums would have to be doubled," warns Dr. Henry Pratt, director of Manhattan's massive 1,431-bed New York Hospital, where the muscular International Brotherhood of Teamsters now is attempting to organize the institution's 2,700 non-professional employes.

Three Unions Compete

The Teamsters' organizing campaign in New York is being led by Henry Feinstein, president of Local 237, who earlier this year achieved brief fame when he started a drive, later abandoned, to organize New York's police. However, Mr. Feinstein's union is not alone in this new venture—the Retail Drug Employes Union, Local 1199 (affiliated with the 250,000-member Retail, Wholesale and Department Store Union of the A.F.L.-C.I.O.) and Local 302 of the American Federation of State, County and Municipal Employes, A.F.L.-C.I.O., also are trying to sign up the more than 30,000 non-professional workers in the city's 79 non-profit hospitals.

Meanwhile, in Florida, Teamsters' Local 237 there has launched a drive to organize the non-technical employes of county hospitals in Miami. The immediate targets are Jackson Memorial Hospital, with about 2,500 workers, and Kendall Hospital, with 250. After this campaign, the union will try to organize Miami's private hospitals, according to William Huet, business agent of the local.

As yet, the Teamsters have no nationally coordinated organizing drive on hospitals in the works, states Jimmy Hoffa, president of the union. Instead, he said, each local situation will be studied and if the prospects are favorable for organization, the International will give its approval to the local to go ahead.

Mr. Hoffa says that, although he okayed the New York drive, he has turned down repeated requests to organize Detroit's hospitals on the grounds that the climate of public opinion there is not ready yet. But in time, Mr. Hoffa says, he expects the public attitude in the nation as a whole to grow more favorable to hospital unionization and then, he adds, hospital drives might be undertaken on a broader scale by the Teamsters. Success in organizing New York's hospitals, of course, could well encourage the union to undertake such broader-scale drives.

At Stake: 1.4 Million Workers

At stake in these parallel national organizing efforts is a labor group, now largely unorganized that is bigger than any present national union—the Steelworkers, Auto Workers or even the Teamsters, themselves. There are now more than 1.4 million persons employed by the nation's 6,800 hospitals, according to the American Hospital Association. Of these, 700,000 work in voluntary, non-profit institutions, roughly 450,000 are employed in city, state and county hospitals, and the remainder in Federal institutions and private hospitals that operate for profit.

So far, only in the Minneapolis-St. Paul and San Francisco-Oakland areas is there much of a concentration of unionized hospitals. Significantly, the daily room charges and Blue Cross premiums in both of these localities have now risen far above those in New York City, where only two of the city's 81 voluntary hospitals so far recognize unions as bargaining agents for their employes.

In New York City, meanwhile, the situation is fast coming to a head. Picket lines have been thrown up around some of the hospitals. Workers at five hospitals who have been signed up by Drug Workers Local 1199 have already voted to strike, if they are not granted recognition. Attorneys for the various hospitals, it is admitted privately, already have drawn petitions for anti-strike injunctions to be rushed to court the minute their workers walk out.

"A Matter of Life or Death"

"If they should stop truck deliveries to a hospital, it could become literally a matter of life or death," says one New York hospital director.

Two such incidents already have generated considerable ill will between hospital administrators and the unions and even among the unions themselves. At New York Hospital, ten Teamster truck drivers refused to cross picket lines recently—with the result that surgical instruments, glassware, plumbing fixtures and other hospital supplies went undelivered. At Presbyterian Hospital a truck loaded with oxygen also refused to cross a picket line.

The incidents were publicly deplored by Leon Davis, president of Local 1199 of the Drug Workers, who charged that such Teamster tactics "will play into the hands of hospital managements so they may accuse all unions of being irresponsible."

Teamster Feinstein's comments on the supply tie-ups are hardly reassuring to the hospitals. He says that while he has not ordered any stoppage of deliveries so far, on the ground that there is no strike yet, "truck drivers are free to decide for themselves if they want to cross a Teamsters' picket line."

"Evacuate the Patients"

If the union does call a strike, says Mr. Feinstein, "we'll ask the hospital to evacuate the patients. We don't want to be put in the position of causing anybody's death. The hospital will have sufficient time to take the patients out." Any Teamster strike of hospitals would require the approval of the union's Joint Council in New York and also of the international union, headquartered in Washington.

In the three-cornered race to unionize New York's hospitals, Local 1199 of the Drug Workers seems to be out in front, claiming it has signed up a majority of the workers at twelve hospitals in the city. The other two unions, however, have reached "an informal understanding" and recently the Teamsters even went so far as to send pickets to help out at Presbyterian Hospital where the municipal workers union is concentrating most of its efforts.

Officials of all three unions say their organizing efforts are aimed solely at raising wages of hospital non-professional workers, which they claim are among the lowest in the nation. They charge that pay for orderlies, porters, dietary workers, nurses' aides and other non-professionals ranges roughly between $34 to $40 a week in New York's non-profit hospitals. Workers in the city's municipal hospitals, on the other hand, start off at a minimum of $53 a week.

As charitable, non-profit institutions, the hospitals are exempt from the minimum wage, disability and unemployment insurance laws.

Ascending Deficits

"We don't deny that we pay a low wage," says Joseph Terenzio, the tense, dark-haired young executive director of Knickerbocker Hospital. "We want to pay higher wages but we are paying as much as we can right now." He points to a chart sketching in red ink more than five years of ascending deficits. "What do these unions expect us to do, open up a trap door in the floor and pull out a big bag of money?"

Dr. I. Magelaner, executive director of Jewish Hospital of Brooklyn, says flatly: "Wage increases cannot be given when the money does not exist."

There is no question that many hospital employes (about 80 per cent of them here are Negroes and Puerto Ricans) are disgruntled and in favor of anything that would raise their wages. "I'm barely able to pull along, and only because I get help from my mother," says 21-year-old Alvin Phillips, an orderly at Manhattan's Beth Israel Hospital, who makes $35 a week.

John Carr, a wall washer at Jewish Hospital in Brooklyn, declares angrily, "I'm ready to strike right now, if possible. My take-home pay is $78.99 every two weeks and I have to borrow money from one payday to the next."

Handicapping the union drive is the fact that neither the National Labor Relations Act nor the state labor law requires non-profit hospitals to recognize or bargain with unions. Each hospital is free to follow its own course of action. So far, most of the hospitals have taken the position that they will not deal with the unions in any way.

Fears of Interference

This stand apparently is based on hospital administrators' contentions that the unions, if recognized, would interfere with the care of patients.

"Everyone in a hospital, from the janitor to the head nurse, has one purpose, the care of patients," argues New York Hospital's Dr. Pratt in a calm, patient voice. "We do not want a third party—a union or anyone else without responsibility—to stand between the patient and the people who are charged with his care."

Unions, some other hospital officials speculate, might want to set up hiring halls where union officials could determine who goes to work in a hospital—or unions might want to have a firm say about whether an employe should or should not be fired.

However, the main ground for opposition to the union drive undoubtedly is financial. Hospital leaders in New York like to point to Minneapolis as an example of what might happen if union demands are granted.

Costs per patient per day, at hospitals where Local 113 of the Building Service Employes Union has obtained a contract, are estimated at $38 to $40, compared with the $27 to $35 in New York City. In Minneapolis, orderlies earn $250 a month to start and $266 after two years. Unskilled workmen such as dishwashers earn $235 monthly and $251 after two years. A hospital official in Minneapolis figures this is $60 to $80 a month more than in non-union hospitals in "comparable cities."

Costs of Coverage

The impact is equally pronounced in Blue Cross rates in Minneapolis. An official of Swedish Hospital there reports, "Our Blue Cross full family group contract is around $10 a month, probably the highest for comparable coverage in the nation." In New York, it is $5.34 and roughly comparable plans cost $9 monthly in Denver, $5.75 in Durham, N. C., and $9.55 in Fargo, N. D., according to other hospital officials. (Blue Cross' health coverage is handled by twenty-five different regional member associations; benefits offered by these associations often vary slightly so premium comparisons are not completely indicative of the respective costs of coverage).

Similarly, in the San Francisco-Oakland area about twenty-three hospitals with a work force of 2,900 employes are unionized. The average inpatient cost is slightly over $40 a day per patient, according to W. J. Kramer, executive secretary of the San Francisco Hospital Conference. He says costs have been rising 4 to 5 per cent a year and he expects them to go up another 4 per cent by 1960. However, Mr. Kramer believes the steady wage increases there are not due so much to unionization as to San Francisco's "generally high wage levels." Hospital wages there start at $58.90 a week for the lowest-scaled employes.

Wage levels comparable to these would have an immediate effect on New York's already deficit-ridden hospitals. Last year, for example, New York Hospital had an operating deficit of more than $1 million. Knickerbocker Hospital with operating costs of $2 million a year, went into the red by $156,000.

To get cash to cover the deficits, New York hospitals are having to borrow from the principal of their endowment funds, which generally have no restrictions on their use, in addition to using interest on their endowment funds and soliciting contributions from the public.

They also are pushing hard to get a 20 per cent boost in the amount the local Blue Cross plan pays the New York hospitals. This figure now amounts to $26 a day for a patient with Blue Cross coverage.

Blue Cross itself is running into serious money

troubles. Last year, New York's plan, known officially as the Associated Hospital Service of New York, asked state authorities for a 40 per cent increase in premiums to cover mounting losses. The state, after hearing strong complaints from consumer groups and some labor unions, trimmed the allowable premium increase to 22 per cent. The result, according to Blue Cross officials, was a deficit of more than $20 million in the Association's operations. The Association has indicated it will appeal again to the state for a higher premium very shortly.

Because of the swift spread of Blue Cross in recent years, hospitals have become increasingly dependent upon its payments. "About 40 per cent of our in-patients income is from Blue Cross," says Dr. Pratt of New York Hospital.

Public-Charge Patients

Most non-profit hospitals also are charity institutions, with indigent patients taking up a large share of the beds. In New York, the city pays $16 a day to the hospitals to handle these public-charge patients. But this falls far short of actual costs, say the administrators. New York City has promised to boost these payments to $20 a day in July and to make additional $1 and $2 yearly increases in the future.

With so much of their income controlled by the city governments and Blue Cross, hospitals say that a mere increase in their charges to private patients who are able to pay hospital bills will not be enough to solve their problems. "We raised our rates an average of 10 per cent last year and got only an additional $10,000 income," says an official of Knickerbocker Hospital.

FASTER MEDICARE BILLINGS ASKED

Medicare officials have expressed concern over the increasing number of delayed billings submitted under the Medicare program.

The office of the Surgeon General, United States Army, in a special bulletin, has presented the following information with regard to the submitting of claims

Delay in Medicare Billings—This office is concerned about the receipt of a large number of claims which have been delayed for a considerable period of time after completion of care. Delayed billings cause many problems for the Government, the contractors, the dependent or sponsor, and the source of care, all of whom are interested in settling the matter of payment as soon as practicable. From the Government's standpoint, the timely receipt of claims is most important in that the information therefrom is used as the basis for budgetary requests and other required statistical data.

Future Claims.—It is emphasized that Medicare contracts call for payment to be made on the basis of "complete" claims. Hospitals and physicians are urged to obtain all of the necessary information, including the Medicare Permit if required, or make arrangements for obtaining same, at the time the patient makes the initial visit and at the time the understanding is reached that care will be rendered under the Medicare Program. It is particularly important to examine the DD Form 1173 (Uniformed Services Identification and Privilege Card) and to obtain and record the required information therefrom, or to obtain adequate documentation establishing that the patient is an eligible dependent of an active duty member of the Uniformed Services. Physicians and hospitals are urged to submit claims as soon as care has been terminated. This will assist in cutting down correspondence required to complete the information necessary on the Claim Form for payment. With the passage of time, records may be misplaced and difficulty experienced in assembling all of the information required to submit a "complete" claim. Also, with the passage of time, the serviceman may be discharged or reassigned and he and the dependent may leave the area where care was received. In some cases, difficulty is encountered by the Uniformed Services in contacting the reassigned member or a former serviceman and his dependents after discharge.

Old Claims.—For the same reasons outlined above, physicians and hospitals are urged to "complete" and submit old claims, on hand, as soon as practicable. With the passage of time, it will become more and more difficult to process these claims and resolve difficulties which may arise in connection with them.

KEOGH-SIMPSON PASSES HOUSE

House passage of the Keogh-Simpson Bill (formerly the Jenkins-Keogh Bill) may be noted as another forward step designed to give major tax relief to doctors, lawyers and other self-employed persons.

Passage would allow such persons to deduct from taxable income, up to 10 per cent of self-employment earnings, up to a maximum of $2,500 a year, provided they put the money in certain specified types of retirement plans. This deduction could be taken for up to twenty years making a lifetime deduction of $50,000.

According to the provisions of the bill, sponsored by Representative Eugene J. Keogh (D., N. Y.), tax would not be paid on this income in the year it was earned, but only later when the individual retired and began drawing out money from the retirement fund. At that time, of course, he would in all likelihood be in a much lower tax bracket. Persons who are over fifty when the bill becomes law could defer taxes on considerably more than the $2,500 limit each year. The taxpayer could take the money back before retirement only on the payment of penalty taxes.

The program, opposed by the administration, passed the House last year, but Senate Finance Committee Chairman Harry F. Byrd (D., Va.) delayed consideration of the measure in the closing hours of the 85th Congress. Similar delaying tactics may be expected of Senator Byrd at this time. Proponents of Keogh-Simpson are hopeful that there may be forced action on the measure late this session or next year. The possibility of a presidential veto cannot be discounted.

Administration opposition is based on the theory that a $3 billion revenue loss will be experienced by the treasury. In addition, the treasury contends that the greatest benefits of the measure would be in favor of high income bracket individuals.

Members of the association and its auxiliaries are urged to write or wire Minnesota senators urging their support to H.R. 10. Address communications to Senator Hubert Humphrey and Senator Eugene McCarthy, (a member of Senator Byrd's committee), Senate Office Building, Washington 25, D.C.

MEDICINE AND THIRD PARTIES

Medicine recently has been much concerned by what is called "third parties." A third party has been defined as any mechanism which enters into the relationship between patient and physician.

The American Medical Association has not opposed these third parties as such, but it has expressed concern that an adverse effect on the selection of physicians, their compensation, and the quality of medical care rendered might occur because of the third parties' methods of operation and financial interest.

While the medical profession has been striving to attain full acceptance of the fundamental principle of the individual's right to choose his own physician, certain third parties in recent years have moved in the opposite direction. They arbitrarily select physicians for their members and require the members to use their services exclusively or pay for the services of another physician.

The abridgement of the patient's freedom of choice often occurs because of the third party's special interests. Likewise, methods of compensation other than fee-for-service, establishment of inequitable professional standards, and limitation of diagnostic and treatment services may be stimulated because of fiscal considerations rather than the needs of the patient or physician. In some plans promotional techniques may be developed that conflict sharply with traditional ethical methods for establishing a medical practice.

The interests of the patient and his medical care must come first. The patient must not be a pawn or captive or a third party. He should be free to select his own physician because that choice, in my opinion, is essential to the provision of the best medical care. Certainly experience has taught us that free choice generally establishes the confidence of the patient in his physician, a vital factor in successful therapy.

If Medicine abandons its historic support of the principle of free choice, it can expect increasing third party interference in decisions on predominantly professional matters.

The number of third parties is growing; the number of persons they serve is increasing. Unless medicine soon contains the influence of third parties on medical practice, it can expect the worst.

However, I believe that we can prevent the extension of third party influence by adhering uncompromisingly to the basic principle of free choice, by rendering competent medical care at a cost which patients can afford, by assuring the public of the competence of licensed physicians, and by policing our ranks to eliminate professional incompetence or economic abuses.

These must be self-imposed responsibilities that must be discharged vigorously now and in the future or Medicine may well find itself completely subservient to the third party!

—GUNNAR GUNDERSON, M.D.
President, AMA

Public Health

POLIO PROTECTION STEP-UP URGED BY MINNESOTA DEPARTMENT OF HEALTH

Minnesota had a light poliomyelitis year in 1958. Only twenty-five cases with one death were reported to the Minnesota Department of Health; twenty-three cases were paralytic.

Although Minnesota experienced its fewest number of polio cases in eleven years, polio epidemics are still possible unless a much greater proportion of the population is protected by vaccine, according to Dr. D. S. Fleming, director, division of disease prevention and control.

While it is difficult to say how much of the decline in cases since 1955 is due to immunization, Dr. Fleming points out that the Salk vaccine is the only proven, effective protection available to the public. He urges all unvaccinated persons to begin the full course of polio shots now.

He suggests that local antipolio campaigns be organized at once to see that vaccination programs are as effective this year as they were in 1957 when the Salk vaccine first became available. A nationwide program to stimulate local action has the support of national, state and local medical, public health, and voluntary agencies. Physicians are urged to make certain that all families they serve receive full benefit of the vaccine.

Whether immunizations are given in the physician's office, in school, or community programs should be determined by local physicians and the community. Even if everyone who is susceptible were vaccinated, one-fifth of the population would be subject to paralytic polio since the vaccine is only 80 per cent effective, according to Dr. Fleming.

A total of 4,620,438 cc. of polio vaccine had been shipped to Minnesota as of December 12, 1958, since the program got underway in 1955. Of all vaccine shipped into the state, 63 per cent has been from commercial sources; 32 per cent was federally subsidized in 1955-56; and 5 per cent was furnished by the National Foundation in 1955.

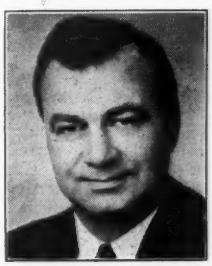
Physicians were required to report the use of federal vaccine, but the reporting of the use of commercial vaccine has been on an entirely voluntary basis. Even so, as of December 31, 1958, physicians had reported 2,852,125 inoculations, including 1,292,506 inoculations with commercial vaccine. This represents 44 per cent of all commercial vaccine that had been shipped into the state.

The 1,292,506 reported inoculations with commercial vaccine includes 392,484 first shots; 353,404 second shots; 540,189 third doses; and 6,429 fourth doses. All fourth shots were given in 1958.

Emphasis must continue to be on immunizing infants and youngsters, according to Dr. Fleming. Since the introduction of Salk vaccine, the highest rates of paralytic polio have occurred in children under five years of age. Of the estimated 384,631 children in the infancy to four-year age group, only 38 per cent have had three shots.

The second highest rates of paralytic polio per 100,000 population have occurred in children five to nine years of age. Of the 297,982 children in this age group, the state health department estimates that approximately 49 per cent have had three inoculations, based on reported shots.

Immunization of persons ten years of age or older has also lagged. About 32 per cent of youngsters ten to fourteen years of age have had three doses; approximately 19 per cent of youths fifteen to nineteen years of age; 13 per cent of persons in the twenty to thirty-five age group, which includes parents of young children and pregnant women; and 2 per cent of persons over thirty-five years of age.



Dr. Fleming points out that although first and second shots give protection, greatest antibody level is established only after the third shot. "Protection is not only greater; it is longer lasting," he states. Dr. Fleming urges a continuous immunization program against poliomyelitis.

Minnesota State Medical Association

106th Annual Meeting

Duluth, Minnesota—May 25-27, 1959

Guest Speakers

ROBERT J. ANDERSON, M.D.

Atlanta, Georgia

"Animal Diseases Transmissible to Man" will be the title of the presentation which will be given by Robert J. Anderson, M.D., Wednesday, May 27 at 11:00 a.m. Dr. Anderson is Assistant Surgeon General and Chief, Communicable Disease Center, Public Health Service, Department of Health, Education and Welfare.

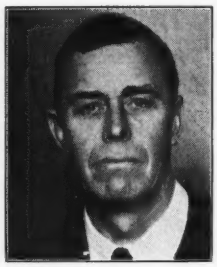
ELEXIOUS T. BELL, M.D.

Minneapolis, Minnesota

Elexious T. Bell, M.D., will present the Arthur H. Sanford Lecture in Clinical Pathology, Tuesday, May 26 at 11:30 a.m. "A Clinical and Pathological Comparison of Chronic Glomerulonephritis and Malignant Hypertension," is the title of Dr. Bell's presentation. Dr. Bell is Professor Emeritus, Department of Pathology, University of Minnesota. His appearance is sponsored by the Minnesota Society of Clinical Pathologists.

HERALD R. COX, Sc.D.

Pearl River, New York



Herald R. Cox, Sc.D., Director of Viral and Rickettsial Research, Lederle Laboratories, will participate in an "Oral Polio Vaccine" round table luncheon, Wednesday, May 27 at 12:15 p.m. In 1945, Dr. Cox was awarded the United States of America Typhus Commission Medal by the Secretary of War for his development of epidemic typhus vaccine, known as Cox-type or yolk-sac vaccine, which was adopted by the United States Army and Allied governments for immunization of military personnel against epidemic typhus fever. Dr. Cox's special fields of interest are the investigation of human and animal diseases of viral and rickettsial origin; the chemotherapy of viral and rickettsial agents; chemotherapy and viral antagonism of carcinogenic agents; and the chemistry of peptides and polypeptides.

JAMES W. CULBERTSON, M.D.

Memphis, Tennessee

James W. Culbertson, M.D., Professor of Medicine, College of Medicine, University of Tennessee, will participate in the opening panel discussion of the 106th Annual Meeting of the Minnesota State Medical Association, Monday, May 25 at 9:00 a.m. "What's New in Cardiovascular Disease" will be the discussion topic. F. J. Hirschboeck, M.D., of Duluth will be the moderator. Other members of the panel will be Henry I. Russek, M.D., of New York City and John W. Kirklin, M.D., Rochester. Dr. Culbertson is sponsored by the Minnesota Heart Association.

CUSHMAN D. HAAGENSEN, M.D.

New York, New York

Cushman D. Haagensen, M.D., Professor of Clinical Surgery, Columbia University, New York City, will participate in a Symposium on Breast Cancer, Monday, May 25, at 2:00 p.m. He will also participate in a 12:15 p.m. round table luncheon on Monday, on "Present Day Knowledge of the Etiology of Some Common Types of Cancer." Dr. Haagensen's appearance is sponsored by the Minnesota Division, American Cancer Society.

JOHN E. HARRIS, M.D.

Minneapolis, Minnesota

The Minnesota Academy of Ophthalmology and Oto-Laryngology Lecture will be presented Tuesday, May 26, at 11:00 a.m., by John E. Harris, M.D. Dr. Harris is Professor and Head, Department of Ophthalmology, University of Minnesota Medical School. Dr. Harris will also be the guest speaker at the Tuesday, May 26, luncheon of the Minnesota Acadamy of Ophthalmology and Oto-Laryngology, at 12:30 p.m. Dr. Harris is sponsored by The Minnesota Academy of Ophthalmology and Oto-Laryngology.

W. B. HILDEBRAND, M.D.

Menasha, Wisconsin

"Relationship of the General Practitioner to the Specialist" will be the address given by W. B. Hildebrand, M.D., at 9:30 a.m., Wednesday, May 27. Dr. Hildebrand, of Menasha, Wisconsin, is President of The State Medical Society of Wisconsin, and Past President of the American Academy of General Practice.

CAPTAIN JAMES R. KINGSTON

Medical Corps, U. S. Navy
Washington, D.C.

Captain James R. Kingston of the Medical Corps, U. S. Navy, will participate in two round table luncheons. On Tuesday, May 26, he will participate in the 12:15 p.m. luncheon "Immunization—Current Status." His second appearance will be on Wednesday, May 27, at the 12:15 p.m. luncheon "Oral Polio Vaccine."

JAMES E. LOFSTROM, M.D.

Detroit, Michigan

James E. Lofstrom, M.D., Chairman—Professor, Division of Radiology, College of Medicine, Wayne State University Detroit, Michigan, will present the Russell D. Carman Memorial Lecture, Monday, May 25, at 11:00 a.m. The title of his address will be "Breakthroughs in the Solution of the Stroke Problem." Monday afternoon at 4:00 p.m., he will participate in a panel discussion "Management of Strokes." In addition, Dr. Lofstrom will be the guest speaker at the dinner and annual meeting of the Minnesota State Radiological Society, scheduled for 6:00 p.m. at the Northland Country Club. Dr. Lofstrom is sponsored by the Minnesota Radiological Society.

MAURICIO MARTINS da SILVA, M.D.

Washington, D. C.

Mauricio Martins da Silva, M.D., Communicable Diseases Branch, Pan American Sanitary Bureau, Regional Office of the World Health Organization, Washington, D. C., will participate in the round table luncheon "Oral Polio Vaccine" at 12:15 p.m. on Wednesday, May 27.

THEODORE C. PANOS, M.D.

Little Rock, Arkansas

"Nutritional Requirements of the Neonate" will be the title of the Northwestern Pediatric Society Lecture which will be presented by Theodore C. Panos, M.D., Professor and Chairman, Department of Pediatrics, Medical Center, University of Arkansas, Little Rock, Arkansas, on Wednesday, May 27 at 11:30 a.m. He will also participate in a round table luncheon on "Nephrosis in Children" on Wednesday, May 27, at 12:15 p.m. Dr. Panos is sponsored by the Northwestern Pediatric Society and the Baker Laboratories, Inc., Cleveland, Ohio.

HENRY I. RUSSEK, M.D.

Staten Island, New York

Henry I. Russek, M.D., will participate in the panel discussion "What's New in Cardiovascular Disease" scheduled for 9:00 a.m., Monday, May 25. He will also participate in the Monday round table luncheon "Factors Responsible for the High Incidence of Clinical Coronary Atherosclerosis in the U. S." Dr. Russek is Consultant in Cardiovascular Research, U. S. Public Health Service Hospital, Staten Island, New York. He is sponsored by the Minnesota Heart Association.

CORNELIUS W. VERMEULEN, M.D.

Chicago, Illinois

Cornelius W. Vermeulen, M.D., will participate in a Symposium on Urological Problems, scheduled for Tuesday, May 26, at 2:00 p.m. His title in the Symposium will be "Formation of Stones." Dr. Vermeulen is Professor of Surgery (Urology), University of Chicago.

ROBERT I. WISE, M.D.

Philadelphia, Pennsylvania

"Resistance and Therapy" will be the presentation to be given by Robert I. Wise, M.D., at a Symposium on Staphylococcus Infections, scheduled for Wednesday, May 27, at 2:00 p.m. In addition, Dr. Wise will appear at a round table luncheon at 12:15 p.m. on Wednesday on "New Antibiotic Drugs." Dr. Wise is Magee Professor of Medicine and Head of Department of Medicine, The Jefferson Medical College of Philadelphia.

Sports Events and Outings

A full day of sports events, varied to suit the several tastes of the members of the Minnesota State Medical Association attending the Annual Meeting, have been scheduled for Sunday, May 24.

Major events are the Golf Tournament and the Skeet and Trap Shoot.

Golf Tournament

The Annual Golf Tournament will be held at Duluth's Northland Country Club. Tee-off time will be 10:00 a.m.-12:00 noon. Cocktails and Buffet have been scheduled for 5:00 p.m. Golfers and their wives are invited to attend.

Entry fee for the Golf Tournament is $5.00, and the tickets for the Buffet are $2.50 per plate.

Persons planning to participate are asked to make reservations on the card for that purpose enclosed with the Annual Meeting Program.

Skeet and Trap Events

The Annual Skeet and Trap Shoot will start at 10:30 a.m., at the Proctor Gun Club, just west of Proctor on Highway Number Two.

High Tower: Special twenty-five bird event at De Loia's Kennels, near Pike Lake, Highway Number 53. Time—2:30 p.m.

Pigeon Shoot: Live pigeons will be available for a special event following the Tower event if enough persons indicate they are interested.

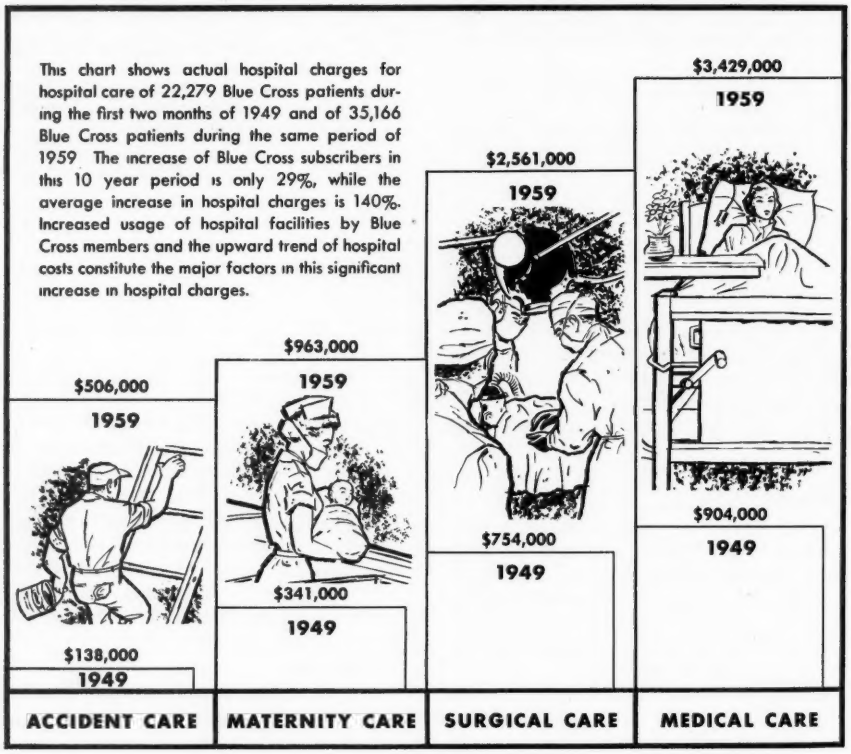
Trophies: The Malcolm Pfunder Skeet Trophy and the Vernon D. E. Smith Razzle Dazzle Trophy, both held for one year only, will be awarded. The Trap Committee Trophy of 1953, also a rotating trophy, will be awarded for trap shooting. Additional attractive prizes will be available. Make reservations for all shooting events with E. E. Barrett, M.D., on the reservation card enclosed with the Annual Meeting Program.

Boat Trips

Duluth-Superior Harbor and Lake Superior Boat Trips, viewing new St. Lawrence Seaway Terminus. Boats will leave on Sunday, May 24, at 3:00 p.m., and on Monday, Tuesday, and Wednesday at 10:00 a.m., and 3:00 p.m., at Lake Avenue Dock for two-hour trips.

Price—$2.00 for adults and $1.00 for children under 12. Make reservations with C. M. Bagley, M.D., on the card enclosed for that purpose with the Annual Meeting Program.

Minnesota Blue Shield—Blue Cross



The fact that utilization of the Blue Shield contract by participant subscribers continued to increase during 1958 is shown by a comparison of the number of services of physicians provided Blue Shield benefits per 1,000 contracts and per 1,000 subscribers during 1958 and 1957.

During 1958, Blue Shield provided benefits for 1,109 physicians' services per 1,000 contracts, or 416 services per 1,000 participant subscribers. In the previous year, 1957, Blue Shield benefits were provided for 963 services of physicians per 1,000 contracts, and 362 services per 1,000 participant subscribers. These figures clearly illustrate the increased incidence and utilization experienced by Blue Shield in 1958 over 1957. During 1958, Blue Shield benefits were provided for well over one service for every contract in effect, while during 1957 benefits were provided for slightly less than one service for each contract in effect.

Percentage-wise, the increase in the number of doctors' services provided Blue Shield benefits per 1,000 subscribers and per 1,000 contracts in 1958 over 1957 is approximately 15 per cent. This percentage increase also illustrates the increased incidence and utilization experienced by Blue Shield in 1958.

During 1958, a total of 365,654 services of doctors were provided Blue Shield benefits, while during 1957 Blue Shield provided benefits for 307,171 physicians' services rendered subscribers. The number of services for which Blue Shield provided benefits in 1958 is approximately 19 per cent greater than the number of services provided benefits during 1957.

10 YEAR COMPARISON OF HOSPITAL CHARGES FOR BLUE CROSS PATIENTS

The Art of Medicine

Carl H. Woyke, B.A.
Editor

YOU CAN OFFER PERSONAL AND FAMILY HEALTH RECORDS

How often have you asked a patient one of these questions: "Are you allergic or sensitive to certain drugs or other substances?" "What is your blood type?" "Who is your personal physician?" "Your next of kin?" "Have you received vaccination for polio, tetanus, smallpox, typhoid?"

Needless to say, you have frequently tended the needs of a person who is unconscious due to severe illness, injury or shock, or some other situation which has made it impossible for the person to speak for himself.

Here's the opportunity for members of the Minnesota State Medical Association to help provide accurate answers to these questions which may some day mean the difference between the life and death to the person involved. Because having important personal health facts readily available for any health emergency is so important, you, the members of the Minnesota State Medical Association are used to co-operate in the distribution of personal and family health records to your patients.

The billfold size personal health records, provide space only for essential health information. More detailed information may be recorded in the family health records. Both forms are available in quantity without charge from the Minnesota State Medical Association, 496 Lowry Medical Arts Building, St. Paul 2, Minnesota.

PROGRAM CHAIRMAN—HERE'S A TIP

Are you a Program Chairman charged with the responsibility of providing a worthwhile presentation at your next County Medical Society, Lion's Club, American Legion, or congregational men's club meeting? Why not select an appropriate title from sound films available through the Motion Picture Library, American Medical Association. Available are films for every occasion or purpose—titles for professional and lay-audience groups alike.

For many films, there is only a return-shipping charge required. For others, a minimum film rental is charged. Lists of available films from the Motion Picture Library of the American Medical Association, are available from the Minnesota State Medical Association, 496 Lowry Medical Arts Building, St. Paul 2, Minnesota.

The following is only a partial list of the various films available.

"The Man Who Didn't Walk"—Black and white, sound, 1145 feet, showing time 32 minutes. Produced by Dynamic Films, Inc., New York, for The Wm. S. Merrell Co., The American Bar Association, and the American Medical Association. Recommended for Professional groups only.

This, the third film in the series on doctor and lawyer relations, develops a case of traumatic neurosis. Medical examinations and court room procedure are used to show areas of conflict. The film testimony of competent experts represents two entirely different viewpoints.

"San Francisco Highlights (1958)"—Black and white, sound, 1073 feet, showing time 30 minutes. Presented by the American Medical Association in co-operation with Merck Sharp and Dohme.

Abstracts of some of the papers presented during the 1958 Annual Meeting of the American Medical Association. Includes a discussion on cancer and viruses by Wendell M. Stanley, a report on hypnosis by Milton J. Marmer, a study on blood alcohol levels among drivers killed in single vehicle accidents, an interview with Col. John P. Stapp who rode a rocket driven sled and an interview with Charles E. MacArthur who introduced the program of annual physical examinations for physicians.

"Choosing A Doctor"—Black and white, sound, 500 feet, showing time 14 minutes. Produced by Crawley Films, Toronto, for McGraw Hill Book Co.

Fred Morris' young daughter had an appendicitis attack and he didn't know where to turn . . . until he remembered a "doctor" he had met on the golf course. Fred was lucky . . . he hit upon a reputable physician, but he learned the lesson that only a wisely selected personal physician will afford the peace of mind and the knowledge that his family will be protected with competent medical care at all times.

"Helping Hands for Julie"—Black and white, sound, 973 feet, showing time 27 minutes. Produced by Henry Strauss & Co., Inc., New York for the American Medical Association, American Hospital Association, and E. R. Squibb & Sons.

This is a film on career opportunities in medicine and health. The story of Julie revolves around her fight for life when she is brought into the hospital emergency room—diagnosis: unknown. The helping hands aiding the doctors in this vital search for the correct diagnosis are those of nurses, medical technologists, x-ray technicians and the medical record librarian. The film is designed to attract students into these careers by dramatizing their opportunities.

"The Medicine Man"—Black and white, sound, 973 feet, showing time 27 minutes. Produced by Monopegic Productions, Hollywood, for the American Medical Association.

How "medicine men" dupe the public into spending millions of dollars on unnecessary or over-priced nutritional products is shown in this film. It dramatically pinpoints the fight against quackery in the food and nutrition field.

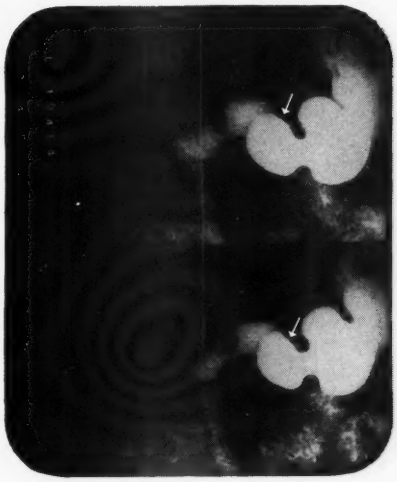
"Red River of Life, Part 1"—Color, sound, 1028 feet, showing time 28 minutes. Prepared by the Moody Institute of Science, West Los Angeles, California.

This film, which deals primarily with the heart and the circulatory system, compares the human body with an automobile engine and shows how they both have need of fuel and removal of waste. How the valves of the heart work under varying conditions of high and low blood pressure and even shock is seen by means of pictures of the valves in action which were taken with the cardiac pulse duplicator. An x-ray motion picture shows a plastic artificial heart valve at work in a patient and the heart lung machine is explained.

DOCTORS' BUSINESS PRACTICES REFLECT PROFESSIONAL PUBLIC RELATIONS

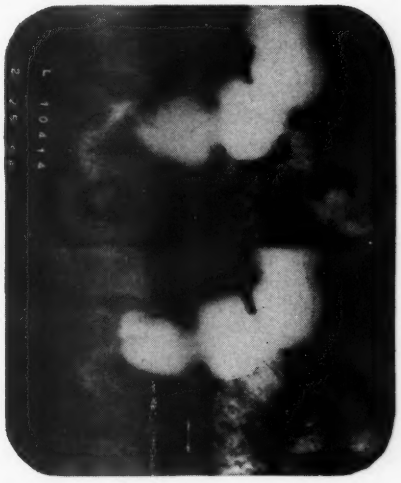
Physicians should remember that one doctor or medical secretary who treats the patient rudely can erase the good impression created by ten thoughtful colleagues, is the advice given in *PR Doctor* issued by the Communications Division of the AMA.

In order to emphasize the value of sound business practices and the importance of good doctor-patient relationships, the following case history and subsequent advice was given by *PR Doctor*:



Recently a letter was received from a public relations man whose personal brush with a medical group's business methods prompted him to give some professional advice—gratis.

The man's wife had recently undergone surgery and he had been incensed to find the surgeon's bill placed alongside her hospital bed four or five hours after the operation. This practice plus the answer he received to his letter of complaint, he felt, left something to be desired in at least one group of doctors' public relations program. So he paid his bill but included this advice:



"Medical people should learn that no matter how much they want to operate like a commercial business, to sell services as one does shoes, they can never turn this trick because doctors are called in when people are in trouble. In an emotional situation, business logic disappears. Even if doctors are right from a purely business point of view they cannot escape the fact that the recipient of the services does not view it as a business situation at the time of crisis."

The gist of the man's recommendation is pure and simple finesse. Medical business practices should never be so crass that they shock perfectly intelligent and cooperative patients. Letters of complaint (no matter who is at fault) should never be answered curtly or in a tone of indignant righteousness.

—and control its G.I. sequelae

Patient A.S., age 53.
Intermittent crises of severe pain over 2 year period; hospital management with Sippy regimen provided relief of symptoms; however, symptoms recurred after each sojourn.

PATHIBAMATE *(Tabs. j t.i.d. and H.S.);* prompt relief of symptoms. Radiograph (21 days later) confirms healing of minute lesser curvature gastric ulcer crater.

predictable results in the control of tension and G.I. trauma

Pathibamate®

Meprobamate with PATHILON® Tridihexethyl Chloride* LEDERLE

Used prophylactically in anticipation of periods of emotional stress, or therapeutically to relieve tension and curb hypermotility and hypersecretion, PATHIBAMATE is particularly well-formulated for the control of gastrointestinal disorders.

PATHIBAMATE combines Meprobamate (400 mg.) — the noted tranquilizer-muscle relaxant widely accepted for safe management of tension and anxiety states — and PATHILON (25 mg.) — an extremely well-tolerated anticholinergic, long noted for prompt symptomatic relief based on peripheral atropine-like action with few side effects.

Indications:
Duodenal ulcer, gastric ulcer, intestinal colic, spastic and irritable colon, ileitis, esophageal spasm, anxiety neurosis with gastrointestinal symptoms, gastric hypermotility.

Supplied:
Bottles of 100 and 1,000. Each tablet (yellow, ½-scored) contains Meprobamate, 400 mg.; PATHILON Tridihexethyl Chloride, 25 mg.

Administration and Dosage:
1 tablet three times a day at mealtimes and 2 tablets at bedtime. Adjust dosage to patient response. Contraindicated in glaucoma, pyloric obstruction, and obstruction of the urinary bladder neck.

Also Available: PATHILON in four forms — *Tablets* of 25 mg., plain (pink) or with *phenobarbital*, 15 mg. (blue);
Parenteral — 10 mg./cc. — 1 cc. ampuls;
Pediatric Drops — 5 mg./cc. — dropper vials of 15 cc.

*PATHILON is now offered as tridihexethyl chloride instead of the iodide, an advantage permitting wider use, since the latter could interfere with the results of certain thyroid function tests.

AMA ANNUAL MEETING WILL FEATURE 450 PHYSICIAN SPEAKERS

Hypnosis, staphylococcal infections, blood cell disorders, space medicine, European spas, and aging are among the subjects to be considered at the 108th Annual Meeting of the American Medical Association, June 8-12, in Atlantic City.

Some 450 physicians will present scientific papers or participate in panel discussions and symposiums during the meeting. In addition, there will be 387 scientific exhibits shown by physicians and 285 industrial exhibits prepared by pharmaceutical houses, medical equipment firms, and other business organizations.

Most of the scientific sessions, along with the exhibits, will be held in the Atlantic City Convention Hall. Some scientific meetings will be held in hotels.

Seven of the twenty-one sections of the scientific assembly mark their 100th anniversaries during the meeting. They are the sections on surgery, internal medicine, obstetrics and gynecology, experimental medicine and therapeutics, pathology and physiology, nervous and mental diseases, and preventive medicine.

Other features of the scientific program will include color television and motion pictures. Two films of special interest to be premiered deal with staphylococcal infections in hospitals and radiation protection in diagnostic radiologic examinations.

The House of Delegates, with its 210 members, will meet throughout the week in the Traymore Hotel, headquarters for the meeting. The House will select a physician to receive the Distinguished Service Award at its opening session Monday morning, June 8. Winner of the Goldberger Award, given for outstanding contributions in the field of nutrition, will also be announced Monday. The winner will present the annual Goldberger lecture at the opening of the general scientific session Monday afternoon.

Dr. Louis M. Orr, Orlando, Florida, will be inaugurated president of the AMA Tuesday evening. The inaugural will be followed by a reception and ball. Lester Lanin and his twenty-piece orchestra, internationally known dance band, will provide the music for the ball in Convention Hall.

MONOGRAPH PRIZES OFFERED BY THE AMERICAN ACADEMY OF ARTS AND SCIENCES

Three prizes of $1,000 each will be awarded annually to the authors of especially meritorious unpublished monographs, one each in the fields of the Humanities, Social Sciences, Physical and Biological Sciences.

A monograph is defined for the purposes of these awards as a "scholarly contribution to knowledge, too long for an article in a learned journal and too specialized or too short for a general book." Final date for receipt of manuscripts is October 1, 1959. For further information write the Committee on Monograph Prizes, American Academy of Arts and Sciences, 280 Newton Street, Brookline Station, Boston 46, Massachusetts.

1959 RURAL MEDICAL SCHOLARSHIP WINNER NAMED

The Rural Medical Scholarship recipient for 1959 is LeRoy Earl Mueller, a native of Belle Plaine, Minnesota. He received his premedical college training at Gustavus Adolphus College of St. Peter, Minnesota, and is a member of the freshman class in the University of Minnesota Medical School.

LeRoy Mueller is the seventh person to receive this scholarship established by the Association to assist worthy and outstanding students to meet the expense of a medical education, as well as to help insure a supply of physicians in non-metropolitan Minnesota communities.

According to the provisions of the scholarship, LeRoy Mueller will receive $1,000 each year for four years on the condition that he promises to practice medicine for at least five years after graduation from medical school in a rural Minnesota community.

Previous Rural Medical Scholarship winners now practicing medicine include Dr. Richard Engwall, Ivanhoe, and Dr. Leland Christenson, Maple Plain. Interning at Bethesda Hospital, St. Paul, is Myron Doebler, Princeton. Attending the University of Minnesota Medical School are Carl E. Christenson, Stanchfield, Senior; Vincent R. Hunt, Anoka, Junior, and Edward S. Peterka, Aurora, Sophomore.

NEUROPHYSIOLOGY RESEARCH FUNDS AVAILABLE

The Dysautonomia Association has announced that funds are now available for basic or clinical research in neurophysiology.

The Association will support research related to the clinical entity known as familial dysautonomia, a disease caused by dysfunction of the autonomic nervous system. It will also support any type of study that might lead to a better understanding of nervous system functions at a basic level as a stepping stone to the understanding of a disease process.

The Association will submit all requests for grants to its medical advisory board for evaluation. Requests should

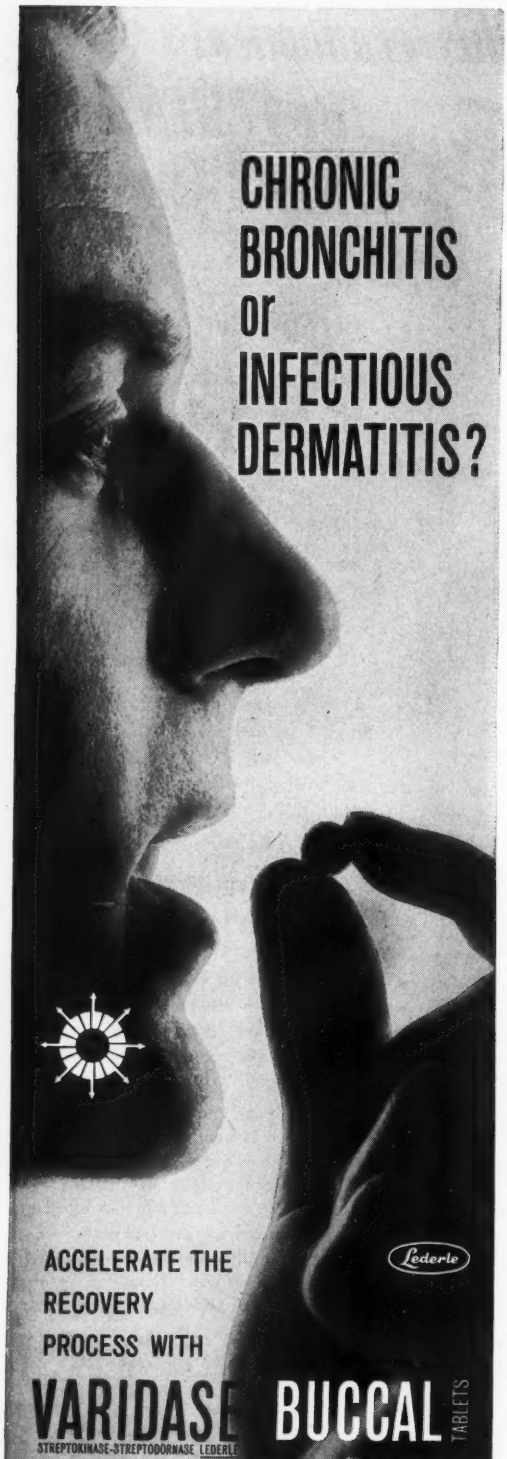
P&H *TREATMENT TABLE*

meets the need for efficiency and high quality

STURDY—FINELY CONSTRUCTED—MADE OF GENUINE CANADIAN BIRCH



With the growth of the medical clinic there has come the need for a new type of table. The P&H TREATMENT TABLE meets that need with both style and economy. We know you will agree that this is the best table value in years. It is a quality table that you will be proud to own and will, we are sure, find it an excellent table for your "second" examination room.

This sturdily constructed table is made of the finest genuine Canadian Birch—solid wood legs and rails with birch-face five-ply panels for drawer and door fronts. It is offered in one standard finish only—natural wood in a golden blond color. It has six drawers and one compartment accessible from either side. There is a three position headrest, sliding stirrups, sliding leg rest and foot step. Upholstered with brown DuPont Fabrilite with 2" of padding.

DIMENSIONS:
Length 48", fully extended 68", width 22" height 32".

OPENINGS IN GRADUATE COURSES

The Post-Graduate Medical School of the New York University-Bellevue Medical Center announces a few openings in graduate courses available during the 1959-1960 academic year. They may be taken as part of a residency program or in preparation for specialty board examinations.

Courses in the following fields are offered: Anesthesiology, Dermatology and Syphilology, Medicine, Orthopedic Surgery (January 1960), Otorhinolaryngology, Radiology, Surgery.

Further information may be obtained by writing or phoning the Office of the Associate Dean, New York University Post-Graduate Medical School, 550 First Avenue, New York 16, N. Y.

SYMPOSIUM ON DISEASES OF THE LIVER AND BILE DUCTS

A Symposium on Diseases of the Liver and Bile Ducts will be presented by the Lake Region Hospital Staff and Park Region Medical Society at Fergus Falls, Minnesota, on June 20, 1959. The following is an outline of the program:

Physiology of the Liver—ARTHUR SETHRE, M.D., Fergus Falls, Minnesota
Diagnostic and Laboratory Procedures—JAMES B. CAREY, M.D., Department of Medicine, University of Minnesota
X-ray Investigation—WARD SHAVER, M.D., Fergus Falls, Minnesota
Jaundice—WILLIAM SUMMERSKILL, M.D., Department of Gastroenterology, Mayo Clinic, Rochester
Cirrhosis of Liver—JOHN HUTCHINSON, M.D., Department of Medicine, University of Minnesota
Surgical Aspects
Gallstone Diseases—P. H. T. THORLAKSON, M.D., University of Manitoba, Winnipeg, Canada
Common Duct Diseases—GEORGE HALLENBECK, M.D., Department of Surgery, Mayo Clinic, Rochester
Neoplastic Diseases—RICHARD VARCO, M.D., Professor of Surgery, University of Minnesota

Credit will be allowed by the Minnesota Academy of General Practice for this symposium.

EXHIBITION OF ART WORKS BY AMERICAN PHYSICIANS

The 22nd Annual Exhibition of Art Works by American Physicians will take place June 8 through June 12 at Convention Hall in Atlantic City, according to Richard H. Gwartney, President of the American Physicians Art Association.

Held in conjunction with the annual convention of the American Medical Association, the show will include more than 550 works of art in oil, water color, sculpture, crafts, photography and lithography.

Participants and prospective exhibitors may obtain further information from Regional Director, F. A. Zinter, M.D., 600 Physicians and Surgeons Building, Minneapolis 2, Minnesota.

. . . and one to grow on

A tiny tablet of REDISOL to stimulate the appetite — to help in the intake of food for growth.

REDISOL is crystalline vitamin B_{12}, an essential vitamin for growth and the fundamental metabolic processes.

Ideal for the growing child, the REDISOL tablet dissolves instantly on contact in the mouth, on food or in liquids.

Packaged in bottles hermetically sealed to keep the moisture out and to retain vitamin potency in 25 and 50 mcg. strengths, bottles of 36 and 100 — in 100 mcg. strength, bottles of 36, and in 250 mcg. strength, vials of 12.

Also available as a pleasant-tasting cherry-flavored elixir (5 mcg. per 5-cc. teaspoonful) and as REDISOL injectable, cyanocobalamin injection USP (30 and 100 mcg. per cc., 10-cc. vials and 1000 mcg. per cc. in 1, 5 and 10-cc. vials).

Woman's Auxiliary

DULUTH HOSPITALITY WILL SPARK THIRTY-SEVENTH ANNUAL MEETING

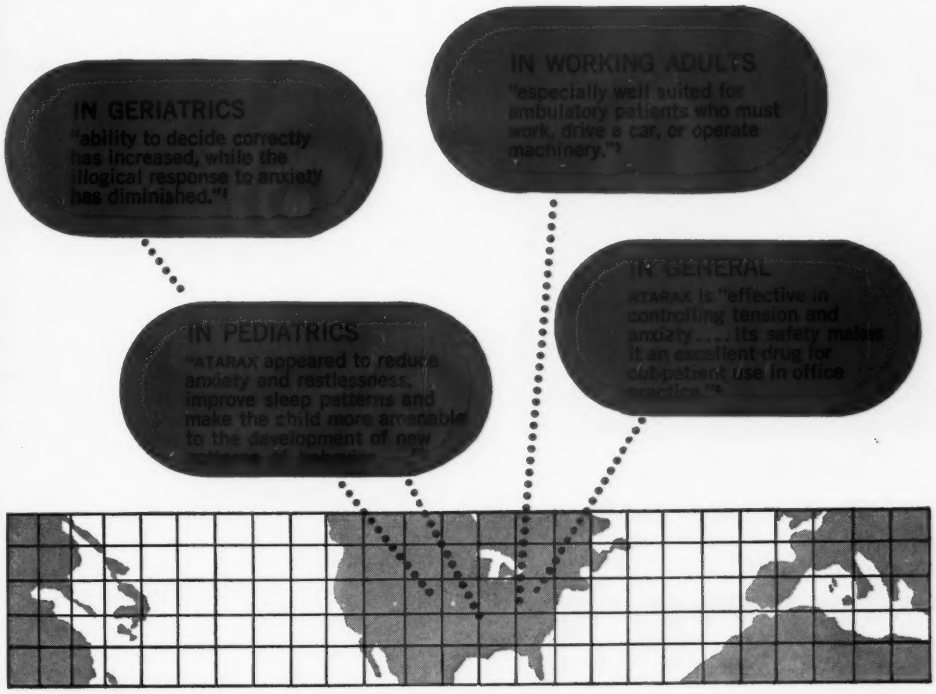
The Woman's Auxiliary to the St. Louis County Medical Society, hostesses for the Thirty-Seventh Annual Meeting, have pledged to make this a memorable occasion for all members attending. Arrowhead country hospitality will be the spark from the opening registration on Monday, May 25, at 9:00 a.m. to the closing "Round-Up Breakfast" on Wednesday, May 27, at 10:30 a.m.

Monday's get-acquainted activities will feature the Executive Board Meeting and Luncheon, at 10:30 a.m. and 1:00 p.m., respectively, in the Kitchi Gammi Club. At 3:00 p.m., all visiting women are cordially invited to be guests of the St. Louis County Medical Auxiliary at a Tea at the Tweed Art Gallery on the University of Minnesota, Duluth Campus. At 9:00 p.m., the annual Open House for all auxiliary members and their physician husbands, will be held in the Ballroom of Hotel Duluth.

The Annual Business Session, open to all auxiliary members, will begin at 9:30 a.m., Tuesday, May 26, in the Arrowhead Room of Hotel Duluth. Presiding will be Mrs. Reuben F. Erickson, State President. Other members participating in the Annual Meeting program activities include Mrs. William Finkelnburg, Winona, who will lead the Pledge of Allegiance; Mrs. John W. Stuhr, Stillwater, who will lead the Auxiliary Pledge; Mrs. Gordon Strewler, Duluth, President, St. Louis County Medical Auxiliary, giving the Address of Welcome; Mrs. Rodney Sturley, St. Paul, who will give the Response; Mrs. A. M. Jensen, Brownton, who will lead the In Memoriam Service with music by Mrs. A. C. Hilding, Duluth.

Mrs. Aaron Margulis, Santa Fe, New Mexico, National Committee Chairman for Mental Health, will be the guest speaker at the annual luncheon scheduled for 1:00 p.m. in the Ballroom of the Hotel Duluth. "The Physician's Wife—Generalist" will be the title of Mrs. Margulis' address. Mr. Eugene Lambert, former Mayor of Duluth, will also address the luncheon guests. His topic will be "What the Seaway will mean to Minnesota."

Other luncheon program activities will include the installation of officers; installation of president and presentation of president's pin; presentation of gavel, and the greetings from the new president. Following the conclusion of the luncheon activities, the post convention Board meeting will be held in the Arrowhead Room.



Tuesday's activities will conclude with the annual banquet for members of the Minnesota State Medical Association and auxiliary members at 7:00 p.m. in the Ballroom of Hotel Duluth. Presiding will be Dr. Benjamin B. Souster, President of the Minnesota State Medical Association. Dr. E. W. Ziebarth, Dean, Summer Session, University of Minnesota, will present the address of the evening. "Russia Today" will be the title of Dr. Ziebarth's address.

DULUTH HOSPITALITY WILL SPARK THIRTY-SEVENTH ANNUAL MEETING

(Continued from Page 630)

Additional introductions and presentations scheduled for the banquet include: Introduction of Mrs. M. F. Fellows, President, Woman's Auxiliary; and presentation of Fifty-Club Certificates, the Southern Minnesota Medical Association Medal and the Distinguished Service Award.

A "Round-Up Breakfast," scheduled for Wednesday, May 27, at 10:30 a.m. will climax the activities of the annual meeting.

REGION THREE HOLDS LUNCHEON MEETING

A Region Three luncheon meeting was held in Montevideo, recently, at the home of Mrs. William Miller, with Mrs. John Allen assisting her.

Mrs. M. I. Hauge, Region Three Advisor, was in charge of the meeting. Twenty members of the auxiliary, representing three county auxiliaries, were present.

Honor guests were Mrs. Reuben F. Erickson, State President, and Mrs. M. F. Fellows, State President-Elect. Mrs. Fellows extended greetings to Region Three. Mrs. Erickson gave a résumé of some phases of auxiliary work and told how small auxiliaries could work on some of the state projects.

The meeting closed with a talk on safety by Mrs. E. R. Hudec, State Safety Chairman.

AMA CONVENTION HIGHLIGHTS LISTED

The thirty-sixth annual meeting of the Woman's Auxiliary to the American Medical Association will be held June 8-12, 1959, at the Haddon Hall Hotel, Atlantic City, New Jersey. Hostesses for the occasion will be the Woman's Auxiliary to the Medical Society of New Jersey and the Woman's Auxiliary to the Atlantic County Medical Society.

The hosting groups have extended a most cordial invitation to all auxiliary members as well as other wives and guests of physicians attending the convention, to participate in the social functions and to sit in on the general sessions.

According to Margaret N. Wolfe, Executive Secretary, Atlantic City's natural attractions are almost too well known to need mention at this time. Perhaps the most famous feature of the city—which is actually located on an island five miles at sea and connected with the mainland by causeways—is the unique boardwalk. Sixty feet wide for much of its five-mile length, the boardwalk is constructed of steel and concrete and overlaid with pine planking in herringbone pattern. (Twenty miles of planks are required each year just to keep the boardwalk in good repair.) The city side is lined with huge hotels, blocks of fine stores and shops, restaurants, exhibit rooms, and theaters.

Auxiliary members are urged to make reservations at once.

when pollen allergens attack the nose...

Triaminic provides more effective therapy in respiratory allergies because it combines two antihistamines[1,2] with a decongestant.

These antihistamines block the effect of histamine on the nasal and paranasal capillaries, preventing dilation and exudation.[3] *This is not enough;* by the time the physician is called on to provide relief, histamine damage is usually present and should be counteracted.

The decongestive action of orally active phenylpropanolamine helps contract the engorged capillaries, reducing congestion and bringing prompt relief from nasal stuffiness, rhinorrhea, sneezing and sinusitis.[4,5]

TRIAMINIC is orally administered, systemically distributed and reaches *all* respiratory membranes, avoiding nose drop addiction and rebound congestion.[6,7] TRIAMINIC can be prescribed for prompt relief in summer allergies, including hay fever.

Triaminic®

TRIAMINIC provides around-the-clock freedom from hay fever and other allergic respiratory symptoms with just one tablet q. 6-8 h. because of the special timed-release design.

Each TRIAMINIC timed-release tablet provides:

Phenylpropanolamine HCl	50 mg.
Pheniramine maleate	25 mg.
Pyrilamine maleate	25 mg.

Also available: TRIAMINIC SYRUP for those patients of all ages who prefer a liquid medication. Each 5 ml. teaspoonful is equivalent to ¼ Triaminic Tablet or ½ Triaminic Juvelet. TRIAMINIC JUVELETS provide half the dosage of the Triaminic Tablet with the same timed-release action for prompt and prolonged relief.

TUBERCULOSIS CONTROL IN THE HOSPITAL

To: Chiefs of Staff— Roentgenologists—Administrators of all licensed hospitals in Minnesota

Dear Doctor:

In order to protect the hospital patient and hospital personnel against tuberculosis, the Committee on Pulmonary Diseases of the Minnesota State Medical Association recommends that each staff set up its own "PROTECTION PROGRAM."

Since the routine admission chest X-ray film is the common screening agent, it is suggested that the following plan may be effective when the roentgenologist sees a film suggestive of tuberculosis:

1. That he immediately notify the attending physician, the administrator, and the chairman of the hospital infection committee.
2. That the responsibility for isolation and diagnosis of the lesion rests with the attending physician.

The details of this suggested method should be modified to meet the needs of the individual hospital.

Sincerely,
JOHN F. BRIGGS, M. D.

Saint Paul, Minnesota
March 6, 1959

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

ERROR IN IDENTIFYING DRUG

Dear Doctor:

Through an error in this section, a drug was wrongly identified in the article by Drs. Winkelmann and Brunsting that appeared in your January issue.

We and the authors would appreciate having it set right by publication of a note:

ERRATUM

"Edathamil disodium (calcium disodium) versenate" in lines 37-38, right column, page 14 of the January, 1959, issue should read "edathamil disodium (disodium versenate)."

We are sorry to have committed this mistake that involved your journal, and hope we have chosen the most effective and least troublesome way to correct it.

Yours truly,
GUY WHITEHEAD, PH.D.
Consultant

Mayo Clinic
Section of Publications
Rochester, Minnesota
April 14, 1959

NEW FORMAT APPROVED

We have received our April, 1959, issue of the "Minnesota Medicine." We are delighted with the cover page and we think that you have done very well with this, indeed. We also want to compliment you on the manner in which you handled the beginning of scientific articles. The generous use of "white space" certainly contributes an effective and attractive presentation of the material.

You and your staff are certainly making progress that you should be very proud of.

Sincerely,
J. P. SANFORD

To the relief of musculoskeletal pain, new MEDAPRIN* adds restoration of function

Analgesics offer temporary relief of musculoskeletal pain, but they merely *mask* pain rather than getting at its *cause*. New Medaprin, in addition to bringing about prompt subjective improvement, promotes the *restoration of normal function* by suppressing the inflammation that *causes* the pain.

Medaprin, Upjohn's new analgesic-steroid combination, contains aspirin plus Medrol,** the corticosteroid with *the best therapeutic ratio in the steroid field.*† Instead of suffering recurrent discomfort because of the "wearing off" of analgesics, the patient on Medaprin experiences a smooth, *extended* relief and more normal mobility.

Indications: Medaprin is indicated in mild-to-moderate rheumatic and musculoskeletal conditions, including rheumatoid arthritis, deltoid bursitis, low back pain, neuralgia, synovitis, fibromyositis, osteoarthritis, low back sprain, traumatic wrist, sciatica, and "tennis elbow."

Dosage: The recommended dosage is 1 tablet q.i.d. The usual cautions and contraindications of corticotherapy should be observed.

Supplied: In bottles of 100 and 500.

Formula: Each Medaprin tablet contains

- 300 mg. acetylsalicylic acid, for prompt relief of pain
- 1 mg. Medrol, to suppress the causative inflammation
- 200 mg. calcium carbonate, as buffer

In Memoriam

CHARLES NORTON HENSEL

Dr. Charles N. Hensel, a prominent internist of St. Paul for many years, died on April 6, 1959, at the age of seventy-seven.

Dr. Hensel was born in Fargo, North Dakota, March 3, 1882, the son of John Henry Hensel and Anna Cecelia Norton and came to St. Paul at an early age. He graduated from Mechanic Arts High School and took three years in the College of Science, Literature and Arts at the University of Minnesota before taking the medical course, from which he graduated in 1908. He was a charter member of the Minnesota chapter of the Sigma Alpha Epsilon fraternity at the University and was a member of the Epsilon chapter of the medical fraternity, Nu Sigma Nu. He maintained his interest in Nu Sigma Nu and for a number of years was president of the Twin City Alumni Association of the fraternity, and was active in obtaining support of the Epsilon chapter by the alumni.

After graduation from medical school, Dr. Hensel interned at the Ancker Hospital in St. Paul and opened an office in the Moore Building at Seven Corners in January, 1910. He was associated with Dr. Charles Lyman Greene for a number of years. He took postgraduate work at the Harvard Medical School in the summer of 1917 and two six-month periods in Vienna in 1926 and 1928. For many years, he maintained offices in the Lowry Medical Arts Building and in January, 1958, became a member of the Fifty Club of the Minnesota State Medical Association after fifty years of medical practice.

Dr. Hensel was a member of the medical staff of St. Luke's, Miller, St. Joseph's, and Children's Hospitals. For a period of twenty years, he and Dr. E. Mendelsohn Jones conducted the staff meetings at Miller Hospital, and he was chairman of the medical division of the Hospital Building Fund campaign of Miller Hospital in 1948 when the Harry Zimmermann Wing was built.

He was especially interested in cardiology and allergy and published some fourteen articles in the field of internal medicine. He was president of the Minnesota Heart Society in 1954. He became a member of the Minnesota Academy of Medicine in 1932 upon presentation of his thesis entitled "Pitfalls in Cardiac Diagnosis," and served as president of the society in 1954. He was also a charter member of the Minnesota Society of Internal Medicine, which was founded in 1926, and became its president in 1938. Besides being a member of the Ramsey County Medical Society, the Minnesota State Medical Association, and the American Medical Association, he was a member of the American Board of Internal Medicine, the American College of Physicians, the Association for the Study of Allergy, the Association for the Study of Internal Secretions, the Minnesota Pathological Society, the Southern Minnesota Medical Association, and the St. Paul Clinical Club.

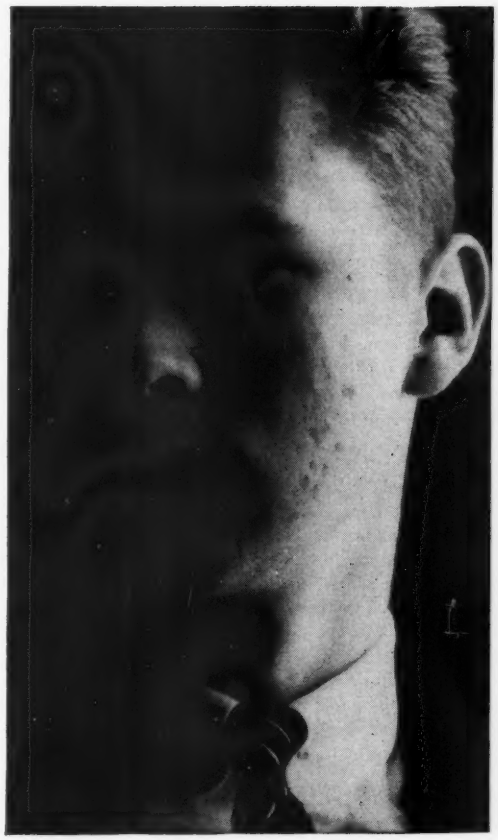
Dr. Hensel's interest in public speaking dates back to his high school days when he took part in dramatic presentations at Mechanic Arts High School. He continued his interest in dramatics at the University by taking part in the presentation of Shakespearian plays by the University Dramatic Society. He became a forceful speaker which contributed to his success in his chosen profession. He was a voracious reader and devoted to his profession. He was also an enthusiastic traveller, and he and Mrs. Hensel had visited Europe on five different occasions in addition to the two trips to Vienna in the twenties.

He was a member of St. John the Evangelist Episcopal Church and as a young man, sang in the church choir.

Dr. Hensel is survived by his wife, Florence (Schmit); a son, Carl N. of Wayzata; a daughter, Mrs. Richard (Lillian) Tyner of Alexandria, Virginia; a brother, Elliott C., of Glendale, California; and eight grandchildren.

JOHN J. McGROARTY

Dr. John J. McGroarty, who practiced medicine in Easton for sixty years, died April 6, 1959. He was seventy-eight years of age.



Dr. McGroarty was a native of Inver Grove, Minnesota, and received his preliminary education in the schools of that community and St. Thomas College of St. Paul. He moved to Easton following completion of his internship at Ancker Hospital, St. Paul. He graduated from the University of Minnesota School of Medicine in 1907.

Dr. McGroarty was granted life membership in the Minnesota State Medical Association in 1955 and became a member of the Fifty-Year Club in 1958. In 1956, Dr. McGroarty was named Rural Doctor of the Year at the National Catholic Rural Life Conference.

A member of the Blue Earth Valley Medical Society, he was also a member of the American Medical Association.

Dr. McGroarty is survived by his wife, Theresa, of Easton; a son, Dr. Brian McGroarty of St. Paul; two sisters, Mrs. Mary Corrigan, St. Paul, and Sister M. Basil, Minneapolis; two brothers, Bryan, St. Paul and William, Los Angeles.

The Physician's Diary

Dr. Stephen Silvis, who left Spring Valley for the Navy in 1957, returned recently and resumed his partnership with **Dr. N. J. O'Keefe.** Dr. Silvis and his family were stationed for two years in Hawaii.

* * *

Seven new consultants—six of them former Mayo Foundation fellows—have been named to the staff of the Mayo Clinic. The seven new consultants are: **Dr. Thomas L. Brannick,** consultant in psychiatry; **Drs. Arnold L. Brown, Jr.,** and **Chris A. Pascuzzi,** pathology; **Dr. George E. Plum,** radiology; **Drs. Alexander Schirger** and **Dr. John W. Worthington, Jr.,** medicine, and **Dr. Robert J. Spencer,** proctology.

* * *

Dr. Samuel N. Litman, a hard-working Duluth physician with a long record of community leadership, recently was named to Duluth's Hall of Fame. Dr. Litman was selected for Duluth's highest citizenship award primarily for his work with free baby clinics in West Duluth, the West End and downtown Duluth.

* * *

A Long Prairie physician, **Dr. M. E. Mosby,** was among 200 physicians attending a recent two-day medical meeting on arthritis and birth defects held in Chicago.

A recent participant in the National Rehabilitation Association's regional conference held in Des Moines, was **Dr. G. Keith Stillwell,** consulting physician in the section of physical medicine and rehabilitation at the Mayo Clinic and an active leader in rehabilitation in Minnesota. About 315 specialists attended the meetings. Main speaker was Joseph Hunt, Assistant Director of the U. S. Office of Vocational Rehabilitation.

* * *

Dr. S. W. Giere, Benson, has received an award for fifteen years of service as medical advisor to the local selective service board. The certificate is signed in the name of President Eisenhower by Louis B. Hershey, national selective service director. Dr. Giere was also awarded a lapel pin for his service.

* * *

Dr. Hamilton Montgomery, Senior Consultant in the Section of Dermatology at the Mayo Clinic, and an internationally recognized authority on the microscopic aspects of diseases of the skin, assumed early emeritus status recently. Dr. Montgomery retired from active practice to devote full-time attention to the preparation of a volume on the subject of dermatohistopathology, a project which has been under way for a number of years and a field in which his career in medicine in recent years has been largely centered.

* * *

Dr. Jerome Hilger and **Dr. Woodard Colby,** St. Paul, were among speakers at a recent meeting of the Ramsey County Medical Society and the St. Paul District Dental Society. Problems related to both dentistry and medicine were discussed.

* * *

An Ely physician, **Dr. Manfred Dobler,** was elected chief of staff of the medical staff of the Ely-Bloomenson Community Hospital at a recent meeting. Elected as assistant chief of staff was **Dr. Edward W. Ciriacy.** Re-elected to the position of secretary was **Dr. Robert Kundel.** Other doctors on the staff include **Dr. J. P. Grahek, Dr. Jan Sekanina,** Babbitt, and **Dr. T. P. Mollers,** Soudan.

* * *

Drs. L. A. Aaro, D. G. Decker, J. E. Faber, J. S. Hunter, Jr., R. A. Smith and **R. B. Wilson,** Mayo physicians, were among 2,000 physicians attending the recent three-day Seventh Annual Clinical Meeting of the American College of Obstetricians and Gynecologists. The six Mayo physicians participated in round table discussions during the meeting.

Dr. Morton Roan, Ellendale, is hospitalized at Abbott Hospital, Minneapolis, suffering with acute nephritis. He was stricken recently in Minneapolis and ordered to the hospital for treatment.

* * *

Dr. Giles A. Koelsche, a consultant in medicine at the Mayo Clinic and a specialist in allergies, was named president-elect of the American College of Allergists recently at the college's Fifteenth Annual Congress in San Francisco.

* * *

Temporary officers of the Eveleth-Fitzgerald Community Hospital were named at a meeting held recently. They include **Dr. Frank R. Kotchevar,** Eveleth, president and **Dr. John L. Bonner,** Virginia, secretary. Also attending the meeting were **Drs. David J. Richter, M. Thomas Summar, Raymond J. Chittum, Thomas J. Gerend, Richard Payne, George Ewens, John L. Bonner, J. A. Malmstrom, C. S. Blackmore, R. W. Anderson, Matthew Wier, Whitney Woodroff, Isaac Prlina, A. M. Antonow, Paul Reed,** and **Richard E. Student,** all of the East Range Clinic; **Drs. Joseph Callan, W. S. Neff, D. R. Nelimark** and **David A. Sher,** all of the Lenont-Peterson Clinic, and **Drs. Joffry, E. R. Addy,** and **C. E. Goodman.**

* * *

Dr. Owen H. Wangensteen, University Hospitals, was among four University doctors who have successfully used dime-store balloons for stopping stomach hemorrhaging. A report of this treatment recently appeared in an issue of the *Journal of the American Medical Association.*

Drs. R. P. Pearsall, Virginia; **W. C. Heiam,** Cook; **F. R. Kotchevar,** Eveleth; and **E. R. Addy,** Gilbert, were among five Minnesota doctors recently presented with certificates of appreciation and fifteen-year pins for their service to Selective Service. Col. Murley A. Reep, State Director of Selective Service for Minnesota presented the awards.

* * *

Recent participants in the Second International Symposium of the Myasthenia Gravis Foundation in Los Angeles were three Mayo Clinic staff men, **Drs. Edward H. Lambert, E. Douglas Rooke** and **Donald W. Mudler.**

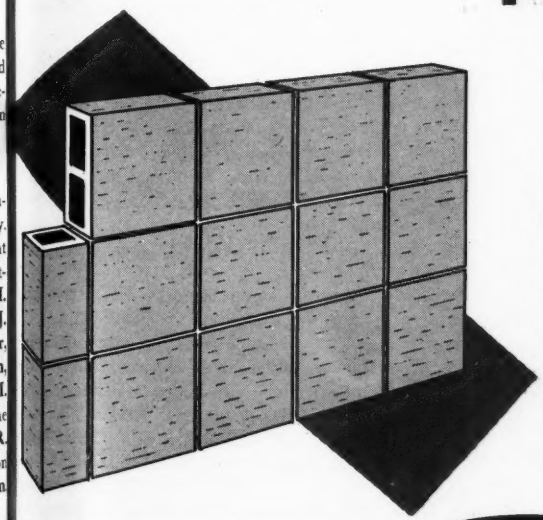
* * *

Dr. Robert G. Tinkham, Minneapolis, was elected Chief-of-Staff of St. Barnabas Hospital, Minneapolis, at the annual meeting of the Medical Staff. He succeeds **Dr. Edgar A. Webb.** Vice Chief-of-Staff is **Dr. Mancel T. Mitchell, Dr. Donald G. Bohn** was re-elected Secretary-Treasurer. Elected as Section Chiefs were: **Dr. Paul J. Bilka,** Medicine; **Dr. U. S. Anderson,** General Surgery; **Dr. John T. Moehn,** Obstetrics and Gynecology; **Dr. A. V. Stoesser,** Pediatrics; **Dr. N. H. Lufkin,** Pathology; **Dr. Archie M. Smith,** General Practice; **Dr. Carl J. Olson,** General Practice, and **Dr. Charles A. Aling,** General Practice.

Dr. C. Gordon Watson, Minneapolis, has become Chief of Staff of Fairview Hospital for the coming year. He succeeds **Dr. Harry B. Hall.** Named Chief-elect was **Dr. Lester W. Carlander, Jr.** Other medical officers are **Dr. George Martin,** secretary, and **Dr. Gordon W. Strom,** treasurer.

* * *

Four Mayo Clinic doctors participated in meetings of the International Academy of Pathology and the American Association of Pathologists and Bacteriologists at Boston recently. The doctors were **Dr. Jesse E. Edwards,** staff member of the Clinic's Section of Pathology; **Dr. Edith M. Parkhill,** consultant in Surgical Pathology at the Clinic; **Dr. Edward L. Segal,** a Fellow in Clinical Pathology, and **Dr. Grier F. Starr,** former member of the staff in Surgical Pathology, now in private practice in Eugene, Oregon.



* * *

Dr. B. Marden Black, Section of Surgery, Mayo Clinic, served as chairman of the committee in charge of Clinical Reviews, a three-day program for general practitioners of medicine offered each year by the Mayo Clinic. Assisting Dr. Black were **Dr. David T. Carr** and **Dr. Edwin D. Bayrd,** Section of Medicine; and **Dr. A. B. Hayles,** Section of Pediatrics.

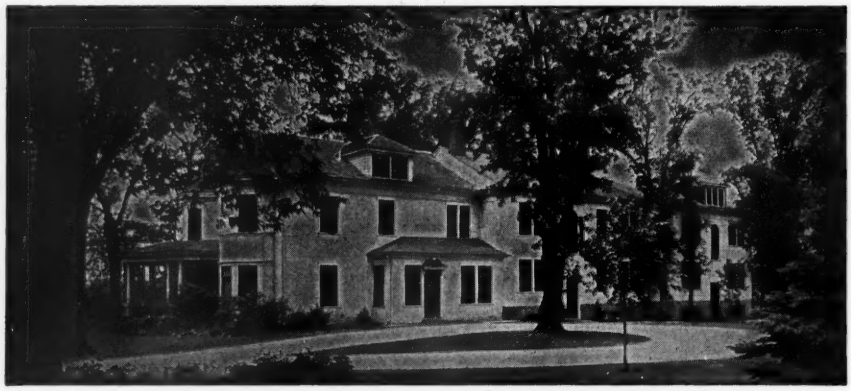
Ottumwa Brick and Tile Company Presents

BUFF VELOUR FACING TILE

A New Concept in Size, Color, Texture

This new Velour Facing Tile is ideal for exterior or interior walls, enabling your architect to achieve varied patterns and designs with a minimum of time and effort.

The unit, with its 8" x 8" modular face lends itself to the inserting of glazed or unglazed face brick in any type of pattern to produce an unlimited range of texture and color effects.



It's economical — no painting or finishing required. It's low in maintenance – can be washed easily. It has a high resistance to sound transmission and is extremely crack resistant. What's more, Buff Velour Facing Tile has a low first cost – the unit itself is low in cost and it can be laid in the wall quickly.

Ask your architect for more details or write direct.

4000 27th Avenue South PA. 9-6753

(467 pages, 340 illustrations, 231 figures, and 4 in color on 2 plates.) Philadelphia: Lea and Febiger, 1958. Price, $13.50.

This excellent work deals with the histogenesis, etiology, clinical manifestations, diagnosis, differential diagnosis, and therapy of virtually all tumors, benign or malignant of the lungs, pleura, and mediastinum. Many carefully chosen case histories with roentgen studies and photomicrographs of histological material illustrate both common and uncommon manifestations of tumors in the thoracic area.

Carcinoma of the lung is discussed in greatest detail, emphasis being placed on the early clinical manifestations of the disease. Two chapters devoted to the etiology of carcinoma of the lung are an excellent review and concise summary of recent experimental and clinical work.

There are separate chapters devoted to diagnostic procedures, radiology, pulmonary function, surgical treatment, and radiotherapy in connection with carcinoma of the lung which relate the uses and relative importance of these to the therapy of a given patient. Adenoma and rare tumors of the lungs and mediastinum, including tumors of lymphoid tissue, tumors of the thymus gland, terato-dermoids, neurogenic tumors and cysts are considered individually and completely.

Interesting historical references appear throughout this work and a well organized bibliography appears at the end of each chapter.

This comprehensive, well-written text of tumors of the lungs and mediastinum is recommended by this reviewer to all physicians—internists, as well as general practitioners, thoracic surgeons, chest specialists, and radiologists.

LLOYD D. MACLEAN, M.D.

THE PLASMA PROTEINS. CLINICAL SIGNIFICANCE. By Paul G. Weil, B.A., M.D.C.M., M.Sc., Ph.D. Director, Transfusion Service and Assistant Physician, Royal Victoria Hospital; Lecturer in Medicine, McGill University; Consultant in Medicine, Queen Mary Veterans and Grace Dart Hospitals; Consultant in Tranfusion, Queen Elizabeth and Royal Edward Laurentian Hospitals. 133 pages. Price, $3.50, cloth. Philadelphia: J. B. Lippincott Company, 1958, 1959.

This small monograph presents a brief, yet excellent review of plasma proteins as related to clinical practice. The author has satisfactorily succeeded in correlating the various abnormal states of the plasma proteins as reflected by diseases such as liver disease, neoplastic diseases, hemorrhagic disorders, metabolic derangements and auto-immuno hypersensitivity diseases.

A statement in the text that Bence Jones protein of the urine in multiple myeloma is probably the same as the abnormal globulin in the plasma is not in agreement with recent isotopic investigations. This fraction is a nitrogenous compound that is independently produced and the Bence Jones protein is unrelated to the circulating globulin of multiple myeloma.

This small text gives a brief review of the plasma proteins in normal and disease states. It is recommended to all students of medicine.

D. S. AMATUZIO, M.D.

Surgery of the Lymphatics in Cancer of the Rectum and Sigmoid Colon

LLOYD F. SHERMAN, M.D.
ROBERT J. TENNER, M.D.
Minneapolis, Minnesota

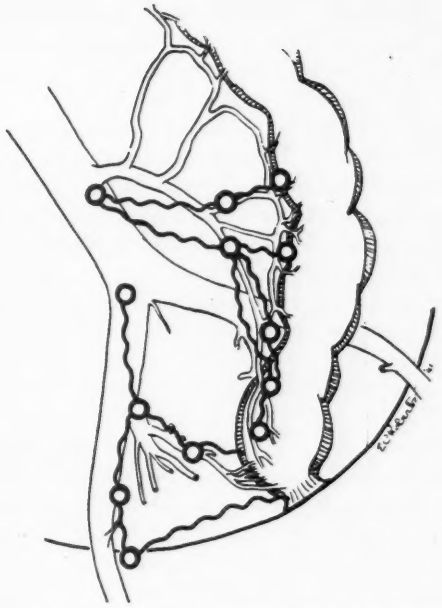

Fig. 1. Scheme of lymphatic drainage of the rectum and sigmoid colon.

Inaugural thesis presented by Lloyd F. Sherman, M.D., before the Minneapolis Surgical Society, May, 1958.

AS LONG AS surgery offers the only consistent method of curing cancer of the rectum and colon, those who assume that responsibility must be constantly on the alert for newer concepts to improve their survival rates. According to the Bureau of Vital Statistics, less than 30 per cent of the patients with rectal cancer operated in this country survive five or more years. This is hard to believe when some clinics report over 60 per cent five-year survivals. Partial blame for this low national survival figure, I am sure, is due to the patient's reluctance to seek earlier medical care, plus the lack of complete examinations once the care is sought. The greatest deterrent to increased survivals, however, is the reluctance of many operating surgeons to extend their lymph node dissections to cover all the possible avenues of lymphatic metastases.

During the past decade, a truly great contribution toward improved technique of cancer extirpation has been made by several workers (Fisher and Turnbull,[1] Pomeranz and Garlock,[2] Lloyd-Davies,[3] Abel,[4] Goligher[5] and Cole[6-8]) who formulated the concept of "cancer isolation." Extended resections can be of little value if these recently emphasized techniques of how cancer is approached and removed are disregarded.

Assumed that the operating surgeon is mindful of "cancer isolation" techniques, he may next gain more fruitful rewards by diverting his attentions toward the complete extirpation of all the possible avenues of lymphatic drainage of metastatic cancer of the involved segment of bowel. These have been described in the literature for the past fifty years, but little heeded until recently.[9] This is not a plea for ultraradical surgery, but rather a reminder that a thorough knowledge of the lymphatic drainage of the rectum and sigmoid colon is mandatory before one is qualified to select the most effective operation for cancers at various levels of this portion of the colon; and particularly since approximately 60 per cent of the patients presenting themselves for surgery, according to Coller, Kay and McIntyre,[10] Gilchrist and David,[11,12] Grinnell and Hiatt,[13] already have lymph node metastases (Fig. 1).

Moynihan,[14] in 1908, made the significant and often-quoted statement that, "Surgery of malignant disease is not a surgery of organs; it is the anatomy of the lymphatic system." Nowhere is this more applicable than to malignant disease of the rectum and colon. Since the introduction of the classical abdomenoperineal excision by Miles[15] in 1908, this operation has become established in many countries as (1) the standard operative procedure for removing rectal cancer and (2) the standard by which all other operative procedures are judged. However, one must not forget that the Miles procedure was introduced as a more adequate operation than the existing perineal-sacral methods of excision. It was indeed a more adequate operation, but in the same year (1908) Moynihan presented evidence that the lymphatic metastases which may be present at the aortic origin of the inferior mesenteric artery would not be removed by the Miles technique. This challenge to the adequacy of the Miles technique has remained unheeded until recently.

The original investigations of Miles[15] described three directions or avenues of lymphatic spread of cancer of the rectum and distal sigmoid colon, namely, the upward or superior avenue of metastases along the course of the superior hemorrhoidal vessels, the lateral avenue of spread eventually terminating in the iliac lymphatics, and the downward or retrograde avenue of spread below the level of the tumor.

It is the purpose of this paper to report several variations from the original investigative work of Miles,[15] that are documented in the recent literature and to report our observations in the lymphatic spread of rectal and sigmoid cancer which can be demonstrated with the *in vivo* injections of a vital dye* (Fig. 2).

The Superior Zone of Spread.—This represents the most frequent avenue of lymphatic metastases for cancer of the rectum and distal sigmoid colon. The superior lymphatic area of the rectum comprises those tissues containing the lymphatic channels and nodes which follow the superior hemorrhoidal vessels forming the superior pedicle of the rectum. The channels of this pedicle are most frequently satellites of the arteries and usually comprise two lymphatic channels for each artery. After perforating the muscular coat of the rectum, these lymphatics run upward and backward to reach the glands of the mesorectum. They traverse the pararectal nodes of Gerota, which vary from four to seven, are placed on the muscular layer and are covered by the fibrous coat of the rectum. They are encountered especially above the region of the ampulla and the lowest of them is situated immediately above the *Levators ani.* Glands of very minute size, unless some pathologic reason for their enlargement is present, are encountered along the superior hemorrhoidal vessels above the area described. In the mesosigmoid, above the minute glands, other glands of considerable size are grouped around the trunk of the superior hemorrhoidal artery.

Gerota,[16] and Poirier, Cuneo and Delamere[17] demonstrated that the rectum is divided into two distinct networks of lymphatic origin. Gerota differentiated a superior and an inferior lymphatic region in the rectum. The superior is composed of a close network of lymphatics and the inferior is made up of longitudinal bands of lymphatics disposed in a columnar form along the columns of Morgagni, representing the upper limits of that area (Fig. 3).

A more convincing demonstration that the rectum is divided into two different areas was made by Villemin, Huard and Montagné.[18] From this illustration (Fig. 3) it becomes clear that the rectum is divided into two different areas of spread, one below and the other above the middle valve of Houston (Kohlrasch's Plica). The upper rectum is drained exclusively through the superior pedicle while the lower portion of the rectum is drained by all three pedicles.

Villemin, Huard and Montagné described three different groups of nodes of the mesorectum:

1. One group is located at the bifurcation of the superior hemorrhoidal artery. These nodes received many short channels from the rectum and anus and are called the rectal group. These are the most important and common group of nodes of the rectum and for that reason Mondor called this area the hilus of the rectum.

2. Another group of nodes is found at the junction of the sigmoidal arteries with the superior hemorrhoidal. They receive the channels from the rectum and sigmoid and are called the rectosigmoidal group. These channels are usually the continuation of the channels of the previous group

*Injectable Sky Blue with Hyaluronidase-Wyeth.

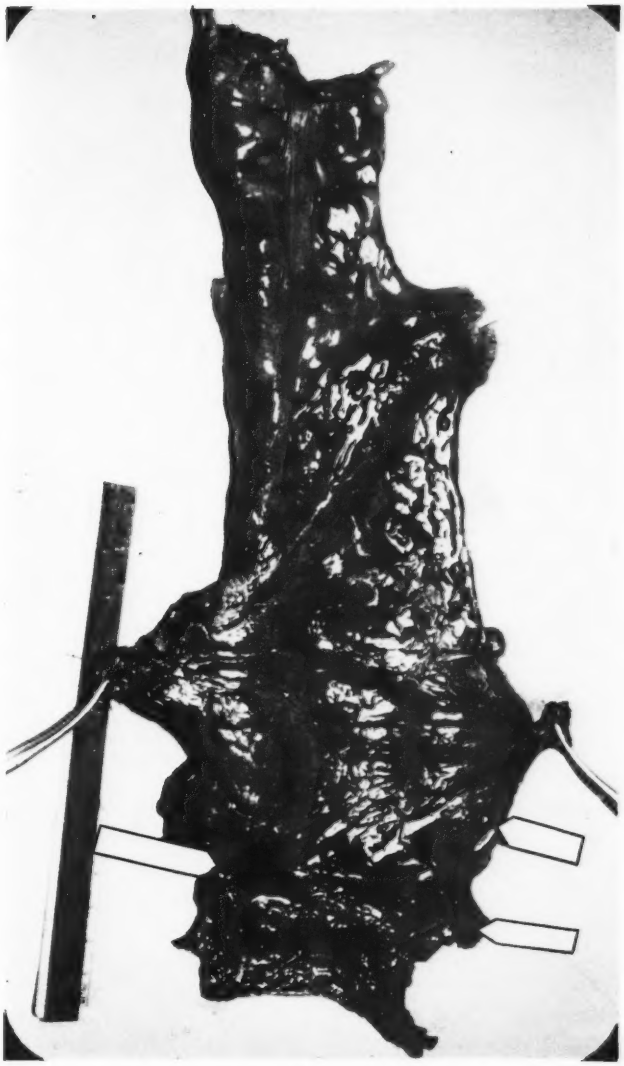

Fig. 2. Serosal view of sigmoid colon and rectum: Direct Sky Blue dye, 4 per cent, with hyaluronidase (Wyeth) was injected submucosally below an annular lesion at 5 centimeters. The dye has spread in all three directions of lymphatic drainage: superiorly, laterally and retrograde. (Lower arrow points to retracted stumps of levator muscle, upper right hand arrow points to a stained lymph node in the lateral ligament, hemastats mark the lateral ligaments, the avenues of lateral lymphatic spread of rectal cancer.)

though in some instances some channels of medium length reach these nodes without traversing the anterior group.

3. A third group of nodes is located where the inferior mesenteric artery gives origin to the left colic artery and the first sigmoidal artery. This group is called rectosigmoidal colic because it receives the lymph from the rectum, sigmoid and descending colon. The channels connecting this group are derived from the previous group of channels but there may be some channels of great length extending directly from the rectum without traversing the other groups. These channels are called the long channels and they may be accounted for by a variation from the orderly pattern described by Gilchrist and David, which is the common pattern encountered in the evolution of metastases to the nodes. Indeed, cancer cells may be drained from the lower rectum directly to the upper group of nodes without traveling through the other groups. This makes it possible to explain why McVay,[19] Gabriel, Dukes and Bussey[20] encountered the orderly spread described by Gilchrist and David in most of their cases, though in a few instances, one or two involved nodes were present well above the nodes in the proximity of the tumor.

It is the current consensus that the superior zone of lymphatic spread should be ligated as high as possible in resecting rectal and sigmoid cancers. Moynihan[14] pointed this out in 1908, but it remained for Ault[21,22] and his associates in 1950, to alert us to the inadequacy of superior ligations.

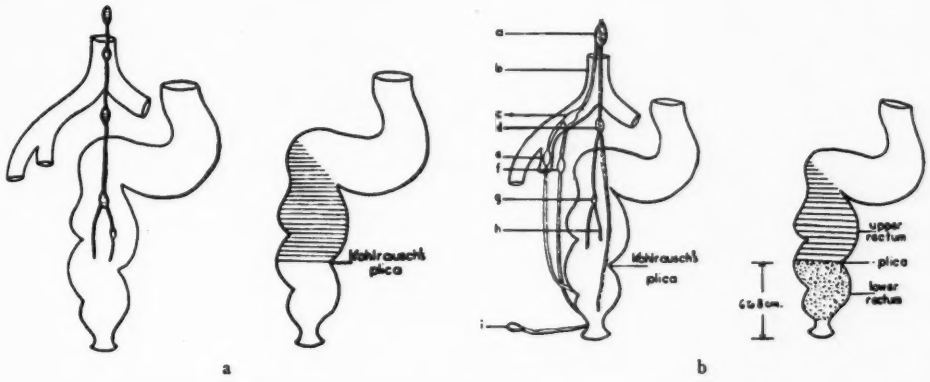

Fig. 3. *(a)* Injection of a blue dye above the plica of Kohlrausch. The lymphatic network of the upper rectum is colored by the dye and the lymphatics accompanying the superior hemorrhoidal veins are the only ones to become colored by the dye. (Modified from Villemin, Huard and Montagné: Rev. de Chir., 63:39, 1925.)

(b) A yellow dye was injected into the rectum below the plica and a blue one above. It is clearly shown that the rectum has two distinct lymphatic networks and that the plica is the limit between them. The inferior and lateral trunks drain only the lower rectum while the superior pedicle drains the upper and lower rectum. (Modified from Villemin, Huard and Montagné: Rev. de Chir., 63:39, 1925.)

They presented evidence that an additional two inches or more of gland-bearing vascular lymphatic tissue could be removed with a specimen of left colon or rectal cancer if extirpation of the inferior mesenteric artery was done at its aortic origin instead of removing it at the level of ligation suggested by Miles. Apparently fear of "Sudek's Critical Point" has deterred many surgeons from a more radical interruption of the superior zone of spread prior to this report. Ault[22] pointed out that Sudek was concerned with the perineal removal of the rectum in that his precautions are in no way valid as concerns the intra-abdominal ligation of the mesosigmoid with an abdominoperineal or anterior resection and that the whole false entity should be forgotten.

Extended dissections with high ligation of the inferior mesenteric artery have demonstrated that the instance of cancerous intramesenteric lymph nodes, located between the aortic origin of the inferior mesenteric artery and the Miles level of ligation may exceed 15 per cent. Grinnell and Hiatt[13] reported an instance of 17 per cent in 1952. Rossi[23] demonstrated positive nodes in 14 to 22 per cent of patients in 1954. McElwain and Ba-

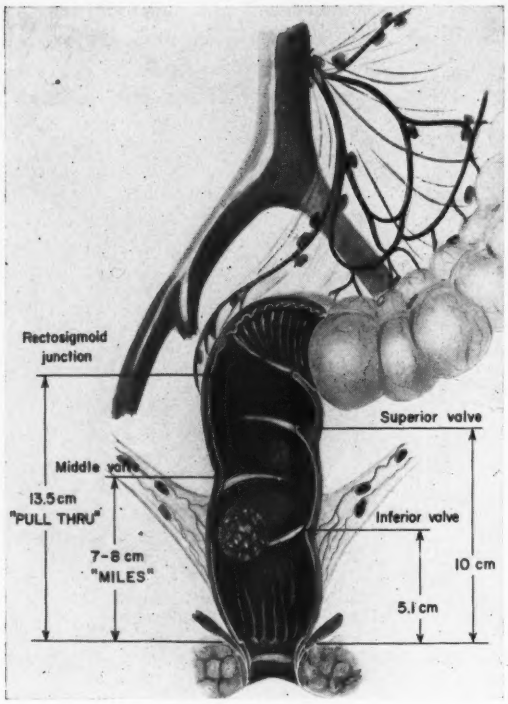

Fig. 4. Lymphatic drainage of rectum and sigmoid colon (L. F. Sherman).

con[24] reported 17.8 per cent of ninety patients to have had positive inferior mesenteric nodes at the time of resection (Fig. 4).

The Lateral Zone of Spread.—The lateral or middle area of the rectum has three main pedicles: A posterior, the lateral and the anterior.

The Posterior Pedicle: The efferents of this pedicle accompany the lateral or middle sacral vessels. The middle sacral channels cross one or more nodes. Because of their location they are called the nodes of the promontory. The lateral sacral nodes generally are located between the common iliac and the sacrum just below the origin of the internal iliac artery.

The Lateral Pedicle: This pedicle is formed by the lymphatics which follow the middle hemorrhoidal artery. These efferents constitute the most important pathway for metastasis to the lateral area of spread and are second only in importance to the superior pedicle for the drainage of the entire rectum.

The importance of these lymphatics has been underestimated owing to the fact that all emphasis was placed on the excision of the levators as the approach for the excision of these channels. The lateral lymph channels and nodes are contained in the lateral rectal stalks, some distance above the levators. The levators contain muscular lymphatics of local importance but cannot be considered as the site of the lateral lymphatic drainage of the rectum, as was originally postulated by Miles.[15] This is well substantiated by the work of Wood and Wilkie,[25] of Dukes[26] and of Guernsey, Waugh and Dockerty,[27] who showed the levators not as a site for lateral metastases but rather subject to direct tumor extension.

Sauer and Bacon[28,29] have recently stimulated our thinking in regard to the lateral zone of spread of cancer of the distal rectum by the use of vital dyes injected, *in vivo,* preoperatively. They were able to demonstrate that dye injected below Kohlrausch's plica (middle valve of Houston) stained the lymph nodes of the lateral pedicles but dye injected above this level was picked up by only the nodes of the superior pedicle. They further emphasized that the zone of lateral lymphatic spread was confined to the lateral rectal stalk some distance proximal and lateral to the levators and the most radical excision of the levators would in no way suffice to eradicate these tissues. Sauer and Bacon reported thirty-two complementary pelvic lymph node dissections for rectal cancers. Ten lesions located above the middle valve of Houston had no evidence of lateral spread. Twenty-two cases where the lesion was located below the middle valve of Houston and of these, six had metastatic nodes along the lateral zone of spread. They recommended complementary pelvic lymph node dissections, in addition to abdominoperineal resection for cancers below the middle valve of Houston.

During the past eight years we have engaged in similar studies to convince ourselves of the true nature and instance of the lateral lymphatic spread of cancer of the distal rectum. A vital dye (Injectable Sky-Blue with Hyaluronidase-Wyeth) was injected preoperatively in thirty patients. One-half of one cubic centimeter was injected submucosally just proximal to the pectinate line in four wheels above the anal mucosa. The dye at the time of surgery was found to stain the nodes of the superior, as well as the lateral pedicles, when it was injected below the middle valve of Houston. Thirty patients were submitted to pelvic

lymph node dissections and six (20 per cent) were found to have positive lymph nodes along the course of lateral spread. One patient had metastasis involving an obturator lymph node.

The most thorough and convincing study to appear in the literature in regard to the lateral zone of spread of rectal cancer was recently published by Freidin[30] of Australia. He testified that low rectal lesions have a poorer prognosis than those located above the middle valve of Houston due to the opportunity for additional direction of spread laterally, and he felt that this was the chief factor in the poorer prognosis.

Freidin[30] performed painstaking postoperative dissections on 100 cancers of the rectum produced by abdominoperineal resections. He ascertained that the superior and lateral vessels were two separate entities with no communication. The lymph channels and nodes accompanied these sets of vessels. In a number of specimens no lateral vessels could be found on either one or both sides although the lateral ligament was well developed or readily identifiable. Thirty-eight of the 100 dissections had no lateral vessels and accompanying lymph nodes. In these cases, the superior hemorrhoidal artery and veins completely replaced the lateral vessels by lower implantations on the rectal wall. This observation was correlated with the lack of bleeding from the cut ends of the lateral ligaments during surgery (Fig. 5).

No constant relation in level was found between the site of entry of the lateral vessels on one hand and the situation of the levators and the peritoneal reflection on the other. In other words, these three levels are independent entities, so that subdivision of neoplasms into supra and infraperitoneal groups or into groups dependent on the proximity of the tumor to the levators is, in either case, a fallacious concept since such subdivision may not coincide with the lateral fields. When lateral vessels were found, they occurred in more constant position than the peritoneal reflection; their level ranged from four to eight centimeters above the anal margin (Fig. 6).

The level of the peritoneal reflection varied greatly in this series. Taking the point of the anterior reflection, it ranged from 5 to 12 centimeters above the anal margin. Taking the lateral point of reflection on the right and the left lateral aspects of the rectal wall it ranged from 6 to 14 centimeters above the anal margin.

Freidin's[30] specimens were divided into three groups according to their level in relation to the lateral vessel field of spread:

1. Thirteen tumors are below the lateral fields.

Fig. 5. The superior and lateral rectal vessels are displayed (a black background has been introduced between the vessels and rectal wall). Note lymph nodes related to the right lateral vessels (Freidin).

Five showed lateral vessels and two had related lymph nodes involved by neoplasm.

2. Forty-eight tumors are situated at the lateral field level with lateral vessels in thirty-four, lymph nodes related to them in eighteen, ten of which were involved by neoplasm. In these two groups, lateral spread is shown to occur despite a superior avenue of spread which is either free of metastases

or contains only a small number of them. This contradicts the opinion expressed by all authors that lateral spread occurs only when the superior zone is blocked by metastases.

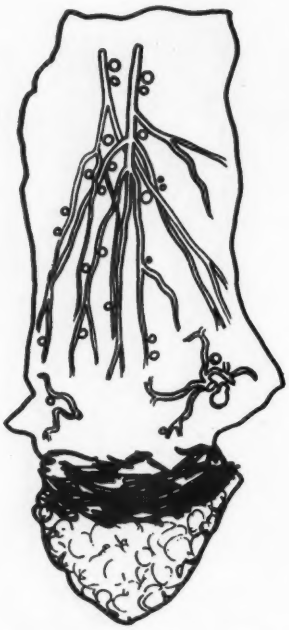

Fig. 6. Drawing showing the distribution of superior and lateral vessels of specimen shown in Figure 5 with the lymph nodes related to these vessels (Freidin).

3. In the third group of tumors situated above the lateral fields, twenty-three out of twenty-nine show lateral vessels, but only four had related lymph nodes, none of which is affected by malignancy.

The Anterior Pedicle: This pedicle is made up of two main groups of trunks, one on each side of the rectum. After leaving the rectum, it followed the rectourethralis muscle in an upward direction between the two layers of the rectogenital septum without perforating it. This septum (the rectovaginal in the female and Denonvillier's fascia in the male) is, according to Reinhold,[31] a barrier to the lymphatic penetration of the bladder, uterus and prostate. After reaching the rectogenital septum, the trunks turn upward until they reach the upper border of that fascia. They then deflect laterally, one on each side, and are directed toward the internal iliacs. Occasionally they fuse with the middle hemorrhoidal channels or with the lateral sacral trunks while in a few instances they connect with the external iliacs.

The superior and lateral zones of spread are by all means the most important avenues of metastases. They have and should receive the greatest considerations. Except for anterior and anterolateral cancers of the distal rectum in the female. Here there is great interchange of lymphatic drainage with the rectovaginal septum; making the excision of the posterior vaginal wall and uterus an indicated necessity where the cancers are situated in proximity. In the male, direct extension to involve the prostate or lymphatic invasion is a rarity.

Retograde Zone of Spread.—The literature is replete with evidence denying the probabilities of significant retrograde spread of cancer of the upper and mid-rectum. Glover and Waugh[32] presented convincing evidence that downward spread of rectal cancer occurred in no more than 1 per cent of the formalized specimens that they cleared, sectioned and measured. McVay,[19] Gabriel, Dukes and Bussey[20] and Grinnell[13] also showed that the retrograde spread of rectal cancer was much less extensive than reported by Miles, Gilchrist and David.[11,12,15] These investigators reported only one case with retrograde spread as far as 4 centimeters below the lesion.

In view of this overwhelming evidence against retrograde spread of rectal and rectosigmoid cancer, it would seem that one should be content to accept the available evidence and avoid further conjecture. That being the case, it would be difficult to explain the high incidence of recurrence following anterior resections for advanced cancers of the mid and upper rectum. Some clinics[33] have reported as high as 25 per cent recurrence following anterior resection for large lesions (presuming lymph node metastases) of the mid and upper rectum. Many surgeons[1,29] confess that they now limit their usage of anterior resection to early lesions (presuming negative lymph nodes) of the upper rectum and rectosigmoid, because of their high recurrence rates.

It is admitted that a certain number of recurrences following anterior resection can be blamed onto "seeding" of the anastomosis, coincident with manipulation of the lesion, and particularly since these lesions are more difficult to isolate than cancers higher in the colon. In 1951 Goligher[5]

and associates reported 10 per cent incidence of suture line implantation that occurred in sixteen of 152 patients who had sphincter-saving operations performed for cancer of the rectum and rectosigmoid.

Cole[7,8] similarly reported 10 per cent suture line recurrences in fifty-five patients. But with careful observation of "isolation technique" this percentage should be reduced to nil, yet, I am sure that a fairly high incidence of recurrence will prevail when advanced (Dukes "C") lesions of the mid and upper rectum are extirpated by anterior resections, and largely because lymph nodes involved with retrograde lymphatic metastases are left behind.

Two salient facts serve to convince us that retrograde metastases can occur more than as inconsequential rarities:

1. Vital dye can be forced retrograde to stain Gerota's nodes and nodes of the retrorectal lymphatic pedicle by obstructing its superior flow. Example: Specimens were obtained by two team synchronous abdominoperineal resections. The abdominal operator clamps the distal sigmoid and its mesentery; the perineal operator injects Direct Sky Blue dye, 4 per cent, with hyaluronidase *via* a proctoscope and a long tonsil needle submucosally just distal to the clamped bowel. Within fifteen minutes, the retrorectal pedicle and its nodes are stained in a retrograde fashion for a distance of 8 to 10 centimeters.

2. Postoperative dissections of fresh, non-formalized specimens have demonstrated several (six) with lymph nodes involved with cancer 6 to 8 centimeters below the lesions. All specimens have had superior node metastases, but they were not necessarily choked with metastases as has been suggested as a requisite.[32] All six patients were operable. A lymph-node cleaning project on fresh postoperative specimens is underway at this time, by the authors, in an attempt to either prove or disprove this thesis. Until that time, we will continue to resect lesions between the middle valve of Houston and 12 to 13 centimeters from the anal verge by "Pull-Thru" techniques, unless there is evidence of fixation and local extension.

Conclusions

1. A revived interest in the lymphatic drainage of the rectum and sigmoid colon is manifest in the literature during the past decade.

2. The superior zone of spread of cancer of the distal colon is the most frequently traversed by metastases. High inferior mesenteric artery ligation is mandatory. "Sudek's point" is now considered a myth. The rectum is divided into two distinct networks of lymphatic origin.

3. The importance of the lateral zone of spread has been underestimated because of misunderstanding of its anatomical location and consequent lack of excision even with wide removal of the levators. Studies using Direct Sky Blue dye demonstrate its course. Lateral spread occurs only with cancers located below the middle valve of Houston (Kohlrausch's plica). The closer the lesion to the lateral vessels, the more frequent the lateral metastases. Lateral spread may occur without superior blockage.

The peritoneal reflection is variable and is an inaccurate standard of measuring lesions. Operative procedures should be ascertained by the proctoscopic level of the lesion plus the usual criteria of operability.

4. The retrograde spread of rectal and sigmoid cancer is a reality, according to the authors. It usually occurs with superior blockage of lymphatic drainage and frequently enough to consider the resection of the entire rectum with its retrorectal lymphatic pedicle for lesions below 12 and 13 centimeters by either a Miles or "Pull-Thru" type of resection.

Postsurgical Fluid Balance

The author presents a correlation between the basic physiologic considerations of body water and electrolytes and the clinical management of the postsurgical patient. "W.A.S. triad" (weakness, anorexia, and silent abdomen) accompanies potassium deficiency in the body. Of all electrolyte replacement therapy, that which we employ for potassium deficiencies must be most carefully managed.

PHILIP THOREK, M.D.
Chicago, Illinois

Presented at the clinical session of the American Medical Association, Minneapolis, December 4, 1958.

THE BODY maintains an amazingly constant internal environment; this is known as homeostasis. To stabilize such uniformity of the fluid matrix of the body, the patient must be supplied with proper amounts of water, electrolytes and proteins. Marine organisms require a specific salty environment (sea water) to carry on their numerous complex vital chemical processes. The chemical composition of the extracellular fluid of man is practically the same as its sea-water prototype. In other words, man's oceanic environment is now internal instead of external. Numerous works have been written on this subject; however, some disagreement exists as to the type of solution and the exact amount of water and electrolytes necessary for the maintenance of homeostasis. Every postoperative patient must be supplied with adequate amounts of water, salt, proteins, carbohydrates and vitamins. Fats are still under investigation but may be available soon in a form safe for parenteral administration. Fats are rarely essential in the immediate postoperative care of the patient. Osmotic pressure of intracellular and extracellular body fluids is maintained by the shift of water and electrolytes across cell membranes. The chief cation of intracellular fluids is potassium, that of extracellular fluid is sodium. The kidneys play an all-important role in maintaining fluids and electrolytes at constant levels.

Water

This substance makes up about 70 per cent of the total body weight in the average normal adult. About 80 per cent of the body fluid is found in the cells, and the rest is extracellular (interstitial spaces and blood vessels). In obese patients the total body water may be less than 40 per cent; hence, such individuals do not tolerate fluid imbalance well. It is important to have a simple method of determining the patient's water needs and water balance. Usually this can be determined easily and quite accurately by utilizing the rule that the average patient must be given enough water to permit him to urinate between 750 and 1,000 cc. per day. Some authorities prefer to calculate the water and electrolyte needs by determining the number of milliliters necessary per meter of body surface. Body surface area determinations are made from the so-called nomogram, using height and weight. Numerous factors, such as excessive perspiration, diarrhea, respiratory rate, drains, fistulas and nasogastric siphonage, alter the urinary output and water needs; these require individual correction.

It has been stated that the daily amount of water ingested in food is approximately 1,500 cc. An additional 5,500 cc. of water or potential water enters the esophagogastric-intestinal tract per twenty-four hours as: saliva 500 cc., gastric juice

1,200 cc., bile 600 cc., pancreatic juice 1,200 cc. and succus entericus 2,000 cc. This constitutes a total of 8,000 cc., which is 11 per cent of the body weight and over half of the extracellular water. Not all of this is present in the gastrointestinal tract at a given time. Water absorption most likely begins in the upper small bowel and continues to and through the right half of the colon; normally, only 200 cc. in excreted in the feces. It is dangerous to state unequivocally that every postoperative patient must have three quarts of fluid per day or continuous intravenous drip. The average patient will urinate approximately 750 cc. of urine daily if 2,000 cc. of water is supplied. These rules do not pertain to the nephritic or the cardiac patient. If the physician wishes to determine rapidly the state of hydration of a given patient, he may test the specific gravity of the urine. Another method is to catheterize the patient and determine the amount of urine he puts out in one minute. A properly hydrated patient will void ten drops of urine per minute. Clinical signs of dehydration should be detected easily. They are thirst, dryness of the tongue, sunken eyeballs and the loss of tissue turgor.

Primary Water Depletion

In primary water depletion (esophageal obstruction, coma, et cetera), the extracellular fluid becomes hypertonic, causing water to move from the cell to the extracellular space. Although the resulting intracellular dehydration may be marked, there may be no change in plasma volume or electrolyte concentration. Therefore, in this condition there is a small urinary output and normal or increased concentration of plasma, protein and/or electrolytes. The treatment of primary water loss consists of water replacement. This is accomplished best by the administration of adequate amounts of 5 per cent dextrose in water. Since relatively small amounts of salt have been lost, hypotonic saline or amino acid solutions containing a little sodium chloride are most desirable. The average postoperative patient requires 1 liter of water to replace insensible loss (breathing and sweating) plus 1 liter for urinary output. Approximately 4 gm. (69 mEq.) of sodium chloride will usually replace the daily salt. Less salt and water are required the first twenty-four postoperative hours because of the stress response to surgery.

Sodium Chloride

Sodium chloride (salt) requirements of the average individual range between 4 and 12 gm. (69 to 208 mEq.) daily. Such requirements are altered by weather, heat, fever, suction, vomiting and fistulas, to mention only a few conditions. The terms "normal saline" or "physiologic solution of sodium chloride" refer to a 0.9 per cent solution. Such a solution is actually unphysiologic; hence, it should be referred to as an isotonic solution of sodium chloride.

An isotonic solution of sodium chloride contains 154 mEq. of sodium per liter. The sodium content of extracellular fluid is 142 mEq. per liter. Therefore, the sodium content of an isotonic solution of sodium chloride is 12 mEq. per liter greater than the sodium content of extracellular fluid. Although this may not be the ideal relationship, it is not harmful. The chloride content of extracellular fluid is 103 mEq. per liter as compared with 154 mEq. of chloride per liter of isotonic sodium chloride. This means an excess of 51 mEq. of chloride per liter of isotonic solution. Such a discrepancy places a load upon the kidneys which must maintain a constant electrolyte balance of the extracellular fluid. These 51 mEq. of excess chlorides and 12 mEq. of excess sodium per liter must be excreted. If the kidneys are impaired, such a load (particularly the chloride) may become serious or even lethal. Excesses of chloride may also disturb seriously the acid-base equilibrium of the body. There are 9 gm. of sodium chloride in each liter of isotonic salt solution. The administration of 2 or 3 such liters daily places 18 or 27 gm. of salt, respectively, into the body, results in tissue edema, dehiscence of suture lines, delay of healing and/or possibly death. However, if a patient is in negative sodium balance, then it may become necessary to administer more than 9 gm. It is at a time such as this that flame photometric readings and electrolyte determinations become necessary.

Primary Salt Depletion

Primary salt depletion is more common than primary water depletion. The most common causes are vomiting, gastric suction, intestinal obstruction, diarrhea and intestinal tract fistulas. In this condition the extracellular fluid becomes hypotonic. The kidneys attempt to combat this hypotonicity by excreting large amounts of urine and no salt;

the kidneys cannot retain water in the absence of salt; hence, further water depletion also occurs, even if large amounts are supplied. The plasma chloride concentration may remain normal until the kidneys can no longer excrete the extracellular water. Obliguria or anuria may precede the appearance of clinical shock. In primary salt depletion, the plasma reflects the changes in chloride or bicarbonate concentrations, depending upon which body fluid is lost. The loss of gastric juice produces a reduction of plasma chloride (normal 100 mEq.) and an elevation of bicarbonate ion concentration (above 30 mEq.). There may also be a small drop in plasma sodium. These patients develop alkalosis. When the loss is due to bile or pancreatic juice, there is a greater loss of sodium bicarbonate than sodium chloride. The plasma bicarbonate is reduced below 25 mEq. and there might be a slight increase in plasma chloride. These patients develop acidosis. The treatment for primary salt loss will vary accordingly to the source of such loss. In general, however, one may follow this plan:

1. Hypotonic salt solutions (0.45 per cent) should be used in the immediate postoperative period because of fluid and salt retention (steroid action).
2. Isotonic solutions of sodium chloride (0.9 per cent) as a general replacement should be used primarily when gastric juice is lost. It must be recalled that gastric juice is often hypotonic; hence, replacement of such drainage contents by the "volume for volume" rule is not always accurate; it requires re-evaluation if such loss is prolonged.
3. Hypertonic solutions of sodium chloride (2 to 5 per cent) are preferred in patients with pancreatic or intestinal fistulas because of the great salt loss. To attempt to compensate for such heavy salt losses with isotonic salt solutions would result in an excessive urinary output. Continuous and daily re-evaluation of these cases will determine the necessary requirements.

Potassium

This cation is chiefly intracellular. The exact daily requirement is not known; however, it has been estimated that the average adult requires from 2 to 4 gm. (51 to 102 mEq.). The primary causes of potassium deficiency include vomiting, diarrhea, pyloric obstruction, ulcerative colitis, intestinal fistulas, prolonged administration of ACTH or cortisone and continued usage of potassium-free solutions. Overproduction of ACTH endogenously may result from diabetic acidosis. Potassium deficit may also result from increased body utilization of potassium as occurs during the healing of burns. Clinical findings of this deficit are characterized by a triad which includes weakness, anorexia and silent abdomen, which the author calls the W.A.S. triad. If cells are deprived of potassium, they cannot function properly; this refers particularly to muscle cells (gastrointestinal and cardiac). When a patient is in negative potassium balance, the cells become depleted of this ion; sodium which exists mainly as an extracellular ion attempts to replace the lost potassium and becomes intracellular. Water follows the sodium into the cell with a resulting cellular edema. Swollen cells cannot function properly, this being particularly true of the mass of muscle cells. Hence, we find electrocardiographic changes and distended bowel. Palpable muscles feel soft and putty-like; and if the condition continues untreated, extreme weakness, tremors and coma result. Electrocardiographic findings of low voltage and flattening of the T waves are present when the potassium level is below 4 mEq. The plasma potassium may be normal or even increased in an early cellular potassium deficit; hence, the plasma level does not always reflect the true cellular potassium status. If alkalosis persists after adequate sodium chloride therapy and hydration, one must suspect a potassium deficit.

When sodium and potassium are being lost, the normal kidney conserves the sodium by almost total tubular reabsorption; the urine contains practically no sodium. Unfortunately, such a safety valve does not exist for the conservation of potassium. Even in conditions of severe potassium deficit this cation continues to be lost in the urine.

The treatment of potassium loss requires careful replacement. Since excessive potassium may produce a heart block and sudden death, it must be administered cautiously. It is usually contraindicated in cases of severe oliguria or anuria because of a potassium "pile-up." In emergency treatment from 4 to 5 gm. of potassium chloride should be given in 1 liter of 5 per cent dextrose and water. After this, 3 gm. of parenteral potassium chloride is usually necessary to maintain daily requirements. Oral administration of potassium chloride should be instituted as early as possible (5 to 10 gm.) daily for many days because the depletion is difficult to overcome. The reason for this is that the homeo-

static mechanism of the body attempts to prevent extracellular potassium from going above a level of 5.5 mEq. per liter.

Protein Requirements

The protein requirements for the average adult vary, depending upon the amount of physical energy expended, but have been calculated as being approximately 100 gm. per day. The protein needs of the desk worker are much less than those of the physical laborer. However, at bedrest, the average postoperative patient will not tear down his own proteins if we supply this minimum of 100 gm. per twenty-four hours. If the patient cannot take this per month, it must be supplied parenterally in blood, plasma, or one of the more modern solutions (hydrolasates) which supply the amino acids.

Carbohydrate Requirements

Carbohydrates also should be supplied in the amount of 100 gm. per day; again, this figure varies. This is administered in the form of 5 per cent dextrose. The diabetic patient must also have his proper daily allotment, but this must be covered with insulin. Such special cases should be managed by a physician well versed in diabetes.

Vitamins

Fat-soluble vitamins A and D usually are stored in the body, but the water-soluble vitamins B and C are depleted rapidly and require replacement. Vitamin B is necessary for the proper utilization of proteins; hence, it is advisable to give from two to three ampules of vitamin B complex per day. Vitamin C has been aptly referred to as the surgeon's vitamin, since it is essential for wound healing. If this vitamin is deficient, small petechial hemorrhages occur and interfere with proper healing. The author has found it advantageous to supply 1,500 mg. of cevitamic acid per day.

Some pharmaceutical houses, having become cognizant of these daily parenteral needs, now manufacture solutions which meet them. Each 1,000 cc. of such soltuion contains:

1. 1,000 cc. of water
2. Approximately 3 gm. of sodium chloride
3. 50 gm. of protein
4. 50 gm. of carbohydrate

To these, vitamins B and C and the necessary antimicrobials can be added. Each liter of such solutions contains half of the daily requirements. Therefore, it has been suggested that, following the patient's morning care, a liter of such solution be administered at the rate of one drop a second. This takes approximately three hours to give. Then the patient may be relieved of further intravenous therapy until the evening, when the second liter is given. In this way, the patient receives his daily requirements of water, 6 to 9 gm. of salt, 100 gm. of protein, 100 gm. of carbohydrates, and the necessary vitamins and medicaments. Let it be stressed again that in no instance should parenteral therapy be utilized if the patient can take fluid or food by mouth.

Nothing by mouth is an order that may be carried to an extreme. In cases of esophageal resection, the order is necessary for three days; in gastric resections, two days. Following this, the patient may have ice chips and sips of water (warm or cool). The next day—tea, dilute orange juice and fat-free broth are added. By the fifth to sixth day, semisolids are given; and at the end of the first week the patient is on a liberal soft diet. In patients not having anastomoses, tea and water are permitted *post nauseam*. Full liquids are given on the third day, and a regular light diet by the fifth to sixth day.

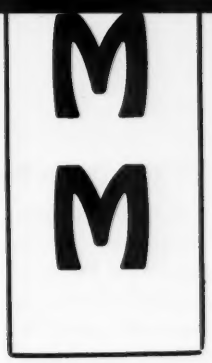
Selye had emphasized the importance of a stress or alarm action to such things as psychic trauma, anesthesia, exposure, surgical manipulation. The medulla of the adrenal gland, when stimulated by stress of trauma, produces epinephrine. This reaches the blood stream and is carried to the anterior lobe of the pituitary gland, which responds with a production of an adrenocorticotropic hormone (ACTH). This hormone is returned to the adrenal gland via the blood stream and stimulates the cortex of the gland, which responds with an outpouring of numerous steroids. Much remains unsolved regarding these steroids as to number and effects; however, the effects of a particular steroid on water and electrolyte balance have been studied extensively This steroid affects the kidney function in such a way that sodium and water are retained, and potassium is excreted. Therefore, it is preferable to withhold some water and sodium for the first twenty-four hours postoperatively and to supply and replenish the potassium loss. It has been the author's practice to supply, in the first twenty-four hours, 1,000 cc. of water in a 5 per cent dextrose solution to which 3 gm. of potassium chloride has been added. No sodium chloride is given during this first postoperative day unless there is a specific indication or depletion.

When To Do What in Children's Surgery

H. WILLIAM CLATWORTHY, JR., M.D.
Columbus, Ohio

Presented at the Clinical Session of the American Medical Association, Minneapolis, Minnesota, December 3, 1958.

AS A FIELD of special interest, children's surgery is not new. The first textbook on this broad subject was published in 1563 by Felix Wurtz, a Swiss surgeon, and dealt with the treatment of "the infirmities and defects of newborn children."[1] Interest in pediatric surgery has perhaps languished longer in the Dark Ages than most other surgical specialties, since prior to 1930 few surgeons made concentrated efforts to improve the lot of small patients except in a few isolated areas in the British Commonwealth, Scandinavia and this country. Fortunately, for children everywhere, there now appears to be a re-awakening of concern for the child and his technical surgical problems, his peculiar pathology, his physical, physiologic, and emotional limitations and to the prevention of unnecessary morbidity as well as mortality.



This renewed interest stems from demonstrated need for more fundamental work in this broad field. Recently, C. Marshall Lee, using records and facilities provided by The John Hancock Insurance Company, observed that one-quarter of all surgery (exclusive of that related to maternity and tonsillectomy and adnoidectomy) is currently being done in children under sixteen years of age. In a hospital survey, he also noted that children's hospitals and children's wards in general hospitals are rapidly becoming surgical centers since over one-half, 53.6 per cent, of 116,990 admissions surveyed were to the surgical services.[2] Surgical or semi-surgical maladies (congenital or acquired) are now the leading killers of our young; if one excludes prematurity, the first three causes of death are congenital defects, accidents and malignant disease.[3]

In considering the topic of "When to do What in Children's Surgery" one must include three types of patient problems: the neonatal surgical emergencies, the less urgent problems in older infants and children, and the strictly elective cases. In each instance the physician must balance the expected morbidity and mortality of the disease process if it is to be permitted to run its natural course against the risk of surgical intervention. For most patients three choices are available: today, tomorrow or never.

Neonatal Surgical Emergencies

Fortunately most malformed infants are not museums of congenital anomalies, but suffer from a single remediable defect. During the first few hours of the neonatal period, the major anomalies which are incompatible with continued existence can be corrected with most gratifying results, if the diagnosis has been established before the complications of the developmental malformations have further sapped the vitality of the patient, and if the treatment is initiated by skilled hands.

Obvious lesions such as omphalocele, meningocele, massive teratoma, imperforation of the anus are readily recognized. Similarly, the *early recognition of occult lesions* involving the respiratory and alimentary tract should also be a prime consideration of all professional personnel who attend

When to do what in children's surgery has no cookbook plan or timetable. The proper decision depends upon a clear understanding of the problem, correct and early diagnosis of the patient's condition, knowing the natural history of each disease process and treating children as children and not as little adults.

a laboring mother and her newborn child. The symptoms and signs of respiratory distress (tachypnea, dyspnea, cyanosis) or alimentary tract obstructions (hydramnios in the mother, excessive mucus, bilious vomiting, distention, failure to pass normal amounts of meconium) are, in general, equally clear if they are looked for. An accurate diagnosis can usually be reached quickly without any more complicated studies than normally carried out in any x-ray department (Table I and II).

TABLE I. RESPIRATORY DISTRESS IN NEWBORN INFANTS

If:	Tachypnea, dyspnea, or cyanosis are present
Do:	(1) Clear oropharynx
	(2) Aspirate stomach *via* nose
	(3) Order chest x-ray immediately
Remember: Oxygen is the only symptomatic therapy.	

In general, the younger the infant the less disturbing will be a major surgical procedure. The newborn infant has been living like a lord on the end of a cord; is well hydrated and hypervolemic; is in an excellent nutritional state; has high levels of circulating serum corticoids and inherited antibodies which enable him to adapt to stress and thwart infection. He possesses a high threshhold for pain and thus requires less toxic anesthetic agents; and if handled gently and skillfully, will tolerate major surgery extremely well and recover rapidly—or, if the need arises, he possesses the reserve to weather a prolonged convalescent period.

From three to fourteen days of age, the infant's abilities to withstand surgical stresses seem less effective. He is normally in a catabolic phase—losing weight, his adrenal response is sluggish, and

TABLE II. CONGENITAL ALIMENTARY TRACT OBSTRUCTION

If any *one* exists, suspect obstruction	
	(1) Mother has hydramnios
	(2) The child's abdomen is distended
	(3) Meconium is not evacuated
	(4) Vomitus bile-stained
Do:	Pass catheter into stomach
	X-ray abdomen and chest
	Use barium enema if obstruction is low
	Use lipiodol swallow *only* if obstruction is high and incomplete

it is probably desirable to avoid elective surgical procedures during this period. At the present time, the salvage rate in this small but important group of infants who require surgery during the first month of life is pitifully poor since in a sample area, studied by Rickham,[4] less than one-third of the curable infants survived (Table III).

TABLE III. INCIDENCE OF NEONATAL SURGICAL EMERGENCIES

Liverpool area population	2,113,350
Live births	41,127
Neonatal deaths	809
Congenital defects	133
Surgically curable	54
Cured	15

P. P. Rickham: *Lancet*, 262:332, 1952.

Less Urgent Problems in Older Patients

For the less urgent problems in children a few months or years of age, we must consider several additional factors in choosing the best time for surgical intervention. There remain many physicians who, because of local limitations, may choose to be "conservative" and let a child grow up until he is big enough to be operated upon like an adult. Actually, there is in truth little factual evidence to recommend such an approach particularly if the growing-up period is associated with the crippling morbidity and mortality of attrition.

For example, it has, as recently as 1956, been recommended that such a life-saving surgical procedure as the division of a patent ductus arteriosus be deferred until a child is six to twelve years of age unless he shows signs of heart failure. Yet, if one considers on the one hand the published operative results by age groups, the operative mortality is essentially the same (1.1 per cent under two years; 1.3 per cent, two to five years; 1.5 per cent, five to twelve years) regardless of age of the patient. While on the other hand, it is clear that persistent patency of the ductus arteriosus in an infant or child invites prolonged growth failure in many and for some there is the risk of premature death from such complications as endarteritis and progressive pulmonary vascular changes which may make corrective surgery impossible.[5] It is difficult to avoid concluding that the earlier the operation, the more normal lives will be saved.

The inguinal hernia is a more commonly encountered problem where a similar line of reasoning is applicable. For several years physicians in our area have been referring infants with congenital, indirect inguinal hernias for early, so-called radical surgery, as soon as the hernia is diagnosed. In retrospect, this appears to be a more conservative approach since there is little hope for permanent cure by expectant or truss treatment; since the mortality is nil and the morbidity slight; and the infant is spared running the gamut of such major complications as incarceration and strangulation which may be expected to occur in 10 to 15 per cent of these cases—particularly in the very young infant. Such a forthright approach to this very common developmental anomaly is gratifying to the patient, parents, and physician alike.[6]

By contrast, it seems wisest to be conservative when managing such a self-limited malady as the umbilical hernia which is so commonly observed (15 per cent of white and 25 per cent of colored infants) that it may indeed be considered normal. Furthermore, follow-up studies by Woods in Britain[7] and by Crump and Robinson[8,9] in our Southern states have clearly indicated that 80 per cent of all infantile umbilical hernias close spontaneously by two years of age and that more than 95 per cent will disappear by the time the child enters school.

These are but three examples of the manner by which a detailed knowledge of the *natural history* of the congenital defects should help us in choosing the time of election for surgical intervention.

Elective Surgery

Finally, there are some less tangible problems of less real importance than the disease process itself but which nonetheless deserve consideration in the practice of the art of children's surgery. Problems that we can *all* do something about in every institution in which care is provided for children. These are the nosocomial or hospital-acquired infections which plague the infants—and the emotional disturbances following elective surgery which leave more significant scars than the surgeon's knife on the psyche of the toddler and pre-school child (two to five years of age).

For Infants.—Every hospital facility which admits infants for surgical procedures should provide clean, isolation-type facilities to protect the immunologically immature infant not only from his medically sick neighbors but also from members of the hospital staff who so frequently are the asymptomatic carriers of organisms capable of producing disease in the young child. "Clean" surgical infants should not be mixed with infected or "dirty" infants and both need safe conduct through the heavily traveled areas of our institutions—the admitting office, and the x-ray and operating and recovery suites.

Unless such facilities are provided, it is reasonable to expect that the morbidity of hospital-acquired illness may exceed that of the anesthesia, operation and convalescence, combined.[10]

For Children.—Emotional trauma largely can be prevented by a co-operative amiable organized effort of all people who work with our younger children. During the summers of 1956 and 1957, a carefully conducted study of 104 children two to fifteen years of age was carried out at our hos-

pital to ascertain what could be done about the postoperative emotional disturbances which were obviously occurring in a significant number of these youngsters. Pre-hospitalization, in-hospital and post-hospital visits with the patient and the parents were conducted. It was found that 69 per cent of the children had a *good* adjustment to the hospital experience.

The remaining 31 per cent of the children suffered from significant emotional upsets following elective surgical procedures. Fortunately, only 6 per cent had serious prolonged regressive manifestations—fears, bed-wetting, anxiety and withdrawn behavior. Similar observations (26 per cent poor adjustment) have been reported by Jessner and Kaplan following tonsillectomy and adnoidectomy. Prugh reports 36 per cent similarly afflicted from hospitalization, alone. In all studies the most serious disturbances were most noted in the two and three-year-old children.[11,12]

In our study there seemed to be certain things that were particularly disturbing: induction of anesthesia (50 per cent), shots (45 per cent), separation from parents (33 per cent). Examinations and white coats bothered few. Fortunately, there were some things the youngsters liked about our hospital too: toy ladies (50 per cent), other children (30 per cent), nurses (20 per cent), snacks (15 per cent), and television (10 per cent).

A review of this material would lead us to the conclusion that the best way to avoid emotional disturbances in the child and probably the family is to *do as much elective surgery as possible in infancy—the earlier the better;* and to avoid elective hospitalization, particularly in those youngsters two to four years of age; to spend a brief period of time preparing the child and his family for the hospital experience; to use long-acting oral medications wherever possible; to have adequate play areas where pre-school children can get well together; allow frequent visiting; and, above all, to insist on adequate premedication before the induction of anesthesia (Table IV).

Emotional disturbances are not all limited to hospitalization. Correction of cosmetically important developmental aberrations, including being a well-balanced boy with two testicles instead of one; possessing a male urethra which shoots straight; or pinned-back ears if nature has been too generous; or removal of an ugly birthmark—all constitute psychologically sound surgery if done before the child enters the school environment.

TABLE IV. PREVENTION OF EMOTIONAL TRAUMA IN CHILDREN

Honest orientation of parent and child
Long-acting or oral medications
Frequent visits or rooming-in
Toy carts—play areas—television
Adequate premedication—sleep

Perform elective surgery in infants under two years of age. Avoid elective surgery in three to five-year age group.

In summary, there is no cookbook plan for what to do when. In a final analysis, like most things in medicine—the proper decision is dependent upon a clear understanding of the problem; the correct and early diagnosis of the patient; knowledge of the natural history of each disease process; recognition that children are fine surgical risks if they are treated logically *as children and not just little men and women.*

Chest Injuries from Automobile Accidents

Are you likely suddenly to face the responsibility of the emergency care of this magnitude?

THOMAS J. KINSELLA, M.D.
Minneapolis, Minnesota

This report was presented at the Clinical Session of the American Medical Association in Minneapolis on December 2, 1958.

THE AUTOMOBILE, our friend, servant or enemy depending upon your point of view, is the most frequent cause of the thoracic injuries which we encounter clinically. The relatively frail human form, whether it be driver, passenger or pedestrian, in competition with this speeding mass of steel and plastic, invariably comes out second best in the resulting crash. If the victim survives the original ordeal and reaches the hospital, he confronts the attending physician with serious surgical, physiologic, and mechanical problems.

Crushing or compression injuries constitute the vast majority of the injuries encountered, although occasionally a closed penetrating wound and, very rarely, an open penetrating type of wound is encountered. Any of the three types may be fatal and each presents its own particular hazards and complications.

The crushing or compression type of injury may occur in a variety of ways: (1) from direct crushing or compression of an individual who is pinned beneath the car or other object, or a child crushed under a larger individual, (2) deceleration type of compression injury from a head-on collision or a speeding car striking a relatively immovable object and forcefully throwing the driver against the steering post or a passenger against the instrument panel or the back of the front seat, or hurling an individual from a car to the ground or against some other object, (3) a direct blow to the chest or a pedestrian struck by a car fender and knocked to the ground or against some other object. All degrees of variation and extent may be encountered from a mere superficial contusion to fracture of one or more ribs to multiple fracture of all ribs, with rupture of anything within the thorax.

The chest is a peculiar structure and it is perfectly possible, at least in young individuals, to compress the chest in an anterior-posterior direction to such an extent that the sternum is practically in contact with the vertebral bodies without fracture of rib or cartilage. Then, with the release of pressure the chest wall and sternum may spring back to the original position leaving no external evidence of the compression except perhaps some contusion or abrasion of the skin. For this reason, the physician may fail to appreciate the seriousness of injury to the thoracic organs, or the possibility of such injury being present when a patient is first seen. Should rib fractures occur as a result of such a compression, they are most likely to occur in the midaxillary region with the spicules of broken rib directed outwards with little tendency to penetrate lung, pleura or the intercostal vessels. An oblique application of force may give fractures posteriorly on one side and anteriorly on the other side.

A compression of similar nature in an older individual may result in bilateral anterior rib fractures with or without costochondral or chondrosternal separations or fracture of cartilage. Such fractures, particularly anteriorly, may give rise to a great deal of abnormal chest wall motion, the so-called flail chest. Transverse fracture of the sternum may occur with or without much displacement, the tendency being for the upper fragment to over-ride the lower. Respiratory embarrassment and interference with cough and expectoration with retained or aspirated secretions or other material may follow with subsequent respiratory ambarrassment, atelectasis, pneumonitis or abscess formation.

Even without apparent gross damage to the thoracic cage, serious if not fatal damage to any of the important structures within the chest may result from such compression. Rupture of an auricle, ventricle, aorta, vena cava, pulmonary artery or vein, or azygos vein may occur and be fatal within a short period of time. Damage to coronary vessels or to the myocardium may result, and while not immediately fatal, it may be subse-

Dr. Kinsella is Clinical Professor of Surgery, University of Minnesota, Minneapolis, Minnesota.

quently, or it may give rise to serious handicaps. Rupture of the trachea or bronchus may occur and if not promptly recognized and relieved may give rise to serious or even fatal tension pnuemothorax. Rupture of the lung parenchyma, unilaterally or bilaterally, may produce extensive pneumothorax unilaterally or bilaterally which may go on to collapse with a fatal outcome.

Traumatic rupture of the bronchus or trachea usually occurs near the bifurcation or in one of the major bronchi. Occasionally the trachea is ruptured in the cervical region, a serious condition which must be recognized and treated promptly. If suspected, it can be proven easily by bronchoscopic visualization and immediate surgical repair by direct anastomosis carried out. A few patients with rupture of the bronchus may recover following decompression of tension pneumothorax, the ruptured bronchus healing with stricture formation and loss of function of the involved lobes.

Rupture of the diaphragm, more commonly on the left but occasionally on the right, with protrusion of abdominal viscera into the thoracic space may follow any crushing injury of chest or abdomen and seriously embarrass respiration and ventilation. Nasal suction to reduce distention of a herniated stomach or intestinal loop as well as to reduce the chance of incarceration and obstruction may be used to advantage to relieve respiratory distress. Following severe trauma to the chest or abdomen no patient should be discharged from observation until the integrity of the diaphragm has been demonstrated. Traumatic diaphragmatic hernias because of subsequent adhesions present greater danger of intestinal or colonic obstruction than other types of diaphragmatic protrusions.

Rupture of air vesicles within the lung with air leakage out along the vascular sheath of the great vessels into the mediastinum can give rise to serious compression of thin-walled structures with serious consequences if the mediastinum is not decompressed. If the dissecting air escapes to the fascial planes above, an extensive and distressing subcutaneous emphysema may follow, however, this is usually not fatal.

Rupture of the esophagus occurs rarely but may be followed by fatal mediastinal infection or more rarely by tracheo-esophageal fistula. Tearing of internal mammary or intercostal vessels or laceration of the lung may result in serious internal bleeding with hemothorax, even of an exsanguinating type. Weakening but not complete rupture of the aortic wall or the wall of other great vessels may result in an aneurysm later.

Intrapulmonary hematoma or mediastinal hematoma occasionally is encountered following traumatic injuries to the chest but usually, except for an occasional mediastinal hematoma with compression of the thin-walled veins, does not call for surgical intervention.

Laceration of the lung from tearing of the lung by rib splinters may give rise to extensive hemothorax, pneumothorax or subcutaneous emphysema, or all three, and may require early thoracotomy.

Because of the potential possibilities of chest injuries and our inability, when the patient is first examined, to accurately assess the seriousness of the original injury or the amount of damage which has been done, these patients should be hospitalized, thoroughly studied, and observed until the exact nature and extent of the injury can be determined. Blood studies including hemoglobin, white count, hematocrit and probably blood volume, should be recorded as a base line for comparison with future studies in order to determine the extent of blood loss. The patient should be cross-matched for transfusion without delay since emergency transfusions may become necessary. A routine electrocardiogram should be made because of the possibility of damage to the myocardium or coronary circulation and again as a comparison for subsequent cardiac studies. Good x-ray pictures of the chest should be made with detailed studies of ribs as indicated when the patient's condition will permit. The number, position and extent of rib fractures may not be determined on preliminary examination as the chest films on chest injury cases are often not particularly satisfactory because of poor technical quality or because the fracture sites are obscured by hemothorax or subcutaneous emphysema, imperfect position, overlapping structures, or lack of displacement at fracture sites. Physical examination with local crepitation or point tenderness over the fracture site may give a more accurate index of rib fracture than the x-ray films. Some rib fractures only become evident by callus formation at a subsequent date. The over-riding rib fragments following a direct blow heal with deformity and bony bridging between the affected ribs, giving fixation of the chest wall and reduc-

tion in respiratory chest wall motion. These patients are usually not in condition for surgical attempts to correct the deformity. The results of such attempts outside of traction are not too encouraging.

Closed penetrating injuries of the chest rarely occur in automobile accidents. They may occur from penetration of the chest by a splinter of glass or wood from a tree or guard rail, a projecting object from another car or truck, or some object on the roadside when the patient is thrown from the car, or in the case of a pedestrian, from a pointed radiator emblem or a projecting door handle on an older model car. The seriousness of such an injury depends on the size, nature and depth of penetration and the structure within the chest injured by it. It should be the rule if there is deep penetration that the penetrating object not be removed except at thoracotomy in the operating room with facilities immediately available for the control of serious bleeding which may follow the removal. More rarely we encounter a penetrating wound in which the chest is actually torn open widely enough so that a sucking chest wall results. These occur occasionally from the spoke of a broken steering wheel or some larger object penetrating the chest. These are extremely serious. The suction must be stopped at once by any means at hand, with surgical correction of the damage and the defect carried out promptly thereafter.

Primary consideration in the treatment of traumatic injuries of the chest involve three general points: (a) control of hemorrhage, (b) treatment of shock, (c) restoration of cardiac and respiratory physiology. While simply stated, these three points are not always easily accomplished.

The general regime of treatment of these patients includes the following:

1. *Avoidance of Injury in Moving.*—These patients should be handled as gently as a cracked egg. Any rough handling in lifting or turning in the presence of fractured ribs may aggravate the injury or initiate bleeding, tear the lung or pleura, and superimpose bleeding, pneumothorax or subcutaneous emphysema upon the already-traumatized patient. The same may also be said about over-enthusiastic efforts to strap or immobilize the chest wall, thereby overlapping rib fragments and aggravating the damage.

2. *Treatment of Shock.*—The amount of shock present in these patients will vary widely from little or none to a very marked shock state. It must be treated by appropriate measures. One must be doubly careful not to assume that a shock-like state is due entirely to trauma, but rather be sure it is not due to internal hemorrhage or to a tension pneumothorax, both of which require different treatment.

3. *Oxygen.*—Many patients need oxygen for relief of dyspnea and cyanosis and should receive it freely, if not routinely. It must be remembered, however, that while the use of oxygen may reduce respiratory effort, it will not overcome the deleterious effects of an unstable chest wall, the mechanical handicap of a tension pneumothorax, or the air hunger resulting from depletion of the circulating red cell mass by internal hemorrhage.

4. *Stabilization of the Chest.*—If, because of multiple rib or cartilage fractures or separations, the chest wall becomes unstable, paroxysmal breathing will occur with serious disturbance of both respiratory and circulatory physiology. A sucking chest wound must be closed immediately by packing, strapping or suture, or serious consequences will follow. An unstable chest wall permits inspiratory retraction and expiratory bulging which not only interferes with aeration of the lung and with the expulsion of secretions but also results in circulatory embarrassment by upsetting the normal intrapleural pressure relationships which are essential in cardiac input and output. The chest wall motion must be controlled or minimized by posture, application of external weights, strapping, adhesive binders or by skeletal traction on the sternum or ribs. If these measures are not immediately successful, tracheotomy by cutting down the respiratory dead space and reducing inspiratory effort will greatly reduce the false motion and can be life-saving. Assisted respiration by mechanical apparatus may also help.

5. *Hospitalization.*—These patients should be hospitalized immediately for study and observation, even though at the moment the injury appears to be not too serious. Careful physical examination should be made to determine if possible the extent of injury to the chest as well as to other portions of the body. The association of multiple fractures and trauma to the abdomen,

spine, neck, face and skull may seriously interfere with the treatment of the thoracic condition. Vital signs must be watched and blood pressure readings taken and recorded frequently and blood studies made as previously mentioned. The urine should be examined. An electrocardiogram should be made for immediate information as well as for future reference. X-ray studies should be made as extensively as the patient's condition will permit. If the patient is in shock, of course, the head-down position is mandatory to avoid cerebral anoxia. If not in shock, the patient will breathe better, feel better and do better in a semi-sitting position propped up on a back rest.

6. *Control of Pain.*—Some of these patients are in great pain because of multiple fractures. This pain is aggravated by the effort of breathing and coughing so it is essential that some relief be given. Control of pain may relieve a shock-like state. Morphine and its derivatives will relieve pain and apprehension, but are a two-edged sword in that they take away the desire to cough and thus favor retention of secretions locally formed or aspirated into the lung. They should therefore be used in reduced dosage that will not "knock the patient out." The patient must be encouraged to cough and raise sputum periodically in order to keep the air passages free of secretion. Intercostal nerve block proximal to the fracture sites will definitely relieve pain and enable the patient to cough more effectively. Care must be taken, however, to avoid injury to the lung by the anesthetic needle or an accidental pneumothorax may be superimposed on the existing injuries.

7. *Watch for Internal Bleeding.*—Internal bleeding occurs frequently in all types of chest injuries. Coagulation of blood does not occur readily in the pleural cavity so bleeding tends to continue insidiously. Any rapid accumulation of fluid in the chest following an injury is blood and not serum. If the physician will only realize that a patient can bleed to death into one pleural cavity and that 3,000 cc. of blood and fluid can accumulate in one pleural cavity without much displacement of the heart or mediastinum, he will become more alert to the dangers of this complication. It is very difficult to estimate with any degree of accuracy the amount of blood which has accumulated in the pleural cavity. Base-line studies of blood (previously mentioned) compared with studies at a subsequent time may give some idea of the loss. If the chest fills up quite rapidly, it usually indicates arterial bleeding or injury to a larger vessel which presents a greater indication for immediate surgical control.

Blood within the pleural cavity, if it is not mechanically embarrassing or sufficient to demand immediate surgical intervention, need not be immediately removed since the mass of the blood itself not infrequently tends to tamponade and control the bleeding. Blood in the pleural cavity tends to remain liquid for some time, particularly in the absence of extensive damage to chest wall muscle and lung which would furnish hemostatic substance. Early aspiration may tend to restart the bleeding. The blood should be removed, however, after two or three days in order to minimize clotting and subsequent loss of lung function. If clotting occurs and the residual hematoma exceeds 20 or 25 per cent of the volume of the one lung, decortication with removal of the hematoma should be undertaken. This may be done at any time up to ten or twelve weeks without too much difficulty. With less than this amount, the impairment from the retained blood after absorption will probably not reduce function any more than the limitation following thoracotomy.

8. *Transfusion as Necessary.* — Transfusion must be used to replace blood loss but must not be overdone as it is possible to push a patient into pulmonary edema. It is impossible by ordinary transfusion methods to keep ahead of the steady bleeding from an internal mammary or intercostal artery, to say nothing of that from a larger vessel. Rapid or continued internal bleeding calls for thoracotomy and surgical control of the bleeding if other conditions will permit such surgical intervention.

9. *Watch for Pneumothorax.*—Pneumothorax in varying degrees occurs frequently in all types of chest injury, and not a few patients die from an unrecognized pneumothorax. It may be small in amount and not particularly embarrassing to the patient, or a tension pneumothorax may develop unilaterally or bilaterally which will seriously threaten or jeopardize the patient's life. A tension pneumothorax is any pneumothorax in which the pressure builds up to the point where

it is embarrassing to the patient. If the physician will only think about the possibility of the condition, he can easily diagnose it on physical examination: the side will be splinted; the percussion note will be normal to hyper-resonant as compared to dullness or flatness associated with fluid; the breath sounds will be distant to absent—especially anteriorly when the patient is supine, whereas with fluid, the lung frequently floats up in a recumbent position with breath sounds present in front. The heart and mediastinum will be displaced to the opposite side if there is tension of any appreciable degree with disappearance of the substernal dullness, muffling of the heart tones at the base, and palpable displacement of the trachea in the suprasternal notch.

The relief of a tension pneumothorax requires no special apparatus. Frequently the insertion of a needle into a tension pocket will be followed by the plunger blowing out of the syringe by a rush of the escaping air which will continue until the excess pressure is relieved. The rule is that a tension pneumothorax tends to recur and consequently one must make provision for repeated decompression by inserting a small catheter in the second anterior interspace in the midclavicular line and connecting it to an under-water breakover so that any accumulating pressure will be dissipated through the water seal. The insertion of a catheter at the base posteriorly is proper for the removal of fluid but soon plugs with fibrin and does not remove the airpocket which forms anteriorly. If both fluid and air must be removed, two catheters should be used. A constant, negative pressure suction pump with very low negative pressure of 1 or 2 cm. of water may be substituted for the under-water breakover. Traumatic pneumothorax may occur bilaterally and must be promptly recognized and relieved or the patient may succumb rapidly. Pneumothorax may not be present when the patient is first seen but may develop insidiously hours afterwards or may develop dramatically after an episode of coughing or straining.

10. *Removal of Secretions.*—Following thoracic injuries, patients are embarrassed frequently by the accumulations of secretions in the tracheobronchial tree—aspirated material from postnasal mucous drainage, blood or secretions from injuries to the nose, face or mouth, or from aspirated gastric contents, as well as in the patient with bronchitis, bronchiectasis, or tuberculosis, and in the chronic smoker. Because of pain, instability of the chest wall with loss of cough effort, injudicious use of sedatives, or the drying effect of oxygen inhalation or mouth breathing, the inability to expel these secretions may become a serious problem. Respiratory exchange is impaired if secretions are not removed from the tracheo-bronchial tree, and atelectasis follows with increasing dyspnea, and subsequently pneumonitis, pneumonia or abscess may occur. It is the physician's duty to see that secretions are removed from the chest. If, by stabilization of the chest and control of pain, the patient is able to cough and raise, then nothing further is necessary.

Thinning of secretions by the use of expectorents, by adequate hydration of the patient or by the use of water vapor will facilitate bringing up these retained secretions. Support of the chest wall during a cough effort may aid expulsion of secretions. If they cannot be removed in this way, they should be aspirated through a catheter passed through the nose or directly through a laryngoscope after spraying the pharynx and larynx with a local anesthetic solution. The unconscious patient may have his tracheobronchial tree aspirated by a nasal catheter without anesthesia as often as necessary. An endotracheal tube may be used for short periods of time. Bronchoscopy and bronchial suction through this instrument are effective means of removing secretions but frequent repetition is not advisable. Tracheotomy which permits repeated suction of the tracheo-bronchial tree as often as is necessary, can well be a life-saving measure for these patients.

10. *Chemotherapy.*—Patients with chest injuries must be treated adequately with antibiotics —particularly if there has been a recent respiratory infection, if bronchitis or bronchiectasis was present, or if the patient aspirated blood, stomach contents or other material at the time of or subsequent to the accident—in order to minimize the chances of pneumonitis or pulmonary abscess.

Conclusion

Trauma to the chest from automobile accidents is a common and usually very serious type of injury. Many things may be done to afford relief to these patients. Many of them present serious situations which will tax the ingenuity of everyone concerned in their treatment.

Urinary Diversion: Uretero-sigmoidostomy with Continent Pre-anal Colostomy

Presented in a Symposium on Urinary Diversion,
Minneapolis Academy of Medicine, November 17, 1958.

Surgical Technique

1. *Preoperative Preparation.*—After a definite diagnosis of carcinoma of the bladder is made and confirmed by transurethral biopsy of the lesion and bi-manual palpation under anesthesia of the area of the lesion has been done at time of cystoscopy and its fixation or non-fixation determined, a proctoscopic examination and air contrast study of the colon is done. If an excretory urographic series has not been performed prior to the cystoscopy and biopsy procedure, this is also in order. A survey of the chemical pattern of the serum consisting of blood urea nitrogen, creatinine, urea clearance, chlorides, sodium, potassium, carbon dioxide combining power and uric acid is obtained. Chest film in search of metastasis is made. Three days prior to surgery, the patient is placed on a low residue diet and the day prior to surgery the regimen of bowel sterilization as recommended by Poth[9] is started as follows:

At 12:00 noon the day before surgery (regimen is modified by Johnson[3]), 60 cc. of castor oil, 1.0 gm. of Neomycin with 250,000 units of Nystatin and 1.5 gm. of phthalysulfathiozole.

At 1:00 P.M., 2:00 P.M., and 3:00 P.M., 1.0 gm. of Neomycin with 250,000 units of Nystatin and 1.5 gm. of phthalsulfathiozole. These medications are given in the same amounts at four-hour intervals thereafter until the time of surgery, excluding the four-hour period prior to surgery, in order that the upper gastrointestinal tract may be empty and avoid any danger of vomiting during anesthesia. One hour before surgery, a rectal catheter is placed and one quart of 1 per cent Neomycin is instilled and the indwelling rectal catheter is clamped until the time of surgery.

2. *Anesthesia.*—Pentothal sodium with curare is administered intraveneously with supplemental nitrous oxide and oxygen via an intratracheal tube.

3. *Technique.*—The technique of the procedure is divided into the urologic procedures and

the proctologic procedures, the latter consisting of three parts: the abdominal field, perineal field in the first stage, and the revision operation seven to eight days after the first-stage operation.

4. *Procedure:* (1) *Urologic Surgery—First Step.*—Routine urethrocystoscopic examination is first made to determine the status of the urinary bladder as compared with the previous studies and areas of the biopsy are inspected. The bladder is thoroughly irrigated with a 1:5000 solution of aqueous zepherin solution and catheters passed if possible to both renal pelves and left indwelling. The left catheter with a straight end to indicate the left side (senestra, left, straight), and the right cut obliquely or diagonally (dextra, right, diagnonal). These catheters are splinted by an indwelling No. 16 French 5 cc. Foley bag catheter and again the bladder thoroughly irrigated with 1:5000 aqueous zepherin solution. The urethral catheter is connected to an irrigating unit with the flask of the unit filled with 1:5000 aqueous zepherin solution so the bladder may be filled with fluid as required during the procedure.

The patient is placed supine in low lithotomy position with well-padded knee crutches elevated 10 to 12 inches from the level of the table. All catheters and the patient are prepared with an antiseptic solution. Trendelenburg position with sand bag under the hips increases the exposure of the pelvic fossa. A midline incision is made from the symphysis to the mid-hypogastric area circumscribing and removing the navel. The rectus muscles are retracted lateralward after incising the linea alba. The pre-vesical and pre-peritoneal areas are explored and the peritoneum is not opened unless necessary prior to cystectomy. The loose tissue of the bladder is separated by blunt dissection and the peritoneum is stripped from the bladder and the urachus identified and doubly clamped and divided. The upper stump of the urachus is ligated and a traction suture is placed in the lower stump. The peritoneum is next stripped from the posterior surfaces of the bladder and if the peritoneum is found to be involved, the peritoneum is opened and the area of tumor involvement of the peritoneum is excised widely. The bladder is freed from its peritoneal attachment and pulled upward and the lateral surfaces of the urinary bladder are freed by sharp and blunt dissection. The vesical arteries are identified and particular care is given to the lateral vesical pedicles containing the superior vesical artery because of the proximity to the ureter. The ureters can be easily palpated with the indwelling catheters in place. The remainder of the vascular pedicles supplying the bladder are identified and doubly clamped, divided and ligated. The vasa are exposed as they cross the ureters, doubly clamped, divided and ligated. The ureters have been identified and are liberated as they enter the area of the bladder. They are divided including the indwelling catheters within the lumen and at this point the indwelling catheters are removed and polyvinal size No. 6 French catheters are inserted to the pelvis and the ends are treated as above, leaving the left straight and cutting the right at a diagonal. The indwelling catheters within the ureters are secured by single suture No. 000 chromic catgut placed at the distal end of the ureter. The catheters are placed to drip outside the operative field. With the bladder empty the base of the bladder is easily brought up into the wound and the attached seminal vesicles are stripped from the rectum and the rectum is completely separated from the posterior surface of the urinary bladder and the prostate. The pubo-prostatic ligaments are identified anteriorly and these are divided between forceps and ligated. The vascular plexus is also clamped and divided and ligated. The prostate is separated from its attachments by blunt dissection leaving the bladder and prostate attached only by the urethra which is divided by sharp dissection and left open as a secondary drainage point. The catheter in the urethra is an aid in this dissection and after the urethra and catheter has been cut across, the indwelling catheter is removed. Bleeding in this area can be controlled by packing and then suturing these areas with No. 000 plain catgut. All fatty tissue and lymph nodes in the area are dissected free and stripped down to the great vessels and to the anterior surface of the rectum.

After hemostasis has been secured in the entire area, the peritoneum is next opened and the abdominal contents carefully palpated, particularly the liver in search for metastasis.

2. *Proctologic Surgery—First Step.*—The proctologist's contribution to this operation commences with the division of the recto-sigmoid at its junc-

tion between two large Kocher clamps. The perirectal and pericolic fat is removed from the serosa of both segments of bowel particularly the rectal stump, in preparation for closure.

3. *Urologic Surgery—Second Step.*—An open uretero-proctostomy is performed under direct visualization. After thoroughly cleansing and irrigating the new urinary bladder with 1 per cent Neomycin solution, points at which both ureters easily reach the rectum are identified and a small incision, the size of the ureter, is made in a longitudinal plane through the rectal wall on its posterior-lateral aspect choosing a location so the ureter lies in the sacral curve. Each ureter is transplanted by grasping the previously placed fixation suture and the ureteral catheter and drawing both into the rectal lumen. The catheter is next passed downward toward the anus through a previously placed rectal tube. The mucosa-to-mucosa approximation of the ureter to rectum is carried out over the catheter with No. 000 atraumatic chromic catgut. The ease with which this can be accomplished is amazing because of the widely exposed operative area, but nevertheless it should be done cautiously and precisely. Three or four sutures are placed in the adventitia of each ureter and the adjacent rectum, being careful not to angulate the ureter.

4. *Proctologic Surgery—Second Step.* — The proximal rectum, measuring approximately 13 to 15 cm. from the anal verge is closed by approximating the mucosa with an inverting type Connell suture, then Halstead No. 3 silk sutures are used to approximate the sero-muscular layer, and avoiding the mucosal layer.

The sigmoid colon is mobilized next, in preparation for a perineal "pull-through" procedure by incising the lateral peritoneal reflexion up to the splenic flexure. Next, the inferior mesenteric artery and vein are doubly clamped, transected and ligated, just distal to the origin of the left colic artery and vein. This in most cases gives sufficient mobility, granting a semi-redundant sigmoid colon is present, to exteriorize the distal sigmoid colon well beyond the perineum. Particular care is taken to provide adequate vascularity by the marginal artery of Drummond in this procedure. No undue traction can be placed upon the bowel as it is prepared for the new perineal anus.

Perineal Phase.—At this point, the patient who is already in stirrups, is elevated to full lithotomy position and the perineal operator makes a semilunar incision along the anterior and anterior lateral margins of the external anal sphincter. Care is taken to preserve a skin island approximately 3 to 4 cm. in width between the former anus and the new anterior anal canal. The tissues of the perineum are carefully spread with a hemostat until the prostatic bed is encountered. Further dissection should be accomplished by blunt-finger method. The entire external anal sphincter is exposed around its external periphery to its lateral margins (Fig. 1).

The anal sphincter is carefully but forcibly dilated to admit at least 3 to 4 fingers. At this point we consider the division of the external anal sphincter to be an important contribution to the original operation as proposed by Johnson. The external anal sphincter is divided so the proximal one-half of the sphincter continues to encircle the former anus which is now the outlet of the new urinary bladder. The distal or caudal one-half of the sphincter, that is, the anterior and lateral phases are carefully and slowly dilated so that it will surround the "pull-through" colon which is soon to be introduced into its lumen. Next a large Carmalt hemostat is introduced through the prostatic bed and the abdominal operator introduces the distal sigmoid colon to this clamp. The bowel is carefully threaded through the perineum and through the divided caudal one-half of the external anal sphincter.

This is perhaps the most important part of the perineal dissection. It must be performed slowly and with considerable caution. If the colon is surrounded by considerable pericolic fat sufficient to produce marked tension upon the anal sphincter, longitudinal division of the sphincter in its anterior portion must be considered. The cut ends of sphincter can be marked with long silk sutures for future recovery. In case the tension is great, immediate postoperative strangulation will result. Approximately 6 to 8 cm. of "pull-through" bowel is exteriorized to compensate and allow for subsequent retraction. A large mushroom catheter is inserted in the "pulled-through" bowel and secured by a Daniel clamp. A vaseline gauze dressing is applied around the "pulled-through" bowel. The abdominal wound is then closed by the abdominal operator, establishing drainage from the space of Retzius with no attempt being made to

peritonealize the pelvic floor. A sterile rubber glove is placed over the Daniel clamp including the rectal tube in the new rectum. The ureteral catheters are secured to the perineal skin just of the oral route. An excretory urogram is done on the fifth or sixth postoperative day. The ureteral catheters are removed on the seventh day and the bladder catheter is left in place.

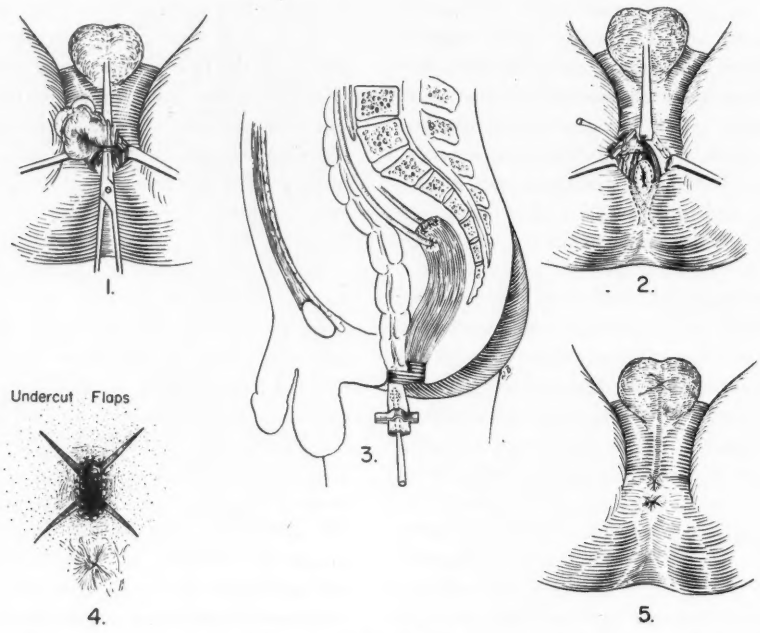

Fig. 1. Reconstruction of anus with rectal bladder (Garske-Sherman). *Perineal Phase I:* (1) Sigmoid colon carefully teased through caudal half of external anal sphincter. (2) Large mushroom catheter secured in bowel with a Daniel clamp, placed 7 to 8 cm. from sphincter. (3) Sagittal view to demonstrate treatment of external anal sphincter muscle. *Perineal Phase II:* (4) Redundant bowel amputated, sutured to undercut perineal skin flaps, to obviate mucosal prolapse. (5) Final postoperative result.

distal to their exit from the rectal catheter in the new bladder. Both ureteral catheters and the catheter in the new bladder are connected with a sterile plastic tubing to a urinary drainage bottle.

4. *Postoperative Care (Early).*—Patient should be weighed daily. Fluid and electrolyte balance is maintained by daily intravenous fluids based on daily chemical serum pattern determinations. Nasal suction is utilized until bowel activity returns to normal function and then removed. Supplementary parenteral vitamins and antibiotics are a must. Careful fluid intake, and output of ureteral and new bladder catheters must be carefully recorded. Ambulation usually the second postoperative day. As soon as possible after the suction has been removed a soft low salt diet is ordered and parenteral medications are discontinued in favor

5. *Proctologic Surgery—Third Step (Excision of the Redundant Bowel: Revision Operation).*—Approximately seven to eight days postoperatively, depending upon the condition of the patient, he is returned to the operating room. Under spinal anesthesia, in a "jack-knife" position, the redundant bowel is excised over a Payr clamp. Particular care must be made to free the bowel from the surrounding perineal tissues, and the Payr clamp must be placed at a level corresponding to the cephalad portion of the divided anal sphincter. In case the sphincter muscle has been divided to avoid strangulation of the "pulled-through" bowel, it can be reconstructed at this stage of the procedure. Care at this point will insure against subsequent mucosal prolapse and a bothersome wet anus due to mucosa extending beyond the anterior portion of the anal sphincter. Next, three

or four flaps of perineal skin are developed by undercutting; these are sutured with interrupted 00 chromic catgut sutures to the mucosa and muscularis of the recently excised bowel. This is done much as the standard anoplasty for mucosal prolapse of the rectum. Upon its completion, a vaseline gauze dressing is applied (Fig. 1).

Postoperatively, the patient is administered hot packs to the anal area for several days to be followed by Sitz baths. As soon as the anal edema has subsided, the patient is instructed in the use of sphincter exercises. The new bladder catheter is removed on the ninth postoperative day.

6. *Future Follow-up.*—The patient is discharged with:

1. A low salt diet.
2. Soda bicarbonate.
3. Antibiotic or chemotherapeutic agent specific for organism found on sensitivity and culture of the urine from the new bladder.
4. Residual urine is checked at each office visit and the residual is examined microscopically and cultured. The culture is plated and sensitivity studies run to determine medication of choice.
5. Instructions for sphincteric exercises are given.
6. Rectal irrigations.
7. Cathartic.

Serum chemical patterns are done monthly. Excretory urograms are done at three, six, nine, and twelve months for the first postoperative year and then every six months thereafter. A cystoscopic examination with chromorectoscopy (indigo carmine intravenously) is done in six months, and retrograde rectograms for reflux at three months postoperative.

Amphetamine sulfate and decrease in oral fluid intake after late afternoon will control nocturnal enuresis.

Report of Cases

Case 1 (B.R.L.J.—Age: thirty-six).—Admitted February 11, 1958, with a history of sudden onset, one week prior to admission, of gross total painless hematuria with the passage of one large clot. The patient had had an episode of "flu" and he attributed the possibility of the urinary bleeding to reaction from an acute infectious process. He had noted a similar episode two months prior to admission which lasted intermittently with the voidings for two days. He noted no renal pain or discomfort, nocturia, increased frequency, or dysuria. The patient had a meatal stenosis in 1938 treated by meatotomy and dilatation without symptoms since the surgery.

Physical examination revealed an alert, well developed, well nourished, co-operative white male with a normal temperature, pulse, respiration and blood pressure. No abnormalities of the head, neck, heart, lungs and chest were noted. Examination of the abdomen was normal. Normal male genitalia were noted with the exception of a small scar from the previous meatotomy. The prostate was found to be symmetrical and of normal size, shape and consistency and without tenderness or induration, and no supra-public abnormality was found. The remainder of the rectal examination was normal.

Laboratory Findings.—The hemoglobin was 15.8 gm., 9,000 leukocytes with a normal differential. The serology was negative. The sedimentation rate was 7 mm. in one hour. The urine was grossly bloody with a pH of 5.5, specific gravity of 1.032, two plus albumin, negative sugar and acetone and packed fields of red blood cells on microscopic study. The urine culture was negative.

Admission chest film showed no abnormalities. An excretory urographic series on February 12, 1958, showed no abnormalities on the preliminary film prior to injection of contrast material. After injection of 20 cc. of 30 per cent Urokon, the excretion rate of the contrast material was normal bilateral and there were no abnormalities noted in either kidneys or ureters. Three irregular overlapping filling defects, 2 to 3 cm. in diameter were noted in the right hemisphere of the urinary bladder and the outline of a Foley bag catheter could be seen deflected to the left of the midline (Fig. 2).

Cystoscopic examination on February 13, 1958, using pentothal, curare, nitrous oxide and oxygen anesthesia revealed an external urethral meatus with a small scar from the previous meatotomy. The urethra was otherwise normal. A low grade, chronic, non-specific prostatis was noted. The bladder urine was grossly bloody and several small clots were noted on the floor of the bladder. There was no evidence of intra-vesical calculus, foreign body, or diverticulum. Situated over and obscuring the right ureteral orifice was a soft friable, papillary tumor measuring 1.5 cm. in diameter implanted on a broad base beyond the orifice and extending up the lateral wall of the bladder to the region of the vesical neck. The tumor was a typical papillary carcinoma with superficial necrosis, sloughing, and evidence of recent hemorrhage, and elevated 1.5 cm. from the mucosa. Two discreet papillary tumors each elevated 1 cm. from the bladder mucosa and measuring 1.5 cm. in diameter and implanted on broad bases were noted on the roof of the bladder neck, extending into the bladder proper. The left ureteral orifice was normal in size, shape and position and clear urine was seen to appear from it at regular intervals. Two papillary tumors with narrow stalks each 3 mm. in diameter were seen just beyond the left ureteral orifice. Bi-manual examination revealed no evidence of extra-vesical fixation of the bladder in any of the areas described. Transurethral resection of the above tumors well into the

Fig. 2. (R. J.) Ten-minute film of the preoperative excretory urographic series, February 11, 1958, showing normal upper urinary tracts and multiple filling defects in the urinary bladder produced by tumor, and a filling defect of an indwelling Foley bag catheter.

Fig. 3. (R. J.) Five-minute film of the excretory urographic series, fifteenth postoperative day showing normal upper urinary tracts.

Fig. 4. (R. J.) Five-minute film of the excretory urographic series two months postoperatively showing well-filled, well-outlined normal upper urinary tracts.

detrussor muscle and beyond the edges of the bases was done. The areas were thoroughly fulgurated.

Pathology Report.—Clinical diagnosis of papillary transitional cell carcinoma grade II of the urinary bladder. *Gross:* The tumors were submitted as separate specimens, a total of approximately 5 gm. of irregular papillary fragments of pale grayish fragments of tissue measuring up to 8 to 10 mm. in diameter. *Microscopic Section:* Showed very cellular tumors of transitional type epithelium with marked irregularity of the cells and occasional mitotic figures and invasion into the underlying sub-mucosa. Definite areas of recent hemorrhage and also of necrosis were noted in all sections. Most of the tissue showed a general uniformity of histologic structure. The basal margins of the tumors were well demarcated in most instances although a few areas showed definite infiltrative type of growth into the bladder surface of the detrussor muscle.

Final Diagnosis: Papillary transitional cell carcinoma of the urinary bladder grade II.

Postoperative Course.—The patient tolerated the procedure well and on the fifth postoperative day a repeat cystoscopic study was done. Findings at this time were as noted above with the exception that the tumor areas had been resected and there was fulguration necrosis present in all areas. The good general physical condition of the patient and his age were considered and coupled with a review of the pathological studies it was felt that a radical cystectomy with urinary diversion was the procedure of choice. The patient did not wish to have fecal or urinary orifice on the abdominal wall and it was elected to attempt a Gersuny type operation.

The preoperative blood urea nitrogen was 12 mg. per cent, creatinine 1.6 mg. per cent, CO_2 combining power 25.8 milliequivalents per liter, serum chlorides 94 MEq./l., serum sodium 142 MEq./l. and serum potassium 4.2 MEq./l.

A proctoscopic study was normal. Air contrast colon study demonstrated no abnormalities.

On February 25, 1958, a prostatoseminalvesiculocystectomy with a Gersuny type disposition of the ureters and colon was accomplished in eight hours and forty minutes.

Pathology Report.—Gross: The specimen from a total cystectomy measured 9x5x5x4 cm. The bladder mucosa was shrunken and irregular with multiple areas suggesting tumor infiltrate or recent surgical fulguration. Multiple sections through the wall of the bladder revealed no evidence of infiltration in the muscle wall and several irregularities in the mucosa were taken for section from the sites of the previous resection. *Microscopic:* Section through the tumor areas showed evidence of recent transurethral resection with rather heavy fulguration and marked necrosis of the tissue. In one area of the urinary bladder on the right lateral wall there was infiltration of tumor into and partially replacing a portion of the muscle wall, but only invading a millimeter and not penetrating through the entire muscle wall of the bladder. The remainder of the sections showed only superficial alteration of the mucosa with no penetration into the muscle wall. Perivesical and pelvic lymph nodes showed no evidence of neoplasm.

Final Diagnosis: Papillary transitional cell carcinoma of the urinary bladder, grade II.

The patient's postoperative course was satisfactory.

The second stage revision operation was done on the ninth postoperative day. The ureteral catheters were removed on the seventh postoperative day and the "rectal bladder" catheter was removed on the tenth postoperative day. Diurnal urinary control was excellent and the patient noted sensation of filling of the rectal bladder with an urge to urinate at approximately one-hour intervals during the day and every two hours at night. On the fourteenth postoperative day, the patient was catheterized for residual urine and approximately 140 cc. of urine was obtained. An excretory urographic series was done on the fifteenth postoperative day and showed normal upper urinary tracts (Fig. 3). The patient had some difficulty in controlling the fecal stream initially because of diarrhea, presumably induced by the use of the antibiotics, however when this was controlled and at the time of his discharge on the twentieth postoperative day, he noted a normal sensation of filling of the rectum and was able to empty a part of the rectal contents with defecation effort and the remainder by a small tap water enema.

Serum patterns of electrolytes were done on the second, eleventh, and nineteenth postoperative days and were normal in all respects for each series of determinations.

The patient was seen on the twenty-seventh postoperative day and stated that the fecal stream control was satisfactory, and that the urinary stream control was not as satisfactory as at the time of discharge in that he had noted occasional nocturnal enuresis. Residual urine was 45 cc., and a moderate pyuria was present. The tidal volumes of each voiding were within the normal range, and the pattern of voidings throughout the twenty-four-hour period was similar to that prior to cystectomy.

Second Admission.—The patient was re-admitted to the hospital on April 21, 1958, after experiencing a sudden chill with fever to 104° F. There was no evidence of renal tenderness at the time. The urinalysis showed only 12 to 15 white blood cells and an occasional red blood cell. No abnormalities were found to account for the fever and chill. An excretory urographic series on April 24, 1958, showed excellent function bilateral with no evidence of stasis or dilatation of the ureters, pelves or renal calyces, and the pyelograms were interpreted as normal (Fig. 4).

Third Admission.—The patient was admitted on July 6, 1958, at which time an excretory urographic series showed no change from the last previous examination on April 24, 1958. The serum electrolyte pattern was normal. The urinalysis showed 8 to 10 white blood cells per high power field. Examination of the rectal pouch with a No. 21 French Brown-Buerger cystoscope revealed a normal anal orifice with normal sphincteric control. There was a tortuosity in the lower third of the rectum or new bladder, consistent with the usual contour of the rectum. The rectal folds were normal except for a minimal generalized hyperemia from the presence of urine. The urine itself was clear with some excess mucus within the deep mucosal folds. The capacity of the new pouch was approximately 10 oz. (Fig. 5). On either side of the proximal mid-lateral walls of the rectum could be seen two elliptical ureteral orifices from which clear urine appeared at regular intervals. Chromocystoscopy with indigo carmine showed vigorous jets of the dye-stained urine from the orifices.

Fig. 5. (R.J.) Left oblique cystogram showing the rectosigmoid bladder five months postoperatively.

A rectogram exposure made after instilling 10 oz. of 15 per cent Skiodan failed to show any evidence of reflux to the upper tracts on the initial filling, and a second, made after defecation effort also showed no evidence of reflux (Fig. 6). The serum electrolyte pattern was normal. The patient was discharged on July 8, 1958.

The patient has been seen intermittently in the office since and the residual urine has been approximately 10 to 20 cc. at each visit. An occasional erythrocyte, 7 to 12 leukocytes and an occasional clump of bacteria per high power field have been observed. Urine cultures have showed an occasional growth of *E. coli* but otherwise have been sterile. The patient has excellent control of both the urinary and fecal streams and has returned to his position as an executive in a plastic firm, carrying out his duties without difficulty. The patient has experienced normal sexual relations since the fourth postoperative month.

Case 2 (J. P.—Age: forty-four).—Admitted to the hospital on May 16, 1957, with the complaint of "coffee colored urine" noted intermittently for three days, two weeks prior to admission. The patient had observed two previous similar episodes, the first six months prior to admission with a duration of one day, and the second, one month prior to admission for two days. There was some mild increase in urinary frequency during the week prior to admission. No dysuria, nocturia, chills, fever, costovertebral angle tenderness or decrease in the caliber and force of the urinary stream was noted. Bilateral

contusion of the testes twenty years prior to admission was the only prior genito-urinary tract history. Complete review by systems was negative with the exception of bilateral varicosities of both lower limbs.

Physical examination revealed an alert, well developed, well nourished, cooperative white male with a

Fig. 6. (R. J.) Retrograde rectogram made five months postoperatively showing the configuration of the recto-sigmoid bladder and no evidence of reflux to the upper urinary tracts.

normal temperature, pulse, respiration and blood pressure. No abnormalities of the head, neck, heart, lungs and chest were noted. Examination of the abdomen was normal. Normal male genitalia were noted. The prostate was found to be symmetrical and of normal size, shape and consistency and without tenderness or induration, and no supra-prostatic abnormality was found. The remainder of the rectal examination was normal. Bilateral varicosities of the long saphenous veins were noted with moderate stasis pigmentation present over the anterior aspect of the left lower leg.

Laboratory Findings.—The hemoglobin was 16 gm., 10,250 leukocytes with 67 per cent polymorphonuclear, 32 per cent lymphocytes and 1 eosinophil. The serology was negative. The blood type was O Rh positive. Sedimentation rate was 28 mm. in one hour. The urine was grossly clear amber with a pH of 5.5, specific gravity 1.018, one plus albumin, negative sugar and acetone, and 25 to 30 leukocytes and 25 to 30 erythrocytes per high power field on microscopic study. The urine culture was negative.

Admission chest film showed no abnormalities. An excretory urographic series on May 16, 1957, showed no abnormalities on the preliminary film prior to injection of contrast material. After injection of 22 cc. of 30 per cent Urokon, the excretion rate of the contrast material was normal bilateral, with no abnormalities noted in either kidney or ureter. Two well-defined filling defects, each approximately 2 cm. in diameter, were noted in the urinary bladder—one situated in the left inferior lateral aspect and the second in the left lateral aspect of the bladder (Fig. 7).

Cystoscopic examination on May 17, 1957, using penthothal, curare, nitrous oxide and oxygen anesthesia revealed a normal external urethral meatus, distal and proximal urethra, and prostatic urethra. The bladder urine was clear amber, grossly. There was no evidence of intravesical calculus, foreign body or diverticulum. There was a considerable amount of edematous reaction close to the urethra and vesical neck, particularly on the floor on the left side. It was difficult to determine whether this was a simple inflammatory reaction secondary to a tumor process or extension of a tumor. Both ureteral orifices were normal in size, shape and position and clear urine appeared from each at regular intervals. A large papillary friable tumor mass was situated on the posterior-superior portion of the urinary bladder to the left of the midline measuring approximately 3 cm. in diameter. On the mucosa surrounding this area were a number of dilated, tortuous veins. There was a similar friable papillary tumor mass situated on the left wall of the bladder just beyond the left ureteral orifice extending up the lateral wall of the bladder to 1:00 o'clock on the circumference of the bladder. Both tumors appeared to have broad bases measuring approximately 1 to 1.5 cm. in diameter and were elevated 1 to 1.5 cm. from the mucosal surface. Rectal and bi-manual examination did not reveal any evidence of fixation or extension of the growth into, or through, the bladder wall. Transurethral resection of the tumors into the detrussor muscle and beyond the edges of the bases of the tumors was done and the areas were thoroughly fulgurated.

Pathology Report. — Clinical diagnosis of papillary transitional cell carcinoma grade II of the urinary bladder. *Gross:* 10 gm. of irregular papillary fragments of pale, grayish firm fragments of tissue measuring up to 1 cm. in diameter and 1 cm. in thickness were submitted for analysis. *Microscopic Section:* Showed a very cellular tumor of transitional epithelium joined in large blunt folds from the surface of the sub-mucosal connective tissues. There was uniformity in most of the histologic structure although mitotic figures were found relatively frequently at the base areas. Basal margins of the tumor were quite well demarcated although in a number of areas there was definite infiltrative type of growth into the bladder surface of the detrussor muscle.

Final Diagnosis: Papillary transitional cell carcinoma of the bladder, grade II.

Postoperative Course.—The patient tolerated the procedure well, however on the eighth postoperative day he developed pain in the right anterior chest, an elevated temperature, and a thrombophlebitis was found in the left thigh and lower leg. It was the impression that the patient had a pulmonary embolism, and this was confirmed by radiographic studies. Surgical consultation suggested a bilateral high saphenous ligation on the

thirteenth postoperative day. The patient's postoperative course thereafter was uneventful and he was discharged on the nineteenth postoperative day.

Second Admission.—The patient was re-admitted on September 4, 1957, and on September 6, 1957, a recheck cystoscopy revealed the left ureteral orifice slightly distorted by scar tissue from the previous resection. Just lateral to the left ureteral orifice on the roof of the intra-luminal portion of the ureter was a 2x4x4 mm. nodule of tissue which resembled a recurrent area of carcinoma. The scar from the previous transurethral resection could be seen on the posterior-superior wall of the urinary bladder and no recurrence was present. The left lateral wall was well scarified, except for one area of edema, 3 mm. in diameter, at 3:00 o'clock, which was suspicious of recurrence. The areas were resected and the bases throughly fulgurated. The microscopic study showed irregular masses of transitional epithelium with considerable pleomorphism and an occasional mitosis with infiltration to the deeper portions of the resection area. Changes were limited to the submucosa and mucosa without evidence of extension into the detrussor muscle. A diagnosis of transitional cell carcinoma grade II was made, and was similar in all respects to the first sections. The patient's postoperative course was satisfactory and he was discharged on the fifth postoperative day (Fig. 8).

Third Admission.—The patient was re-admitted on December 5, 1957, and a cystoscopy on December 6, 1957, again showed the distortion of the left ureteral orifice. There was an irregular well-scarified area in the bladder at the site of the resection on the left lateral wall with evidence of recurrent tumor. There was a well-healed scar on the posterior-superior wall of the bladder without recurrence of tumor in this area. Lateral to, and beyond the right ureteral orifice was a small papillary tumor measuring 4 mm. in diameter on a narrow pedicle, which was resected transurethrally and the surrounding tissue fulgated. Microscopic study showed transitional epithelium with an irregular pattern and mild cellular pleomorphism suggestive of transitional cell carcinoma. No mitotic figures were seen, but with the previous history, it was regarded as a papillary carcinoma of low grade malignancy (grade I). He was discharged on the sixth postoperative day.

Fourth Admission.—The patient was re-admitted on March 16, 1958, for a recheck cystoscopic study. The left ureteral orifice was more contracted and distorted than previously noted. Several recurrences of papillary carcinoma were seen: (1) 3x4 mm. in diameter medial to the right ureteral orifice, (2) 3x5 mm. in diameter situated on the roof of the intra-mural portion of the right ureter, (3) 3x5 mm. in diameter anterior and adjacent to the scar on the left lateral wall, (4) 4x4 mm. in diameter internal to the vesical neck at approximately 1:00 o'clock, (5) two tumor areas on the posterior-superior wall adjacent to the cystoscopic bubble each measuring 6x8 mm. in diameter, (6) 10x12 mm. in diameter on the roof of the bladder just internal to the vesical neck at the 12:00 o'clock position. Each recurrence was resected transurethrally and the base and surrounding area fulgated. The nodules were submitted separately for examination. The bladder, on bimanual palpation, at this time showed no evidence of induration, or suggestion of fixation to any of the surrounding structures, or to the lateral pelvic walls. The microscopic report of the representative sections showed transitional cell carcinoma grade II identical with the tissue obtained at the first and second resections.

Final Diagnosis: Papillary transitional cell carcinoma of the urinary bladder grade II with a rare section showing superficial invasion into the detrussor muscle.

The rapidity with which this patient developed recurrences of carcinoma of the urinary bladder suggested that transurethral resection and fulguration was not sufficient to provide a cure or control of the process. His good general physical condition, in spite of a pulmonary embolism, and our inability to cope with the recurrence of tumors by transurethral means warranted a radical cystectomy with urinary diversion. The patient did not wish to have a fecal or urinary orifice on the abdominal wall, and a Gersuny type operation was advised. The preoperative hemogram was normal in all respects, sedimentation rate was 23 mm. in one hour, blood urea nitrogen 16.5 mg. per cent, creatinine 1.9 mg. per cent, CO_2 combining power 21.8 mEq./l., serum sodium 140 mEq./l. The chest film was normal. Air contrast colon study was normal. The proctoscopic study showed mixed hemorrhoids grade I. On March 26, 1958, a prostatoseminalvesiculocystectomy with a Gersuny type disposition of the ureters and colon was accomplished in seven hours and twenty minutes.

Pathology Report.—Gross: The specimen from a total cystectomy measuring 13x5x6.5x5 cm. The bladder was open through the urethra and anterior aspect with the incision extending over the dome. The exposure of the mucosal surface revealed diffuse edema of the interureteric ridge and the areas of the previous transurethral procedures both old and recent were seen. *Microscopic:* Sections of the areas through the resected papillary tumors as well as random sections in various areas of the mucous membrane showed no tumor present. There was no neoplastic change in the muscularis of the bladder. Random sections of the bladder mucous membrane showed an unusual morphological appearance in that it was much more basophilic than normally seen, and there was general immaturity of the epithelium suggesting a generalized dysplasia. There was no extension of the neoplasm beyond the limits of the bladder wall. Peri-vesical and pelvic lymph nodes showed no neoplasm.

Final Diagnosis: Papillary transitional cell carcinoma of the urinary bladder grade II.

The patient's postoperative course was satisfactory. The revision operation was done one week following the Gersuny procedure. The ureteral and rectal bladder catheters were removed on the tenth postoperative day. Diurnal urinary control was excellent but he was

enuretic two to three times each night. On the twelfth postoperative day the patient was catheterized for residual urine and approximately 80 cc. of urine was obtained. An excretory urographic series was also done on the twelfth postoperative day and showed a moderate right hydronephrosis and a normal left upper urinary tract. (Fig. 9). The patient had some difficulty initially in controlling the fecal stream, but it gradually improved and was complete on the day of his discharge, the twenty-fifth postoperative day. Serum patterns of the electrolytes were done on the fifth, tenth and twentieth postoperative days and except for a very

Fig. 8. (J. P.) *(upper right)* Eighteen-minute film of the excretory urographic series of September 5, 1957, showing faintly-filled but normal upper urinary tracts and the absence of previously noted large filling defects in the urinary bladder. This series was made prior to the second transurethral resection.

Fig. 9. (J. P.) *(lower left)* Five-minute film of the excretory urographic series, twelfth postoperative day showing normal left upper urinary tract, and calyectasis and pelviectasis of the right kidney consistent with a moderate hydronephrosis.

Fig. 10. (J. P.) *(lower right)* Ten-minute film of the excretory urographic series sixty-six days postoperatively showing well-filled and well-outlined upper urinary tracts with some minimal dilatation of the right renal pelvis and calyceal system, and a normal left upper urinary tract.

minimal increase in the blood urea nitrogen to 21.7 mg. per cent on the fifth postoperative day, the remainder of the serum pattern remained well within normal limits.

The patient was seen on the thirtieth postoperative day and stated that since he had been at home the fecal stream control was only fair, and that the sensation of defecation and rectal fullness was not as complete as noted just prior to discharge. The urinary stream was in complete control except for an occasional episode of nocturnal enuresis. The tidal volumes of each voiding were within normal range, and the pattern of the voidings throughout the twenty-four-hour period was similar to that prior to cystectomy. The residual was found to be 15 cc. and a mild leukocyturia was present. On the fifty-sixth postoperative day the serum pattern of the electrolytes was normal, the voiding pattern was normal, and the bowel control was much improved but with considerable constipation which was fairly well controlled by small daily rectal irrigations.

Fifth Admission.—Re-admitted May 30, 1958, for a re-evaluation at which time the serum electrolyte pattern was within normal limits. An excretory urographic series on May 31, 1958, revealed no abnormalities on the preliminary film and after injection of the contrast material prompt appearance was noted bilateral. Both kidneys were normal in architecture, and some minimal dilatation of the right ureter was demostrated (Fig. 10 and 11). The mild leukocyturia was still present and the residual urine was 40 cc. He was discharged on the fourth hospital day.

Sixth Admission.—The patient was re-admitted on August 28, 1958. The residual urine was found to be 40 cc. and 10 to 20 leukocytes were found per high power field. Examination of the rectum was a No. 24 French McCarthy Pan-Endoscope was made and demonstrated a very minimal reaction of hyperemia of the mucosa to the contained urine. Rectal pouch capacity was 360 cc. Indigo carmine was given intravenously and although neither orifice could be definitely completely visualized, two areas in the proximal-lateral folds of the rectal mucosa were visualized from which indigo carmine was seen to appear promptly and in good concentration. An excretory urographic series showed a normal left upper urinary tract and a marked decrease in the dilatation of the right upper urinary tract (Fig. 12). A rectogram was made with 300 cc. of 15 per cent skiodan and failed to show any evidence of reflux on the initial filling, and a second exposure made after defecation effort also showed no reflux (Fig. 13). The serum electrolyte pattern was normal. The patient was discharged on the third hospital day with a supply of amphetamine sulfate, 10 mg. spansules to attempt to control the enuresis.

The patient has been followed since discharge and has noted a definite improvement in the nocturnal enuresis from the use of amphetamine sulfate. A mild leukocyturia persists and the residual urine ranges from 30 to 45 cc. The control of the urinary and fecal streams is excellent. The tidal volumes of urine and the voiding pattern approach approximately normal. He has returned to his work as a auto body shop manager and carries out his work as he did prior to surgery.

Comment

It is our feeling that the Gersuny operation provides the patient with carcinoma of the urinary bladder or other condition in which urinary diversion is required with an:

1. Expected average longevity.
2. A satisfactory solution to the surgical condition of the urinary diversion.
3. It fulfills the three essential conditions required to make urinary diversion an ideal operative procedure in that it: (1) Provides for correction of the primary pathological problem or disease. (2) Provides the mechanisms for preservation of normal renal function and most important, (3) Provides the patient with continence of the urinary and fecal streams.

This procedure is ideally suited to the male patient, however it can be performed in the female as well, although we have had no experience with this.

The rectal reservoir for urine, although initially unsterile, eventually becomes a container of sterile urine and because of the absorptive qualities of the bowel in this region, there should be practically no interference with fluid and electrolyte balance. With a potentially sterile urine and practically no absorption from this bowel segment, obstruction to urine flow and pyelonephritis should be avoided, and initially normal upper urinary tracts should remain so after this procedure has been performed. The fecal stream has been diverted from the bowel reservoir and the problem of increased bowel pressures during defecation as in ureterosigmoidostomy is also avoid-

ed. The bowel reservoir for the urine can be emptied frequently under voluntary control and the same situation exists with regard to the bowel reservoir for the fecal material. The orifices

Fig. 12. (J. P.) Ten-minute film of the excretory urographic series five months postoperative showing decrease in the dilatation of the right upper urinary tract. Normal left upper urinary tract with no change from previous studies.

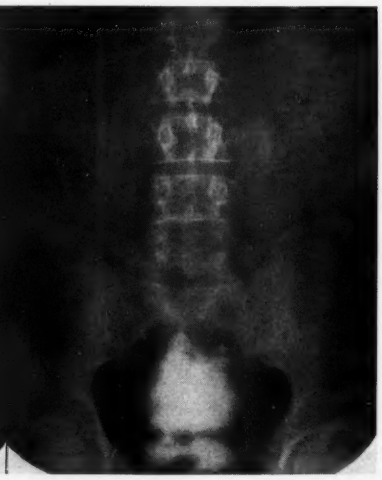

Fig. 13. (J. P.) Retrograde rectogram made five months postoperatively showing the configuration of the rectosigmoid bladder and no evidence of reflux to the upper urinary tracts.

are in a "natural" anatomical location and do not require the use of a collecting apparatus. The advantages over cutaneous ureterostomy, ureterosigmoidostomy, isolated segment of cecum, isloated segment of ileum are obvious. This operation is but a refinement of a diversion to the isolated rectosigmoid with diversion of the fecal stream by an abdominal colostomy, and avoids the use of a colostomy.

The three most popular methods of urinary diversion at this time are the ileal segment diversion, the isolated rectosigmoid with diversion of the fecal stream by abdominal colostomy, and now the Gersuny operation. The patient and his physician are faced with the problem of urinary incontinence from a stoma in the abdominal wall and collection of the urine by an appliance in the first instance, the use of a colostomy in the second instance, and in the Gersuny procedure, by a perineal colostomy with control and a urinary reservoir also with voluntary control, but with both orifices in a "natural" anatomic location. The latter would seem to be the more logical procedure of choice by both physician and patient.

The basic principles of ureteral and intestinal surgery must be fulfilled by any method of urinary diversion to avoid localized necrosis at the suture line of the anastomosis, leakage, peritonitis, etc. The vascular supply of the ureter must be preserved and during the procedure must not be twisted, traumatized or angulated. The exposure afforded by this method should, with careful technique of the operator, provide the most ideal situation for a ureteral-intestinal anastomosis.

The patient should have voluntary control of the urine almost immediately upon removal of the indwelling urinary reservoir catheter. Normal urge to empty the reservoir will occur immediately as soon as it begins to fill with urine. The capacity of the urinary reservoir will vary, but most ideally should be about 300 cc. with little or no residual after emptying. The voiding pattern should approach that of a normal voiding pattern of a normal urinary bladder with the voiding volumes approximately the same. The control of the fecal stream requires somewhat longer after the revision operation is done, but should be present in approximately two weeks. The new fecal reservoir should be emptied daily and is assisted by a small daily irrigation. The patient will develop a normal urge of bowel movement but will encounter some difficulty with control of flatus initially; this also becomes controlled with time.

As in all radical pelvis surgery on the male,

impotence is a problem and particularly after a cystectomy has been performed. One of the cases noted has had no problem in this regard.

The urine cell count initially will be very high, but as the bowel becomes adjusted to the contact with urine and the bacterial density becomes less, the urine becomes sterile with the aid of antibiotics and other chemotherapeutic agents.

There is no question that some electrolyte absorption does occur from the isloated rectal bladder (Boyce[14,15]), but normal or nearly normal function should offset this reabsorption.

Excretory urographic series will demonstrate normal upper urinary tracts in those patients with a normal urinary tract prior to surgery and an improvement in urinary tracts which have been dilated prior to surgery. The rectal bladder may assume a rather bizarre shape radiographically when filled with contrast material and an estimate of the amount of residual urine in the reservoir can be demonstrated by making an oblique cystogram of the contrast-filled pouch before and after the patient has voided.

Rectograms made with an inlying catheter in the rectal bladder and injecting the amount of contrast material estimated to be that of the capacity of the reservoir can be easily accomplished and a retrograde reflux rectogram made shortly after injection and again after removal of the tube and after the patient has emptied the new rectum, will show uretero-renal reflux if reflux is present.

Cystoscopic examination of the isloated rectum can be easily accomplished as an office procedure with no discomfort to the patient and the ureteral orifice can be visualized by chromocystoscopy after injection of indigo carmine.

Early diagnosis and subsequent early operation by this method of the select patient with carcinoma of the bladder or other surgical conditions of the bladder, should provide the patient with a situation which is economically and socially feasible for comfortable survival. This method should encourage more radical procedures in an earlier stage of the disease with a more satisfactory end result than other methods of urinary diversion.

Summary

1. Two cases of carcinoma of the urinary bladder in relatively young men treated surgically by the Gersuny operation with modification of the proctologic surgical technique are presented.

2. Principles of urinary diversion and their basis on the historical background of urinary diversion are reviewed with particular reference to this procedure.

3. The technique used in the two cases is outlined in detail as well as the immediate and late postoperative care.

Primary Hepatoma: Bone Metastasis as Initial Manifestation

The authors add one more consideration in the diagnosis of a patient who has lytic osseous metastases without evident primary tumor.

S. B. FEINBERG, M.D.
M. E. GOLDBERG, M.D.
Minneapolis, Minnesota

From the Department of Radiology, Mt. Sinai Hospital, Minneapolis, Minnesota.

NUMEROUS NECROPSY analyses have confirmed accepted medical opinion that primary hepatomas are rare.[1-7] This is true in spite of the fact that the liver is the site of more secondary neoplasms than any other organ, due to its size, blood supply, and location.[8]

It is not the purpose of this paper to discuss the pathology of hepatomas. Instead, it is the purpose of this discussion to emphasize that, in spite of their rarity, hepatomas are responsible for bone metastases of the lytic type which may have a loculated expanding configuration.[1,3,9-13] Unlike the majority of reported hepatomas, the case in question showed no evidence for cirrhosis either ante or postmortem.[2,6,8,10] Thus, the diagnosis must be considered by the roentgenologist when searching for the cause of lytic and/or loculated bone lesions (Figs. 1-4).

In Asia, and to a lesser extent in Europe, where cirrhosis is relatively more frequent,[8] hepatomas are more prevalent. In this country several surveys[1,3-7] quote the incidence of primary hepatomas as less than 1 per cent in thousands of autopsies. The records of the Boston City Hospital[6] show that the incidence of hepatomas has increased with the increasing number of cases of cirrhosis. In the many thousand necropsy series, the incidence of bone metastases varies between 1 to 3 per cent. In the reports pertaining to bone lesions as such, these figures do not apply, for these are selected surveys.[12,14-15]

Case Report

The patient was a white woman, aged sixty-three. In 1954 she was admitted for a simple Colles fracture. In June 1956, she was readmitted for low back, pelvis, and hip pain associated with depression. She had chest pain which in retrospect was due to a rib fracture. Physical examination and multiple laboratory studies including urine for Bence Jones protein, cerebrospinal fluid examination, blood sugar, calcium, phosphorus, serum protein determinations, and electrophoretic serum protein patterns were all negative. Roentgen evidence for osteoporosis, which was non-specific, was present. This had increased perceptibly in two years. She was subsequently treated with estrogens and testosterone.

The patient was readmitted on December 19, 1956, after suffering trauma to the head and neck. Since her last admission she had been well, in spite of the fact that she had discontinued her medication. The spinous process of D1 (Fig. 1-2) was fractured and showed poor definition of the break suggesting a pathologic fracture. Chest findings showed hilar, especially left, enlargement over the past six months. For the first time, a small left axillary lymph node was palpable and proved to contain metastatic carcinoma, primary site unknown. Further search showed an enlarged left supraclavicular node.

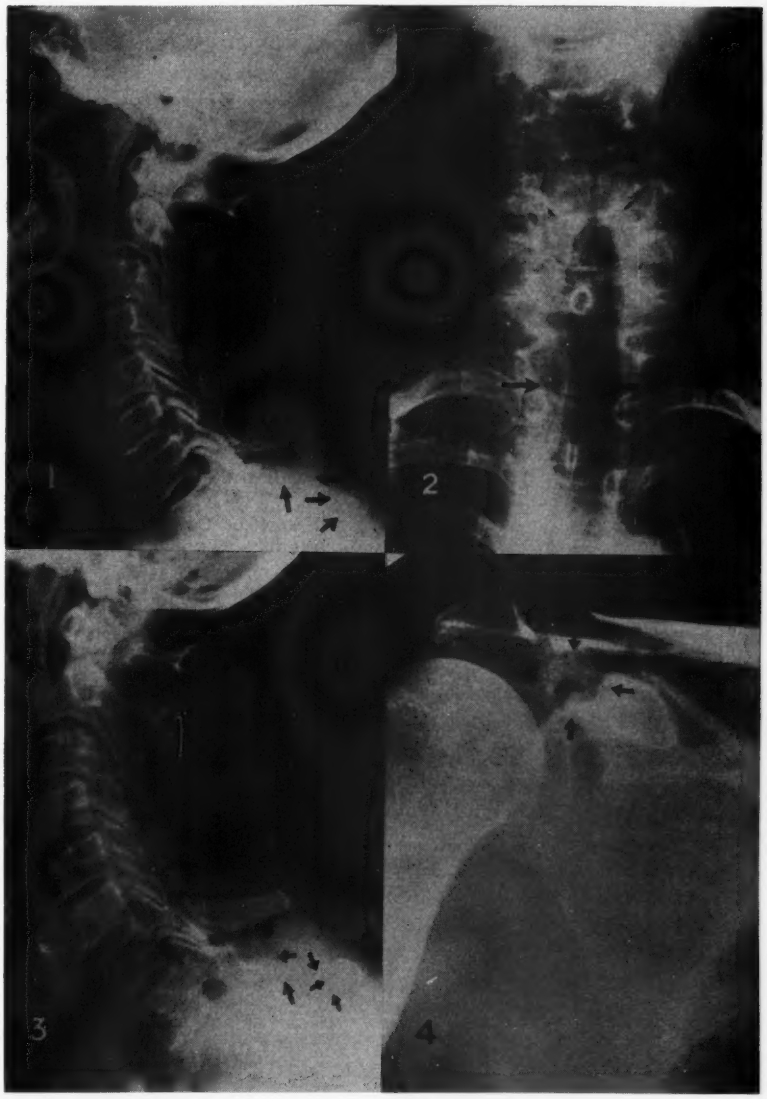

Fig. 1. Lateral cervical spine study taken in December 1956. Pathological fracture through spinous process of D1 with indistinct margins due to underlying lytic lesion.

Fig. 2. Anteroposterior view showing poorly defined spinous process as seen *en face* due to above-mentioned findings.

Fig. 3. Pathologic fracture through D1 relatively unchanged since December 1956 as seen on May 1958. The only change has been the degree of osteoporosis which has increased.

Fig. 4. May 1958 examination of right shoulder showing partially healed cystic, lytic neoplastic changes at base of coracoid process of scapula.

While living in San Francisco, she developed a lytic right scapular lesion which showed some response to

radiotherapy. In December 1957, she developed abdominal pain, leg pain, fatigability, and frequent bouts of perspiration.

On May 12, 1958, she was admitted again because of vertigo and cervical and interscapular pain. Physical examination showed a right submaxillary node, moderate hepatomegaly, and questionable jaundice. Bilirubin was 1.3 mg. per cent at one minute; the total being 2.8 mg. per cent. Bromsulphalein test was 66 per cent and the alkaline phosphatase level was 41 KA (King Armstong) units. Roentgen findings were limited to osteoporosis, destruction of the spinous process of D1, (Fig. 3), and partially healed cystic metastasis in the right scapula (Fig. 4). The old bilateral hilar enlargement, especially left, persisted. Gastric studies showed large liver and spleen indentations. Treatment consisted of cortisone, nitrogen mustard, and dilaudid.

Her last admission was on June 27, 1958. She was markedly jaundiced and was distended. The hepatomegaly had increased. She had pretibial edema. Renal function was diminished. Her sedimentation rate was 64 mm. per hour, serum bilirubin was 5.95 mg. per cent in one minute with a total of 10 mg. per cent, and prothrombin time was 69 per cent. She became comatose on June 31, 1958, and died on August 2, 1958.

Autopsy.—Gross pathology showed carcinomatosis, primary undetermined. Liver, spleen, lungs, mediastinal and peribronchial nodes, celiac and periaortic nodes, adrenals, dura, cerebellum, dorsum sellae, and sella turcica were all involved. The liver was replaced by tumor with intrahepatic biliary obstruction.

Microscopic examination revealed carcinoma in nodules and masses within vascular channels—both lymphatic and blood vessels. There were numerous bile thrombi. The structures varied between glandular and ductal.

Diagnosis.—Primary carcinoma of liver. No evidence for cirrhosis. Metastases to spleen, lungs, mediastinal and peribronchial nodes, adrenals, dura cerebellum, dorsum sellae, and hypophysis.

Discussion

This case emphasizes the difficulty frequently encountered in the diagnosis of hepatoma, from all points of view. In this case, the isolated finding of destructive bone lesions was the only early clue without any clinical or laboratory clue. In spite of several hospital admissions, laboratory studies, including "liver profiles" and numerous roentgen studies, the early positive findings were limited to a post-traumatic dorsal spinous process fracture. When the scapular lesion was discovered, gastric displacement by liver and spleen was already obvious. Hepatomegaly and icterus were late findings as were the positive laboratory findings. The course of events suggested the diagnosis of secondary, rather than primary neoplasm of the liver.

Summary

A case is presented to illustrate the necessity of considering the diagnosis of primary hepatoma in the over-all differential diagnosis, when lytic bone lesions are the only positive findings in an extensive battery of clinical and laboratory studies is presented. Bone metastases are found in a very small percentage of necropsies of patients with hepatomas; nevertheless, one should be aware of this possibility whenever one encounters a lytic and/or loculated bone lesion which cannot be traced to the more common renal, thyroid, bronchial, or the more rare primary sites of carcinoma involvement.

Emotional Problems of Middle Life

FRANCIS J. BRACELAND, M.D.
Psychiatrist-in-Chief, Institute of Living,
Hartford, Connecticut

Presented at the 67th Annual Meeting, Association of Life Insurance Medical Directors of America, Hartford, Connecticut, October 23, 1958.

THERE MAY BE specific sources of stress in middle life which make adjustment difficult. Illness, business reversals, rebuffs, disappointments in friends, failures of promotion, loss of face in business or in the community; all of these may threaten the man in middle life much more than they would have done earlier, for now there is a feeling of time moving rapidly and jeopardizing the chance of setting the reversals to right. In the mild depression, which inevitably accompanies any serious set-back, there sometimes arises a period of self-examination which may enhance the depressive mood. The man in middle age examines himself through the dark glasses of discouragement. He finds perhaps that he has to settle for much less than the objectives he once thought essential.

Worse yet, he may find that he has achieved all his goals only to find them empty of emotional satisfactions. Occasionally, a man in middle life will become depressed after having been promoted to the top position in his business or profession. Finding himself alone at this dizzy height and fearing lest he fall, he becomes depressed and anxious. The very successful man of fifty may have accumulated so much wealth, have so many obligations, offices, and memberships that he cannot get off the mad merry-go-round, even when for the sake of his health he needs to take time out. The moderately successful man may drive himself or be driven by his wife or his confreres toward greater and greater accomplishments with the swift passage of time. It is in this group, psychiatrists find, that definite anxieties may arise about a son, or a symbolic son in the person of a young man, who may threaten to displace him at home or in business. Such a man has never resolved certain conflicts with his own parents and he is therefore vulnerable in his role as an elder so that toleration of business rivals and of figures in the family itself may be stressful.

Equally pressed is he of mediocre accomplishment. More than ever he may find it incumbent upon himself to go forth and prove, at least to his

wife and family, that he is somebody important. Failure at this point is particularly bitter. He may well reach outside his family for appreciation and so estrange himself from what should be one of his greatest sources of satisfaction. This only adds to the stress of the middle years.

The emotional reactions to anticipated old age are in themselves a real source of stress. The fear of growing old in our urbanized, industrial age is very real indeed, for it usually signifies to men dependence upon others, loss of privilege, loss of respect and financial duress. Unfortunately, in these days in many positions we are old by fiat of a Board of Directors, as I have frequently stated before. We are capable and employable at sixty-four and old and retired at sixty-five; retired after the customary, honored-guest routine, which to the recipient simply means he is through. All of this is too close to the man in middle life for him to be comfortable, or for him to contemplate it with equanimity.

The emotional symptoms which arise in this life period are usually exaggerations of the normal personality, characteristics which were developed at a much earlier age. When these symptoms become severe and progress to the point where there is a break with reality, the individual is said to have a psychosis. Fortunately, these are relatively rare in men in the involutional period. The break, when it comes, is gradual and it appears because the individual has to accept something as psychologically true. He loses someone or something dear to him, worries, and becomes depressed. He may conclude that life is over for him. Physically, this may not be true, but psychologically, if his "life" was maintained by his investment in the person or thing now departed, then life, as he sees it, is empty.

The feeling of failure now seems overwhelming. Old conflicts revive and there is a decrease of physical strength and loss of the will to continue the battle. No matter what the precipitating cause, the resulting emotions are depression and despair or, if he blames others, delusions of persecution. Attention formerly expended on external interests is now turned on the self, with resultant increase in selfishness, egocentricity and hypochrondriacal preoccupation. Next comes a renunciation of friends and all pleasures, and if this state progresses, the results are sometimes deeper depressions and agitation. The depressions of middle life are no different from other depressions. Fortunately, at present modern psychiatric therapies have dramatically changed the prognosis of these depressions and the period of illness is much shorter than it used to be.

At times, the first evidence of trouble in this age group will be the discovery that the individual is becoming more dependent upon alcohol, for it offers temporary relief. Another group may seek undesirable companionship outside of the home, and still another may respond with hypochondriacal symptoms and a fixation on various organs or systems. We find in these groups many of the men who are thoroughly dissatisfied and unhappy in their professions, their jobs, their specialties, their health, their homes, their relationships and their accomplishments and who fail to recognize that their troubles are due not to their surroundings but to themselves. During this difficult period help rather than criticism is needed. It may be of utmost importance to prevent a man with the syndrome from making a drastic change of employment or marital status until he is free of his symptoms of illness. Should he do so, his last state is not infrequently worse than the first.

Society, in general, fosters a rather dismal outlook for people in their declining years. There is little question that one of our greatest needs is the development of an educational program to train people for adjustment to old age. This program should have the broad aim of anticipating and preventing the anxieties and maladjustments attendant on growing old. Such a program should not be delayed until middle life, it should be a continuing health measure from childhood.

In earlier times, the woman entered middle life with trepidation. Her biologic and her physiologic development made fear a commonplace. For many, this period becomes a time of soul-searching and regret—a period of anxiety, phobias, and fear of waning attractiveness in the tradition of the particular culture. Though much of this has lessened, still to many it is a time of emotional irritability coinciding with changes in the autonomic nervous system and some glandular changes. Psychologically, it is a time of change in the life of a mother who, after a period of arduous duties, now finds herself at comparative leisure. What she does with that leisure is important, as we note on all sides of us.

Emancipation from heavy responsibilities can in some instances result in a vacuum. We have mentioned before that women even more than men need to be needed and, like them also, when their sphere of operation and ministration is severely

restricted, they may be unable to contain their anxiety. It is then that there is danger of neurotic complaints and symptoms appearing. One sees here the need, in fact the necessity, for individuals to have outside interests—the church, the school, the community. Work in these spheres is in itself therapeutic; it prevents what Nietzsche called "the melancholy of everything completed." William James also commented upon this fact when he stated that "the sovereign cause of melancholy is repletion." We need things to do which are important and which give us an emotional return.

Of extreme importance to the normal woman is her concept of herself as a human being and the great dignity which is hers in the natural scheme of things. Since childhood she has learned to cherish ideas of her self-worth and to guard and appreciate her prerogatives. Now in middle age some women feel that this status and these prerogatives are threatened. Life has already poured out its most important gift and the woman may sometimes feel that her personal importance is diminished. In addition, she begins to fear the spectre of old age. Along with the lessening of responsibility there appears at this time an unmistakable increase in fatigability, a gradual loss of family or friends through death and through a variety of circumstances. In some women there also arises the necessity of becoming in some way self-supporting and this fact in itself introduces a whole new set of problems and adjustments. While most individuals handle these problems without too much difficulty, there are some women who become unduly insecure and insecurity is the foundation upon which anxiety and depressive symptoms arise.

If a woman has successfully handled the anxieties of her emotional development in the past, the chances are very good that she will do so again at this period of life. It is only the particularly rigid and unadaptable person who has difficulty when faced with the need for a change in outlook. Variability typifies the situation in women in middle age and it is unjustifiable to attempt to blanket them all into one great group. There are various kinds of personalities, with various kinds of environments and adaptive mechanisms, who meet various kinds of stress, and it is obvious that various kinds of reactions will be called forth.

We should pause here for a moment and consider another myth which has little or no foundation in fact. That is the inevitability of a great increase in weight in middle life. Also thought to be mysteriously connected with glandular change, it is known as "the middle-age spread." The middle-age spread is due to the same reason that spread at other times of life is due—namely the ingestion of too many calories, or to be blunt, to overeating. The proof of this, of course, lies in the fact that not all women are affected in this fashion. If it is pointed out that it occurs frequenly in mothers whose childbearing period is over, it can also be pointed out that they more frequently are prone to cook for the family and hence are more exposed to tasting, sampling and frequent snacks than are their sisters who are employed away from the home.

There is one psychological mechanism or means by which we handle our anxiety which we should mention here, namely, that of projection. Projection is the psychological temptation of shifting to others blame which we should accept ourselves. If this becomes a chronic method of handling problems or if it is indulged in regularly, it will have dangerous possibilities.

In people who are prone to go through life using this mechanism, when periods of stress arise as those about which we have been speaking, here is an easy way to handle it: blame someone. But this is fraught with danger, for it can be carried so far that it occupies one's mind to the exclusion of other means of meeting problems. Projection becomes the basis of paranoia and paranoia implies a series of delusional ideas. Delusions are fixed false beliefs and when they occupy our minds we are in danger of an emotional break. This situation is sometimes seen in middle life and called a paranoid condition. It is better to face up to problems and frankly assay and accept our deficiencies than to fall prey to an illness because we are prone to blame others.

To be mature emotionally implies that we have some knowledge of ourselves and our reactions, that at least we know something about them, particularly those which are weaknesses and those which we must guard against. Without this knowledge or some portion of it, we cannot exercise the control required of us in order to meet the difficulties which beset us. To be thought of as emotionally mature assumes also that we have the capacity to accept the duties and responsibilities of our station in life and that our ideals and our goals are worthwhile and within the realm of attainment. It assumes necessarily that we have learned that the world is not a large catering firm

made for our especial delectation and also that there are other people in the world who have rights equal to our own.

To be emotionally mature means that we evaluate things as they are in reality, not as they appear to us through the rose-colored glasses of fantasy or the bilious glasses of depression and misanthropy. To distort situations because of one's neurotic needs or frustrations is to court trouble. Under this heading we may place our view of our own selves. This should be real, with our various virtues and deficiencies known to us. To feel hopelessly inferior is to be tiresome and to call forth neurotic symptoms. All of us are inferior in some things and superior in others. To feel that we are definitely superior is to be insufferable and a bore. Everyone, sick or well, has an essential dignity and it is required of him that he respect others and respect himself. It is our task to determine our good qualities and our abilities and to develop them. To be emotionally mature means to be able to recognize and deal effectively with the emotional conflicts and tensions which are the lot of most of us. We may require help with some of the more pressing ones or the unconscious conflicts which assail us, but at least we are required to make an effort to handle our problems. It is our unresolved conflicts which are the cause of the symptoms which distress us and which basically are the cause of our maladjustments. The groundwork for them is laid in our early years and some of them come to fruition when we are under stress.

It was written by an old Roman centuries ago that men who have no resources in themselves for securing a good and happy life find every age burdensome (Cicero *De Senectute*).

Dedication of Diehl Hall

Introductory Remarks

ROBERT B. HOWARD, M.D.
Dean, College of Medical Sciences, University of Minnesota
Minneapolis, Minnesota

Diehl Hall was dedicated on January 22, 1959, at a dinner in Coffman Memorial Union.

IT IS A DISTINCT privilege for me to act as your Master of Ceremonies on this occasion when we have come together to honor our friend, Dr. Harold S. Diehl, Dean Emeritus of our College of Medical Sciences.

Before proceeding, please let me introduce guests at the head table: President and Mrs. J. L. Morrill, Dean and Mrs. H. S. Diehl, Reverend and Mrs. George Hall, and Mrs. Howard. With us in the audience are more than seventy-five members of the Legislature of the State of Minnesota; distinguished members of the Board of Regents of the University of Minnesota; Dr. Il Sun Yun of our sister university, Seoul National University; members of the Diehl family; and a host of friends and benefactors of the University and of the College of Medical Sciences in particular. I wish also to acknowledge with much appreciation the presence of Dr. W. Barry Wood of Johns Hopkins University Medical School, Dr. Edward Kass of Harvard University Medical School, Dr. Robert Williams of Western Reserve University Medical School and Dr. Lester Dragstedt of the University of Chicago Medical School, all of whom participated in today's Symposium on Medical Education, which, like tonight's dinner, was presented in honor of Dr. Diehl. This was a most interesting symposium, stimulating to members of our faculty and the student body. We are grateful to those who participated in it and also to Dr. C. P. Barnum, Jr., of our own Department of Physiological Chemistry, and members of his committee who worked with him in the development of this excellent program.

In trying to tell you something about our Dean Emeritus, I find myself confronted with a difficulty in communication. Communication at best is difficult. I was told recently that our armed forces have just about perfected a translation machine which will translate English into Russian, and vice versa. During a recent test, responsible officers in charge of the project decided to feed into the machine an English phrase which was to be translated into Russian and thence back into English. They chose the phrase "The spirit is willing but the flesh is weak." The machine clanked and whirred and various lights flashed. Within a short time the message came back, having been translated and retranslated, as follows: "The wine is fine but the meat is spoiled."

I certainly do not want whatever message I have for you to be garbled in this fashion. The story I want to tell is a simple one. As loyal members of *his* faculty, we of the College of Medical Sciences love, respect, and admire Harold Diehl as a physician, as a leader of medical thought, as a

superb administrator, and as a good friend. I do most fervently wish that I had powers of description equal to the task of painting the sort of picture of him that I should like to be able to do.

Dr. Diehl is a quiet, unassuming man. To my knowledge, he has never been hanged in effigy, nor on the other hand, has he been carried from the field on the shoulders of his players. His name has appeared only infrequently in the public press. The "man in the street" probably knows little of his work.

Yet those of us who have been privileged to work intimately with him—and there are, of course, many in this audience whose association with Dr. Diehl goes back much farther than my own—are sharply aware of his good judgment, his wisdom, his vision, and above all the mighty contribution he has made, directly and indirectly, to medical education and medical research.

I am reminded of the zoologist who finally succeeded in producing an animal which represented a cross between a parrot and a tiger. A friend asked him why he wanted to obtain such an animal, whereupon the zoologist replied "I don't know, but when he talks we sure listen!" This is the way that it has been for the past quarter century in the College of Medical Sciences. When Dr. Diehl talked we all listened—but in this instance, because we knew the things he had to say would be important to us.

Let me give you just a few highlights of Dr. Diehl's illustrious career. Born in Nittany, Pennsylvania, he entered the University of Minnesota Medical School in 1914. He received his M.D. degree in 1918 and, in that same year, joined Base Hospital 26, a University of Minnesota unit which served with distinction during World War I. Following the end of the war, Dr. Diehl served as Director of the North Division of the American Red Cross in Poland, a period of service during which his administrative talents first became obvious.

In 1921, he returned to the University, becoming Director of the University Health Service and also head of the Department of Preventive Medicine and Public Health. He served in these two posts until 1935, at which time he was appointed Dean. In 1937, as you know, he accepted a new position, Senior Vice President for Research in Medical Affairs and Deputy Executive Vice President of the American Cancer Society. He continued in the Deanship, however, on a part-time basis until June 30, 1958, at which time his retirement became effective.

His scientific work on the common cold and upon the control of tuberculosis is well known. He has been awarded many honors, and he has served, with great distinction, not only his college, his university, and his profession, but the American public as well. During and after World War II, he served in top-level national posts with important responsibilities relating to the assignment and utilization of medical manpower. His accomplishments in this important area have been widely recognized.

What might one say of the Deanship itself? I am reminded, in a negative sort of way, of the remark of one Alfredo Zacchini in explanation of his early retirement from the family circus act. "You been shot out of one cannon, you been shot out of 'em all." This is definitely not true of Medical School deanships. The Deanship at the University of Minnesota Medical School is something special indeed—special because it was made so by Harold Diehl. It was during his Deanship that Minnesota rose to take its place among the nation's top medical schools, that its scholarly productivity attained national and international recognition.

A recognized medical educator, Dr. Dana Atchley, once said "Universities should study the epidemiology of ideas." Certainly our University has been such a student, and the College of Medical Sciences, under Dr. Diehl's direction, has been a place where the infectiousness of ideas has been carefully fostered, where the contagiousness of curiosity has led to an epidemic of truth-seeking.

Because of our deep feeling for Dr. Diehl, because of his truly outstanding contributions, we are honored that one of our most important buildings —one with an intimate relationship to the College of Medical Sciences—will bear his name.

President Morrill's later words will mark the formal naming of this building. First, however, let me proceed with the ceremony which will result in preparation for the cornerstone for the new building. In the center of the room is a copper box. I will ask a number of friends and associates of Dr. Diehl to come forward and to place in the box certain items representing highlights of Dr. Diehl's career.

Later, the box will be sealed and placed in the cornerstone of the building. We do not, of course, know under what circumstances this box will be opened hundreds of years hence. We feel confident,

however, that historians of that distant age will recognize in these memorabilia, the accomplishments of Harold S. Diehl as those of a true leader of men.

Will the following individuals please come forward?

Dr. John L. McKelvey
Microfilm of 1918 Graduation Program of Medical School.
Picture of Dr. Diehl in Red Cross uniform.

Dr. O. H. Wangensteen
Microfilm of Dr. Diehl's first publication.
Page proofs of Dr. Diehl's latest publication.

Dr. Ruth Boynton
Bottle of copavin.

Dr. Gaylord W. Anderson
Microfilm of copy of *Healthful Living*.

Dean H. Mead Cavert
Program for Symposium and tonight's dinner on Medical Education.

Dr. Howard Conn
Picture of Dr. and Mrs. Diehl with their two children.
Picture of Dr. and Mrs. Diehl with their seven grandchildren.

Finally, let me mention two additional points. The first is the contribution made over these many years by Julia Diehl. She has truly been the perfect Dean's wife, working at Harold's side, helping him, and encouraging him. On many occasions, he has spoken of the role she has played, and it is fitting that this role should be acknowledged and emphasized tonight.

Secondly, I want to acknowledge my own very deep gratitude to Dr. Diehl. It was he who gave me the initial opportunity to enter the field of medical education and administration, a field I have found fascinating and stimulating, largely because he made it so. I have had a unique opportunity of working with him during the past several years. I have learned much from him, and I can only hope that I have learned enough to be able to carry on the traditions of this great College which Dr. Diehl has done so much to build.

And now let me introduce the President of our University, Dr. James Lewis Morrill, who will present the dedicatory address.

Dedicatory Address—Diehl Hall

JAMES LEWIS MORRILL, LL.D., L.H.D.
President, University of Minnesota
Minneapolis, Minnesota

IT IS a somewhat unusual and even premature occasion that we share this evening to "dedicate" a building still being built—and, by authority of the Regents, to give it the name that it so well deserves. But a very happy one, indeed.

Without meaning to be sacrilegious, surely—we are kind of "canonizing" Dean Diehl in advance of complete construction—something new in the tradition of this University: designating him a Saint of the Medical Sciences, so to say, in order to perpetuate the respect and reverence of future generations that we who have lived and worked with him so surely feel.

Or if knighthood were still in flower, we would bestow upon him that honor—with the admiring accolade of "Dedication, Dignity and Distinction."

It is not only "dedication" in the sense of the naming of a building that I mean in speaking of "dedication, dignity and distinction" . . .

It is dedication in the meaning of devotion.

For here is a servant of the University and the State who has given nearly 40 years of his life to this institution, 23 of them as Dean of the Medical Sciences.

Here is a person whose dignity has been the by-product of an inner integrity which all of us have discerned and respected.

Here is a career which, step by step, year after year, has won the distinction which it deserves—and which, indeed, has been recognized by that great organization, the American Cancer Society with an opportunity for leadership larger even, he has felt, than that which the University could offer.

The satisfaction and reward of any college or university administrator must be largely vicarious. They come from his awareness of the encouragement and support he can give to his colleagues, the teachers, the scholars and scientists of his staff.

Patiently and persistently he has recruited a distinguished faculty—a faculty inspired to make progress, capable of productive teaching and research.

And so clearly this kind of high competence has made itself felt in the total scholarly enterprise of the University as well.

It has upgraded investigation and discovery.

Its interdisciplinary influence has been catalytic on this campus.

These results have been the dividends of an unremitting devotion and dedication.

But they have required the means to make them possible.

The mobilization of financial resources to support the medical science program of the University—from the State Legislature, the Federal Government, countless generous private benefactors and donors, organizations and associations—has been a self-imposed responsibility of Dr. Diehl in his years on the campus as Dean; a responsibility unremittingly undertaken and pursued.

He has been alert to every possibility in this regard—envisioning many of these himself, lending persuasive encouragement and assistance to the efforts and projects of others.

There is an old Latin saying to the effect that "if you would see a man's monument, look about you." The towering success of Dr. Diehl's endeavors we see in the great Mayo Memorial. We see it in the Variety Club Heart Hospital, the Veterans of Foreign Wars and the Masonic Memorial cancer projects, the many buildings and facilities in the provision for which he has been so influential.

Among this company of Dr. Diehl's colleagues and friends, I am sure he is happy to see members of our Minnesota Legislature whose generous understanding and support have helped so greatly to make possible the realization of his high purposes.

At the heart and center of the University's medical program is the training of doctors, and of doctors who will train more doctors.

In Dr. Diehl's years as Dean, the University has awarded the M.D. degree to 2,570 young men and women—and three out of every five of them have been practitioners in Minnesota.
